Conclusions. In this series, dermatological manifestations were detected in the half (52%) of African patients with AIDS. These patients are more likely to present with various cutaneous and/or mucous lesions than AIDS patients in Western countries.

M.B.P.186 BASAL CELL CARCINOMA IN HIV DISEASE

Ian Wilson *, J Barnett *, S Snow **. *Department of Medicine, University of Wisconsin Medical School (Milwaukee Clinical Campus), Milwaukee, WI, USA, **Department of Surgery, University of Wisconsin Medical School, Madison, WI, USA

Objective. To describe an unusually high incidence and atypical presentation of basal cell carcinoma (BCC) in HIV infected men.

Methods. Cases of BCC in HIV infected patients (pts) were collected from a local practice and from 2 dermatologic referral practices.

Results. 6 pts with 14 BCC were seen, all gay white males (1 AIDS, 3 ARC, 1 pre-AIDS, 1 high risk), mean age 40 (range 28-46). 4/6 pts were from a group of 111 HIV infected males followed for 0.1-9.3 years (mean 1.4); 12/14 BCC in this group. 3 facial/11 truncal BCC (F/T ratio=0.3, expected for age and latitude=0.2). One pt developed 8 truncal lesions over 3 years. 57% presented as multiple synchronous BCC (13% expected). 2 pts had small surface lesions but deep tissue invasion. 3 pts had HPV lesions (oral condylomata, perianal condylomata, facial wart) and 2 had molluscum. All were treated by primary excision; 3 also had Mohs chemosurgery. No metastatic or locally destructive lesions have occurred. 8% annual incidence of BCC among white males in the HIV infected group is 100x expected for age and latitude, 6% annual incidence of truncal lesions is 500x expected.

Conclusion. BCC may occur frequently in some HIV infected groups, may present atypically, and should be looked for and treated aggressively. Cofactors such as HPV may be involved.

M.B.P.187 PSORIASIS IN HIV INFECTION: CLINIC, HISTOLOGY AND HLA TISSUE TYPING

Fröschl,Monika; Stallmann,D.; Landthaler,M.; Braun-Falco,O.
Dermatological department of Ludwig-Maximilians-University, Munich, FRG.

Objectives: To determine differences between psoriasis manifesting before HIV infection (group I) and psoriasis occurring after HIV infection (group II). Methods: In a study 4.9 % (16/328) of patients suffering from psoriasis vulgaris were divided into two groups and clinic, therapy, histology and human lymphocyte antigen (HLA) tissue typing were evaluated. Results: Parents were affected in 3/5 of group I patients and in none belonging to group II. All patients - except one group II - showed typical clinical psoriasis. Nail defor-mities were seen in 60 % of group I and 37.5 % of group II. In three patients treated with zidovudine quick improvement of cutaneous lesions could be seen. Histology was typical for psoriasis vulgaris in 2/3 biopsies of group I and 9/12 of group II. HLA tissue typing showed that HLA-Cw6, a sign of hereditary psoriasis with early onset, was present in 3/3 patients group I but only 2/4 group II. Conclusion: Psoriasis in HIV infection even without family history shows typical clinical and histological criteries. HLA-typing seems to be different in the two groups. HIV infection may be an endogenous stimulant leading to provocation or exacerbation of psoriasis vulgaris.

M.B.P.189 NAIL DYSCHROMIA IN ZIDOVUDINE TREATED AIDS/ARC PATIENTS

Don, P.C; Fusco, F.; Fried, P.; Betterman, A.; Duncanson, Frederick P.; Lenox, T.H.; and Klein, N.C. New York Medical College, Metropolitan Hospital Center, New York, New York. U.S.A.

Objective: Define the frequency and parameters of nail dyschromia in AIDS/ARC patients on Zidovudine.
Methods: 38 patients with AIDS or ARC on Zidovudine therapy (AZT) for a mean of 8 months (1-22 month range) volunteered to be evaluated for the development of nail dyschromia. A group of 38 AIDS patients not on AZT and a group of 38 normal patients served as controls.
Results: Sixteen of these 38 (42%) developed progressive nail dyschromia starting on average between 4-8 weeks after initiation of AZT therapy. Most developed longitudinal bands but transverse bands and generalized nail dyschromia were also seen. Color varied from shades of blue to brown-black. The thumbnail was the first nail to develop dyschromia in 11/16 (69%) of patients. Pigment initially appeared at the base of the nail and moved distally. Toenail dyschromia also occurred and followed after fingernail dyschromia. No other area of abnormal pigmentation nor hyperpigmentation was noted. Dyschromia was not associated with sex, having AIDS or ARC, other medications used, nor risk factors for AIDS. Black patients were twice as likely to develop dyschromia 9/12 (75%) vs 8/26 (31%) (p< 0.001 Fisher's exact test) Hispanics ((5/18 (28%)) or Caucasians (3/8 (38%)). Some dark skinned control patients had faint longitudinal brown nail streaks of long duration consistent with normal pigmentation variance in these individuals. This contrasted greatly with the unusual colors and patterns seen in AZT treated patients.
Conclusion: Physicians treating patients with AZT need to be aware of this high frequency of nail dyschromia especially in dark skinned individuals and inform their patients of its possible occurrence in order to facilitate compliance.

M.B.P.191 HUMAN PAPILLOMA VIRUS (HPV) IN ANAL BOWEN'S DISEASE OF HOMOSEXUAL MEN.

Lauwers G.; Cronin W.; Ioachim H.L. Department of Pathology, Lenox Hill Hospital, New York, N.Y. USA.

The incidence of anal carcinoma and lymphomas, uncommon tumors in the general population, are increased in homosexual men. A 5-year review of male patients, revealed 25 cases of anal condyloma (I), 38 cases of squamous cell carcinoma in situ (Bowen's disease)(II) and 15 cases of invasive squamous cell carcinoma (III), between 1980 and 1985.

Confirmed homosexuality was 84%, 65% and 57% and the average age of patients was 32, 37.5 and 49.5 years in groups I, II and III, respectively. AIDS was associated in 14%, 8% and 37.5% of cases. Condyloma was coexistent with 32% of the carcinoma in situ and with 12.5% of the invasive carcinomas. Koilocytotic atypia was present in 72% of carcinoma in situ. HPV antigens were detected by immunoperoxidase staining in 3 of 13 and by in situ hybridization in 6 of 13 cases of anal Bowen's disease in homosexual men.

DNA of HPV type 6/11 was detected in 3 cases and HPV type 16 in 4 cases, one lesion harboring both types 6/11 and 16. HIV antibodies and reversed Th/Ts cell ratios were present in most patients tested. Squamous cell carcinoma in situ generally showed the features of Bowen's disease. The occurrence of anal Bowen's disease in young homosexual males, some HIV positive, and the frequent detection of HPV, suggest an etiologic relationship between HPV and HIV.

M.B.P.188 LES MANIFESTATIONS CUTANEES DE L'INFECTION AU HIV AU RWANDA.

HARELIMANA, Fidèle et BUGINGO,G.
Hôpital Universitaire, Butare, RWANDA.

Plusieurs manifestations dermatologiques sont actuellement associées à l'infection au HIV.

Nous rapportons les résultats de la séropositivité à l'ELISA/HIV parmi les patients adultes consultant le service de Dermatologie-Vénérologie de l'Hôpital Universitaire de Butare-Rwanda de 1986 à 1988.

Sur 543 patients testés, 79% ont été séropositifs à l'Elisa. Un taux de séropositivité relativement élevé a été observé parmi les patients souffrant des dermatoses suivantes : Zona (88%,n=208), prurigo (86%;n=107), dermatite séborrhéique (89%; n=37), dermatose papuleuse prurigineuse généralisée (91%; n=23), "molluscum contagiosum" (87%; n=24), sarcome de Kaposi agressif (100%; n=15), herpès circiné (90%; n=10), herpès génital(86%;n=30), condylomes acuminés (71%; n=78), furonculose (71%; n=31), prurit généralisé (73%; n= 19), urticaire chronique (53%; n=30).

Toutes ces dermatoses bénignes pour la plupart deviennent plus sévères quand elles sont associées à l'infection au HIV. 2 ou 3 de ces dermatoses sont associées chez 120 (28%) malades.
63,6% (n=429) de nos patients séropositifs présentent des manifestations cliniques uniquement dermatologiques et seuls 60 (14%) malades répondent à la définition clinique de l'OMS du cas de SIDA. Ces manifestations cutanées constituent donc des manifestations précoces du SIDA.

Manifestations cliniques
Clinical Manifestations

M.B.P.190 LIPOSOME ENCAPSULATION FACILITATES ENHANCED KILLING EFFECT OF AMIKACIN ON MYCOBACTERIUM AVIUM COMPLEX (MAC) IN BEIGE MICE AND MACROPHAGES

Pattisapu R.J. Gangadharam*; Kesavalu, L.*, Goldstein, J.*, Debs, R.J.*, and Duzgunes, N.** *National Jewish Center for Immunology and Respiratory Medicine, Denver, Colorado and **Cancer Research Center, University of California, San Francisco, California, U.S.A.

We demonstrated that amikacin is effective in eliminating Mycobacterium avium complex (MAC) from beige mice, challenged intravenously with virulent MAC. However, high dose (50 mg/kg) given daily 5 days a week for 8 weeks is needed for this action. When encapsulated in liposomes consisting of phosphatidyl glycerol-phosphatidyl choline-cholesterol (1:1:1 molar ratio), one-tenth of the dose, given in 3 or 4 injections, amikacin effected dramatic reduction in mortality and the number of colony forming units (CFU) of MAC from visceral organs. The amount of drug given via liposome formulation is a fraction of that given by the standard conventional treatment given for the entire period. Thus the antimycobacterial effect per unit dose of drug seen in each tissue is several times more with liposome encapsulation than with the free form. Liposome encapsulated amikacin caused high antimycobacterial activity against MAC inside macrophages and J-774A cell lines, while the free compound showed negligible activity.

M.B.P.192 THREE YEARS OF EVALUATION OF THE CLINICAL CASE DEFINITION OF AIDS IN CENTRAL AFRICA.

A.J.Georges§, L.Bélec§, J.L.Lesbordes§§, M.C.Georges-Courbot§, M.D.Vohito§§, P.M.V.Martin§.
§ Institut Pasteur BP 923 BANGUI - C.A.R.
§§ Centre National Hospitalier BP 934 BANGUI - C.A.R.

Objective : To evaluate and try to improve the WHO clinical case definition of AIDS proposed at Bangui in 1985, through a 3 year period (01.86 to 01.89)
Methods : We have applied the criteria of both the clinical case definition of Bangui and CDC's one to 389 inpatients seen at the National Hospital and distributed into two cohorts of people fitting with each definition.
Results: Using 3 different "scoring" systems for that evaluation there is not a big difference between the results. Among a population of full blown AIDS defined on the basis of the WHO workshop, the empirical scoring system one of us previously proposed in 1985 has, a predictive value of 50% for affirming AIDS.
The usefulness of simple serologic tests such as ELISA is demonstrated : among patients fitting with clinical case definition, the presence of anti HIV antibodies (ELISA) increases the positive predictive value (90.5%).
We were also able to emphasize that neurologic involvement (e.g. Peripheral Facial Palsy, comas, ocular symptoms) poorly taken into account by the Bangui definition, is very common and oftenly serious.
Conclusion : Developing simple serologic tests deeply facilitates the diagnosis in presence of patients recruited on the basis of clinical symptoms only, and in front of atypical clinical symptoms particularly in patients with neurologic disorders.

M.B.P.193 A HIGH INCIDENCE OF ALLERGIC DISORDERS IN PATIENTS WITH HIV INFECTION

Chernoff, David*; Sample, S.**; Lenahan, G.**; Serwonska, M.**; Hollander, H.*; Goetzl, E.*,**.
*Department of Medicine, University of California, San Francisco;
**Department of Microbiology-Immunology, University of California, San Francisco, CA, U.S.A.

Forty seven randomly selected patients with HIV infection were evaluated for allergic disorders. Twenty nine/47 patients (62%) had AIDS-defining opportunistic infections (group 1), 10/47 patients (21%) had AIDS-associated malignancies (group 2), and 8/47 patients (17%) were asymptomatic or had ARC. Of the total group, 41% had a past history of allergic symptoms and 67% reported new or increased allergic reactions. The history of rhinitis and/or conjunctivitis ranged from 75-93% and there was a very high incidence of drug reactions, sinusitis, bronchospasm and radiographic evidence of sinus disease in all clinical groups. Patients in group 1 had significant elevations in serum IgE which did not correlate with the polyclonal elevation of IgG in all groups. In group 1, more patients had positive RAST tests than in groups 2 and 3. The high incidence of allergic disorders in HIV-infected patients suggests that IgE-dependent mechanisms account for their unique susceptibility to other hypersensitivity reactions.

M.B.P.194 ACUTE HIV INFECTION: CLINICAL AND BIOLOGICAL STUDY OF TWELVE PATIENTS.

Sinicco,Alessandro;Palestro,G.;Caramello,P.;Giacobbi,D.;Giuliani,G.;Paggi,G.;Sciandra,M.;Gioannini,P.. University of Turin,Turin,Italy.

Twelve acute HIV infection (6 gays, 2 IVDA, 3 heterosex, 1 nurse with an hospital infection) were directly observed. Mean time between infection and acute illness (8 cases) was 17.7 days ± 3.6 (R. 13-25). All the patients showed a mononucleosis like-syndrome. Symptoms and signs: fever (12/12), polyadenomegaly (11/12), arthralgia/myalgia (9/12), sore throat (9/12), pharingeal enanthema (4/12), rash (7/12), splenomegali (6/12), diarrhoea (2/12), oral candidiasis (2/12), monoarthritis (2/12), polyneuropathy (2/12), meningopolyradiculoneuritis (1/12). Associated pathology: 3 NANB hepatitis, 1 primary syphilis chancre. At admission all the patients were AbHIV- (ELISA). Average time ELISA seroconversion was 56.1 days ±29.3 (R. 24-131). HIVAg was positive in 9/12 (mean persistance: 32.2 days ±12; R. 18-60). The sera of 3 patients without HIVAg, retested after Griswold's method, showed HIVAg. IgM W.B. was positive in 9/12, IgG W.B. in 9/12. CD4+/CD8+ ratio was low for a remarkably increased of CD8+, while CD4+ were slightly decreased. 4 lymphonodal biopsies were performed during acute onset. Histologic and immunohistologic patterns were characteristic. After acute stage (mean duration: 14 days ±8.5; R. 5-30), 10 patients developed PGL, 2 became asymptomatic. After a mean time of 17.2 months ±10 (R. 6-30), 5 patients showed ARC and one of these developed full-blown AIDS and died after 22 months. The follow up suggests a quickly evolution in subjects showing an acute symptomatic HIV infection.

Acknowledgment: this work was supported by the "C. Danagri Foundation".

M.B.P.195 ASPECTS CLINIQUES HIV1 ET HIV2 ET CLASSIFICATION DE BANGUI

Sow Ab.*; Coll Awa Marie*; Faye/Ndao M.A.*; Diouf G.*; Feller-Dansokho E.*; Diop B.M.* et al*.
* Service des Maladies Infectieuses, C.H.U. de Dakar,Sénégal

Objectifs. Evaluer la sensibilité et la spécificité des critères de diagnostic clinique du SIDA HIV1 définis à Bangui et proposer leur élargissement éventuel au SIDA HIV2.

Méthodes. Etude rétrospective de 73 cas de SIDA HIV1-HIV2 hospitalisés de janvier 1986 à décembre 1988 au Service des Maladies Infectieuses du C.H.U. de Dakar. Une cohorte de témoins (patients suspects mais séronégatifs) a été étudiée. Les critères de la classification de Bangui ont été recherchés pour chaque cas et une étude comparative statistique a été effectuée.

Résultats. Sur 73 cas de SIDA :
49 HIV1
21 HIV2
3 double profil

Le sex-ratio est de 2.4. La grande majorité des malades HIV1 comme HIV2 présentent les signes majeurs de la classification de Bangui : amaigrissement > 10%, diarrhée > 1 mois et fièvre > 1 mois. Les manifestations cliniques HIV1 et HIV2 sont comparables dans notre série. Un pourcentage non négligeable de suspects ont eu une sérologie négative (sensibilité ?).

Conclusion. L'élargissement à HIV2 de la classification de Bangui est proposé mais une amélioration est possible.

M.B.P.196 SUIVI PAR IRM DEPUIS OCTOBRE 1986 D'UNE COHORTE DE 50 PATIENTS HIV + INITIALEMENT ASYMPTOMATIQUES

Trotot P.M.,Cabanis E.A,Lavayssière R.,Cabée A.E,Thibierge M., Bigot J.M.,Vignaud J.,Sandoz-Tronca C.,Sansonetti P.J.,Levillain R. Institut Pasteur, Paris, France.

Objectifs: étudier l'histoire naturelle des atteintes encéphaliques au cours de l'infection par le Virus VIH.

Méthode: suivi tous les 6 mois de 50 patients séropositifs, initialement asymptomatiques, par examens cliniques, biologiques et IRM.

Résultats: à l'issue du premier examen, 35 examens IRM normaux, 2 atrophies cérébrales, 13 présentant des zônes de haut signal(ZHS) ponctuées unique ou multiples, contrairement à un groupe témoin. On concluait donc qu'il s'agissait de stigmates d'atteinte précoce du SNC par le VIH (cicatrice ou première atteinte encéphalitique?).

Evolution des images par RM depuis près de 3 ans: ceux qui étaient normaux le sont restés, un des porteurs d'atrophie est décédé de toxoplasmose, l'autre reste inchangé; 12 des porteurs de zones ponctuées sont inchangés, un a vu sa lésion grossir, puis se stabiliser sous AZT et a présenté récemment une toxoplasmose qui a guéri sous traitement.

Conclusion: la cohorte reste constituée, 45 des 50 patients initiaux ont subi le dernier controle. L'évolution clinique se diversifie: 1 décès, 2 toxoplasmoses, 1 pneumocystose, 1 paralysie faciale, une méningite lymphocytaire, un Guillain Barré. Sept sont sous AZT. La surveillance est maintenue, au même rythme.

M.B.P.197 ETUDE DE LA PROTEINE S AU COURS DE L'INFECTION PAR LE VIH.

Lebret-Lerolle, D.* ; Pulik, Marc ** ; Jari, L. * ; Taillet-Thibaud, F. * ; Cannesson, G. * ; Taillet, F. *.
* Hôpital Louis Mourier, Colombes, France; ** Hôpital Victor Dupouy, Argenteuil, France.

Objectif. Etudier la protéine S (PS) au cours de l'infection VIH en raison de sa synthèse partielle par la cellule endothéliale.

Méthodes. Dosages : des facteurs II, V, VII + X par méthode chronométrique en un temps (plasma déficitaire Stago, standard Behring) ; de la PS totale, de la PS libre (après précipitation par PEG, concentration finale 3,75 %), de la C4BP, en Laurell unidimensionnel. Le taux de PS totale est exprimé en % d'un pool référencé Stago. Le taux de PS libre est exprimé en % de la PS libre d'un pool de 11 plasmas normaux techniqués dans les mêmes conditions. Technique de contrôle en bidimensionnel (1è migration en tampon véronal EDTA à pH 9.2, 2è migration identique à la technique unidimensionnelle).

Résultats. 10 patients (5 hommes, 5 femmes), dont 4 toxicomanes, 3 homosexuels, 4 hétérosexuels sont étudiés, âge moyen 29 (21-41) ans. 2 patients ont un SIDA, 4 un ARC, 3 un syndrôme lymphadénopathique, 1 asymptomatique. 5 patients sont sous AZT. Aucun n'a eu d'hémorragie ; 1 patient a eu 4 épisodes de thromboses veineuses profondes avec migration pulmonaire. La PS totale est normale 94.86 % (71-116) de même que la C4BP 102.4 % (80-123), et le rapport C4BP/PS totale 1.079 (0.94-1.28). Par contre la PS libre est basse 32.3 % (0-60). Le II, le V, le VII + X sont normaux (84.8, 81.6, 83.2 %). Chez 2/2 patients le déficit en PS libre est confirmé en bidimensionnel.

Conclusion. Il existe un déficit en PS libre chez 9/10 patients testés. Il n'est pas dû à un déplacement sous forme liée comme en atteste le taux normal de C4BP et du rapport C4BP/PS totale. Il pourrait être en rapport avec une anomalie de synthèse par la cellule endothéliale altérée au cours de l'infection VIH (Kaposi, augmentation du VIII antigène).

M.B.P.198 THE IMPLICATIONS OF HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION AND ACCIDENTAL FALLS (AF) AMONG YOUNG PATIENTS IN A CITY HOSPITAL.

Cheung, Tony W. and Weg, I., Queens Hospital Center, Affiliation of the Long Island Jewish Medical Center, Jamaica, N. Y. 11432, U.S.A.

Objective. To investigate the relationship between AF and HIV infection among young patients.

Methods. Queens Hospital Center is a 600-bed hospital serving patients from disadvantaged backgrounds. The charts of all patients aged 18 to 55 with an accidental fall were reviewed.

Results. Between 1/87 and 6/87, there were 36 AF reported among 29 such patients. Sixteen patients (55.2%) had risk factors related to HIV infection:13 (44.8%) were reported to have been intravenous drug abusers, one came from Haiti, one was homosexual and one frequented prostitutes. HIV antibody were performed on 13 patients; all were positive. Eleven(30.6%) presented with first clinical manifestation of AIDS. The opportunistic infections included Pneumocystis carinii pneumonia(7),esophageal candidiasis(4), CNS toxoplasmosis(1), extrapulmonary tuberculosis (1),cryptococcal meningitis and pneumonia(1). Fourteen (87.5%) of these patients were initially noted to have a normal neurological examination. Neurological deficits were noted later in 5 patients around the time of the falls. Twelve events were related to either febrile and septic episodes. Patients with AIDS were noted usually to have more than one fall. Eight patients (28%) died within one month of the fall.

Conclusion. There is a high incidence of HIV infection among young adults with AF. An accidental fall may be an early sign of an ominous event and may suggest a poor prognosis in these patients.

M.B.P.199 HIV INFECTION NATURAL HISTORY. "PERSISTENT" AND "ACTIVE" FORMS DO EXIST AND THEY ARE CLINICALLY DISTINGUISHABLE.

Montella, Francesco; Di Sora F.; Prepersi F.; Recchia O.; Preite P.A., Recchia G. et al.
Centro per lo studio dell' AIDS e delle Sindromi Correlate. USL RM IV. Roma. Italy.

Objective. To describe natural history of HIV infection and classify HIV seropositive patients with clinical reliability.

Methods. We included in our trial all HIV-seropositive patients who completed at least one year of follow-up. We considered the occurrence, in the first year, of various clinical and laboratory findings (Weight loss; Fever; Herpes Zoster; Hairy Leukoplakia; Seborrheic Dermatitis; Neurological involvement; Oral Candidiasis; Diarrhoea; CD4+< 400/mm3; CD4+/CD8+ ratio< 0.6; IgG> 2500 mg%; Hb< 11 mg%; Thrombocytopenia; WBC< 3000/mm3). For each finding we gave the patient a "Score" of 1. At the end of the first year of follow-up we calculated, for each patient, a "Total Score". Following the model of HBV infection we classified the patients as having "Persistent Chronic Infection" (Score< 4) or "Active" Chronic Infection" (Score> 3).

Results. 140 patients (103 IVDA, 23 Homosex. and 14 Heterosex.) were evaluated. 108 patients reached a Score ranging from 0 to 3 ("Persistent" infection) and 32 reached a Score ranging from 4 to 8 ("Active" infection). Only 5/108 patients having "Persistent" infection (mean follow-up period: 21 months) evolved from LAS to ARC. 27/32 patients having "Active" infection (mean follow-up period: 18 months) evolved from LAS to ARC (in 17 cases) or to full-blown AIDS (in 10 cases)

Conclusions. Our data show an overt clustering of HIV-infected patients in two groups. Some patients progress very slowly or don't progress at all. Others run very quickly through various stages of the illness and reach full-blown AIDS in a short period of time. Clinical manifestations occurring in the first year of the follow-up are helpful to classify the patients in "Persistent" or "Active" form. These findings bear great prognostic and therapeutic implications.

M.B.P.200 HIV-2 IN NEW ENGLAND

Ayanian, J.*; Maguire, J.*; Kanki, P.**; Marlink, Richard**; Mayer, K.***; Essex, M.** *Harvard Medical School, Boston, MA; **Harvard School of Public Health, Boston, MA, USA; ***Brown University, Providence, RI, USA.

Objective: To survey selected populations in New England for exposure to HIV-2

Methods: Individuals at risk for HIV-1 infection (N=850 IVDAs), individuals of West African descent (N=126); individual sera showing indeterminate Western blot testing for HIV-1 (N=111), and individuals suffering from AIDS-like syndromes without definite HIV-1 serology (N=8) were surveyed for HIV-2-specific antibodies.

Results: One individual was seropositive for HIV-2-specific antibodies. This one individual was a 39 year old male originally from the West African region with several years of extensive travel history prior to residing in the United States for the past 7 years. He presented in early 1988 with a 4 month history of anorexia, nausea, vomiting, and watery diarrhea. On physical exam, he was afebrile, had no lymphadenopathy, abdominal tenderness nor occult blood in his stool. Microscopic examination of his stool revealed Isospora belli oocysts. The patient's symptoms resolved on oral trimethoprim/sulfamethoxazole therapy, but returned 5 months later again with Isospora in his stool. This was successfully treated with pyrimethamine. Laboratory examination revealed a persistently low absolute T4 cell count. Serologic evaluation included a negative or indeterminate Western blot and RIPA for HIV-1 and the same assays showing strong reactivity for HIV-2 envelope and transmembrane antigens. His PBMC culture revealed reverse transcriptase activity at 4 weeks and subsequent passage of the isolated virus into continuous T-cell lines has revealed viral proteins consistent with other HIV-2 isolates by Western blot and RIPA.

Conclusions: 1) Evaluation of blood samples from selected individuals in New England has identified one patient with an apparent immunodeficiency associated with HIV-2 exposure, representing the second such case report in the United States. 2) If one assumes the patient was exposed to HIV-2 in West Africa, the case reveals a fairly long latency period prior to his present health problems. 3) Our selected survey, as seen with other broader surveys, has shown that HIV-2 is extremely rare in the United States.

M.B.P.201 CLINICAL AND AUTOPSY FINDINGS IN HIV-1 SEROPOSITIVE PATIENTS.

Afessa, Bekele*; Green, W.*; Olopoenia, L.*; Barnes, S.*; Saxinger, C.**; and Frederick, W.* *Howard University Hospital Washington, DC. U.S.A. **National Cancer Institute, Bethesda, Maryland. U.S.A

Objective. To determine the usefulness of the autopsy in HIV-1 seropositive patients by comparison of discrepancies between the premortem clinical impressions, the clinical cause of death and the autopsy findings.

Methods. Cases for review were obtained from the files of the pathology department of Howard University Medical School. From 1985 through 1988, fifty cases were identified as being seropositive by ELISA and Western blot assays. Clinical histories including premortem diagnoses were available as abstracts from the medical record in the autopsy protocols.

Results. Of the 50 cases reviewed, 41 met the CDC criteria of AIDS; 25 premortem and 16 at autopsy. There were 37 males and 13 females. Mean age was 35.6 years. Risk factors included homosexuality in 22 cases, intravenous drug use (IVDU) in 15, IVDU and homosexuality in 4, blood transfusion in 4 and unknown risk factors in 1 case. The lung was involved in diseases in 37/41 (90.2%) AIDS and 7/9 (77.8%) non-AIDS cases. Diseases diagnosed only at autopsy included PCP (12/22), CMV (9/9), KS (5/7), disseminated MAI (9/13) and bacteremia (7/21). Pathological cause of death correlated with cause of death on the death certificate in 58.5% and 44.4% of AIDS and non-AIDS cases respectively.

Conclusions. The lung was found to be the organ most frequently involved in disease at autopsy. The autopsy diagnosed a significant number (67.2%) of unsuspected and undiagnosed AIDS diseases. Autopsy findings modified the clinical impression of the cause of death in 44.0% of all cases. These findings suggest that the autopsy plays a significant role in quality assurance of diagnoses in HIV-infected patients, both AIDS and non-AIDS.

M.B.P.202 PAIN IN PATIENTS WITH AIDS

Lebovits, A.; Lefkowitz Mathew
Pain Management Service, Department of Anesthesiology, State University of New York Health Science Center at Brooklyn, Brooklyn, NY, USA.

The alarming increase in the transmission of AIDS, as well as its poor prognosis, leaves a critical need to evaluate the prevalence of pain and its current management. A chart review study was therefore undertaken to evaluate these issues in a hospitalized AIDS population.

Ninety-six randomly selected charts of AIDS patients were reviewed in a systematic manner for the prescription of analgesic or psychotropic medication, as well as the location and type of pain. Eighty-two patients were male (85%); mean age was 33.4 years; 44 patients (46%) were diagnosed with AIDS during the admission that was evaluated. The most common AIDS syndrome was Pneumocystis carinii pneumonia (57%). The second most common presenting symptom for this hospitalization was pain (30%).

Fifty-two of the 96 charts reviewed (54%) had at least one note of non-procedural pain or analgesic prescription. The most prevalent location of pain was chest (22%). There were no significant relationships between intravenous drug abuse, specific AIDS syndromes, duration of illness, and the incidence of pain or pain medication prescription. Nearly one-third of patients with pain received codeine (31%), followed by acetaminophen (Tylenol) (27%) and acetaminophen with oxycodone HCl (Percocet). In every instance but one, the scheduling was on an as-needed basis, rather than a fixed schedule.

This study suggests that pain is a major issue in AIDS patients that may be largely overlooked and not managed optimally. A methodology for the prospective evaluation of pain in AIDS patients as well as alternate pain management techniques are recommended.

M.B.P.203 RECURRENT MAXILLARY SINUSITIS IN AIDS PATIENTS.

Hadderingh, Roel J.
Academic Medical Center, University of Amsterdam, the Netherlands.

Objective. The treatment of recurrent maxillary sinusitis in AIDSpatients.

Methods. From 1983 uptil now 311 AIDS-patients have been treated in our hospital. Of this population 35 (12%) had maxillary sinusitis one or more times. The diagnosis was made by clinical examination, radiography, and bacteriological culture. Remarkable was the high incidence of Staphylococcus aureus as cause of the infection. When a patient had a maxillary sinusitis for the first time he was treated with amoxicillin, xylometazoline and steambaths. Despite this conventional therapy the recurrence rate was high: in 28 (9%) of the total population. To avoid repeated treatment with antibiotics we decided to operate patients when they had a maxillary sinusitis for the third time. We made a rhinoantrostoma on both sides, using the technique as has been described by Dr.Buiter. The operationmicroscope was used to have a good view of the operation-field. The stomas were made below the inferior turbinate. Owing to this a good ventilation of the maxillary sinus has been achieved.

Results. Uptil now we have operated 14 patients. The follow up period was 4 to 24 months. We have not seen a recurrence. The patient has to stay only 3 days in hospital, the postoperative recovery is fast, with only less discomfort for the patient.

Conclusion. Surgery seems to be superior to antibiotics in the treatment of recurrent maxillary sinusitis in AIDS-patients.

Pulmonary Manifestations

M.B.P.204 NOCARDIA ASTEROIDES INFECTIONS IN PATIENTS WITH THE ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS).

Cone, Lawrence; Polkinghorn, G*; Woodard, D; Beck, A; Fiala, M; Lynch, R.
Sections of Infectious Diseases and Thoracic Surgery, Eisenhower Medical Center, Rancho Mirage, CA, and *Section of Medical Oncology, Harbor-UCLA Medical Center, Los Angeles, CA, USA.

Aerobic actinomycetes such as mycobacteria, rhodococcus, and nocardia frequently cause disease in immunocompromised hosts including patients with AIDS. Although only a half dozen individuals with nocardiasis and AIDS have been detailed in the literature, we have recently treated 4 patients with pulmonary nocardiasis, 2 of whom had brain involvement. In 3 the diagnosis was only established by invasive techniques (bronchoscopy, closed and open lung biopsy). Chest x-rays revealed lobar infiltrates which showed intense uptake with gallium^{67}, although simultaneous brain abscesses in 2 went undetected by the same isotope study. Three of 4 individuals could not be treated with sulfonamides due to allergy or severe pancytopenia. All received multi-drug therapy with minocycline, netilmicin and imipenem to which the organism showed excellent in vitro sensitivity. Two patients recovered fully on this regimen and 1 improved. We conclude that invasive studies are often needed to establish a diagnosis of nocardiasis in patients with AIDS, and alternative multi-drug regimens are effective treatment in individuals unable to tolerate sulfonamides.

M.B.P.205 PROLONGED HEALING OF SPONTANEOUS PNEUMOTHORAX AND SCLEROTHERAPY IN AIDS PATIENTS

Jacobson SJ[*], McGowan K[* **], Scheib R[**], Schwaitzberg S[* **], and Quinn C[*]; [*]Tufts-New England Medical Center, and [**]Lemuel Shattuck Hospital, Boston, MA, USA.

Objective: Review the outcome of spontaneous pneumothorax in AIDS patients. Methods: Retrospective review of known PTX cases in 2 institutions in 1988. Results: Spontaneous pneumothorax is a recently recognized occurrence in patients with AIDS, having been noted during episodes of pneumocystis carinii pneumonia (PCP). Pleurectomy for persistent air leaks has been performed successfully. We report the successful outcome of sclerotherapy (with tetracycline or talc) for persistent air leaks. Brief case outlines:

	Lung Disease					
Pt	Prior	Active	Length PTX	ScleroRx	Complications	Outcome
1	PCP x 3	no	30 d.	TCN	wound infec'n	resolut'n
2	bronchitis	PCP, crypto	16 d.	TCN	wound, sepsis	death
3	PCP, hx PTX	prob. PCP	25 d.	TCN, talc	none	resolut'n
4	PCP, bact. pneumonia	pleural PCP bact. pneum.	#1:43 d. #2:>38 d.	no no	multiple chest tubes	alive with chest tube

Conclusion: All PTX were significant and required CT placement. PTX, sometimes recurrent, have been seen in AIDS patients with previous underlying lung disease, frequently prior episodes of PCP. Active lung disease was usually present. Aerosolized pentamidine prophylaxis was used in 3 of 4 patients. Healing of the PTX was prolonged. Tetracycline or talc pleural sclerotherapy was frequently successful and avoided pleurectomy. Complications included chest tube site infections and consequent sepsis. Agressive therapy of PTX with sclerotherapy is recommended.

M.B.P.206 ROLE OF HIV INFECTION IN ALTERATION OF PULMONARY FUNCTION IN INTRAVENOUS HEROIN ADDICTS (IHA).

Foresti Valeriano, Villa A, Guareschi G, Parisio E, Scolari N, Pedicorni AM.
Fatebenefratelli Hospital, Milan, Italy.

Objective. IHA and patients (pts) with AIDS frequently develop interstitial lung disease. In IHA HIV infection could represent a cause of further pulmonary damage. We studied a group of IHA, to evaluate the role of HIV infection in alteration of respiratory function (RF). Methods. RF tests, blood gas analysis and CD4 lymphocytes counts were performed in 33 IHA, with no pulmonary symptoms and normal chest x-rays, 23 male and 10 female, 12 HIV- and 21 HIV+. 6 belonging to group II of CDC classification system, 11 to group III and 4 to group IV. Results. Only DLCO expressed as percent of the predicted (74.6 ± 14.1 % vs 86.9 ± 6.6 %, $p<0.01$) and CD4 lymphocytes ($785 \pm 428/mm^3$ vs $1236 \pm 464/mm^3$, $p<0.01$) were significantly lower in HIV+ pts than HIV- pts. DLCO was <80% in 15/19 (79%) HIV+ pts and in 1/11 (9%) HIV- pts. The 4 HIV+ pts with normal DLCO (>80%) were in group III and IV of the CDC classification. Conclusions. These data show that HIV+ IHA had significant reduction in DLCO in comparison to HIV- IHA. The absence of clinical symptoms and/or radiological abnormalities of pulmonary disease suggests a subclinical pulmonary infection or alveolitis caused by HIV. Since DLCO abnormalities, that we mostly find in HIV+ IHA, are present in the asymptomatic stages of the infection and are not related to CD4 lymphocytes reduction, we suggest that interstitial lung involvement can be due to a direct action of the virus rather than to a subclinical opportunistic infection.

M.B.P.207 PNEUMOTHORACES IN PATIENTS WITH AIDS

Sepkowitz, Kent; Telzak, E.E.; Carrow, M.; Dickmeyer, M.; Bernard, E.; Gold, J.M.W. et. al.
Memorial Sloan-Kettering Cancer Center (MSKCC), New York, New York, USA.

Objective: To describe the natural history and risk factors for a poor outcome in patients with AIDS who develop pneumothoraces.
Methods: Cases of pneumothorax (PTX) in patients with AIDS were reviewed and their medical histories were abstracted onto standardized forms. To maximize case finding, all patients with a discharge diagnosis of "PTX" from 1980 - 1988 at MSKCC were crossmatched with a hospital-based AIDS registry.
Results: Of 1130 patients with AIDS, at least 11 (1%) have had a PTX and, of these, 7 have had pneumothoraces in both lungs. Ten were male and 9 had concurrent *Pneumocystis carinii* pneumonia (PCP). Eight (73%) patients had a good outcome (left the hospital); however, of these, 3 required sclerosis and one required a thoracotomy. Three (27%) patients died. Those who died were more likely to have a history of previous non-infectious pulmonary disease (3/3 vs. 1/8; p=.02), to have > =3 pathogens isolated from their lung and appearing to cause infection during their PTX (3/3 vs. 0/8; p=.006) or to be smokers (3/3 vs. 3/8; p=NS).
Conclusions: PTX in patients with AIDS appears associated with PCP. It has a high morbidity and is associated with a high mortality. Risk factors for death include a history of non-infectious pulmonary disease and multiple pathogens isolated from and appearing to cause infection in the involved lung.

M.B.P.208 SPONTANEOUS PNEUMOTHORAX IN AIDS PATIENTS ON PROPHYLACTIC AEROSOLIZED PENTAMIDINE.

Glenn S. Newsome*, MPH, MD, Douglas J. Ward**, MD, Phillip F. Pierce*, MD. *Georgetown University Hospital and **George Washington University Hospital, Washington, DC, U.S.A.

Pneumocystis carinii pneumonia (PCP) is the most frequent pulmonary complication in AIDS. The development of spontaneous pneumothorax is a complication of PCP. In order to assess the risk of pentamidine prophylaxis, two groups were retrospectively examined. Group I consisted of 327 patients who received aerosolized pentamidine prophylaxis (pentamidine 100 mg via "Respigard II" nebuliser system every other week). Group II was 35 patients who received parenteral (4 mg/kg monthly) prophylaxis. Both groups had similar demographic characteristics. In Group I there were 8 pneumothoraces while there were no pneumothoraces in Group II (Fisher's p=0.48). The duration of aerosolized prophylaxis ranged between 3 to 13 months. Bilateral pneumothoraces were present in 50%. The majority of the patients with pneumothoraces had evidence of active PCP (75%) and cystic lung disease (62%). Chest tube evacuation was required in 75% and 38% of patients died of progressive respiratory failure.

In conclusion, our retrospective review show no statistically significant increase in number of pneumothoraces in AIDS patients receiving aerosolized pentamidine. The occurrence of pneumothorax in these patients represents poorly controlled infection rather than a direct result of aerosolized pentamidine.

M.B.P.209 FATAL ADVERSE REACTION WITH INDUCED SPUTUM IN PATIENTS WITH PLEURAL EFFUSIONS.

NELSON. MARK. R. SMITH.D.E. HAWKINS.D. GAZZARD.B.G.
ST.STEPHENS HOSPITAL, FULHAM ROAD, LONDON, ENGLAND.

OBJECTIVE: To report possible life threatening adverse reactions with sputum induction and /or bronchoscopy in HIV patients with suspected Pneumocystis Carinii Pneumonia (PCP) and concurrent pleural effusions.
METHOD: All patients investigated by induced sputum and /or bronchoscopy for PCP over a six month period had a chest x-ray prior to and post investigation.
RESULTS: Of 83 investigated patients, 28 had documented Kaposi's Sarcoma (KS) or lymphoma. 4 of these 28 had a pleural effusion. These 4 patients underwent sputum induction, followed by 2 who had bronchoscopy. All 4 patients had marked worsening of their pleural effusion with increasing dysnoea. Two of the patients died within 24 hours (4 and 16). Necroscopy showed pulmonary KS with pleural involvement in one and pulmonary lymphoma in the other. The others responded initially to insertion of intercostal drain but died at 28 and 31 days from respiratory complications. No other patient with or without KS or lymphoma developed a pleural effusion following investigation. In none of the 4 patients was pneumocystis documented on sputum induction or BAL, or were KS seen.
CONCLUSION: Induced sputum may give rise to potentially life threatening pleural effusion in patients with minor effusion resulting from KS or lymphoma.

M.B.P.210 CELL DIFFERENTIALS IN BRONCHOALVEOLAR LAVAGE (BAL) AND TRANSBRONCHIAL LUNG BIOPSY (TBLB) FROM PATIENTS WITH ADVANCED HIV INFECTION AND DIFFUSE PULMONARY INFILTRATES.

Rust, Michael G.[°]; Schneider, M.[°°°]; Kronenberger, H.[°]; Falk, S.[°°°]; Helm, E.B[°°]; Meier-Sydow J.[°].
[°]Div. of Pneumology and [°°]Infectious Dis., Dept. Internal Med. and [°°°]Dept. of Pathology, Hospital of J.W. Goethe-University, Frankfurt/M, FRG.

Objective of the study: To compare cell differentials in BAL with histologic findings we performed TBLB and BAL with 300 ml NaCl concurrently in 90 HIV patients with P. carinii pneumonia (PCP) and 60 HIV patients with other diffuse pulmonary infiltrates (144 male, 6 female, age: 38±10 years). Methods: Cell differentials (Lymph-BAL [%] and PMN-BAL [%]) were performed on cytocentrifuge slides (Wright Giemsa stain) of BAL. We counted 1000 cells. Biopsies were taken using fluoroscopic guidance. The specimens were graded as showing accumulation of mononuclear cells (MON-C), widened alveolar walls (WAW), alveolar exudate (EXU), signs of CMV infection (CMV).
Results:

	N	MON-C	WAW	EXU	Lymph-BAL	PMN-BAL
PCP	90	36%	49%	84%	17±15%	9±14%
Non-PCP	60	47%	36%	7%	14±11%	5±11%

Neutrophilia in BAL was related to alveolar exudate on TBLB and presence of P. carinii (ANOVA, p<0.01). No other relations between BAL and TBLB were found. We conclude that accumulation of mononuclear cells and widening of alveolar walls not related to PCP are frequent in TBLB of patients with advanced HIV infection and diffuse pulmonary infiltrates. We suggest that they may reflect a "non-specific interstitial pneumonitis".

M.B.P.211 SPECTRUM OF PULMONARY DISEASES ASSOCIATED WITH THE ACQUIRED IMMUNO DEFICIENCY SYNDROME

Weinke,Thomas; Scherer,M.; Ortmann,C.; Pohle,H.D.

Universitätsklinikum Rudolf Virchow, Freie Universität Berlin, FEDERAL REPUBLIC OF GERMANY

Objective. Pulmonary abnormalities are a major source of morbidity and mortality in AIDS patients. Therefore, we evaluated 184 AIDS patients to assess the incidence and spectrum of pulmonary disease associated with AIDS.
Methods. By means of a prospective protocol all 184 patients with full-blown AIDS underwent chest radiography and a careful clinical examination; if indicated sputum analysis and bronchoscopy with bronchoalveolar-lavage were performed. Lavage fluid was processed for bacterial, fungal, mycobacterial and parasitic stains and cultures. Similarly post-mortem biopsies of the lung were handled.
Results. In 127 out of 184 (69.0 %) AIDS patients pulmonary manifestations could be detected. These manifestations had an infectious cause in 111 individuals (87,4 %), an infectious and neoplastic cause in 9 (7,1 %) and a neoplastic cause in 7 patients (5,5 %). More than one pulmonary manifestation could be detected in 47 patients (37,0 %).
The frequency of the various infections and neoplastic pulmonary manifestations is listed up: Pneumocystis carinii 79 (62,2 %), CMV 35 (27,6 %), MAI-complex 33 (26,0 %), Kaposi's sarcoma 14 (11,0 %), M. tuberculosis 14 (11,0 %), Cryptococcus neoformans 9 (7,1 %), bacterial pneumonia 5 (3,9 %), Non-Hodgkin lymphoma 4 (3,1 %), Strongyloides stercoralis 1 (0,8 %).
Conclusion. Pneumocystis carinii is the most frequent and dangerous pathogen which effects the lung. Significant pulmonary disease was present in most patients but varied markedly with the etiologic agent. A differentiation between colonization and disease is especially important in infections with CMV and atypical mycobacteria. Other less frequent causes of pulmonary disease must be kept in mind.

M.B.P.212 FIBEROPTIC BRONCHOSCOPIC DIAGNOSIS OF PULMONARY DISEASE IN 171 HIV-INFECTED PATIENTS

J.ANCOCHEA;D.PADILLA;J.GARCIA [illegible];P.[illegible];[illegible];L.JIMENEZ.
Department of Pneumology,Microbiology,Internal Medicine, H.Princesa,MADRID,SPAIN.

We prospectively analyzed 171 episodies of pneumonitis in 153 patients anti-HIV (+). The pneumonitis was defined by clinical and radiografic criteries. We have obtained 168 bronchoscopy aspiration (BA), 164 bronchoalveolar lavage (BAL), 117 bronchoscopic-protected catheter brush (CB) and 82 transbronchial biopsies (TB). The samples were procesed for microbiological and anatomopathological studies by standard methods. The bacterial growth was considered significative according to these criteries: BA > 10-5 CFU/ml.; CB > 10-3 CFU/ml.; BAL > 10-5 CFU/ml. and <1% squamous epithelial cells. Any orophoringeal bacterial growth was considered as contamination. The results were as follows:

	BA	CB	BAL	TB	DIAGNOSIS
-H.influenzae	8/9(*)	3/4	8/9	1/1	9
-S.pneumoniae	2/4	0/3	3/4	-	4
-Legionella sp.	2/8	2/7	7/8	-	8
-Others bacteria	5/8	6/7	5/7	-	8
-Mycobacteria(**)	12/23	6/18	18/22	5/11	19
-H.capsulatum/C.neoformans	1/3	1/3	3/3	2/2	3
-P.carinii	-	-	71/71	28/37	72
-Cytomegalovirus(***)	-	-	17	-	
-Pulmonary Kaposi's sarcoma	-	-	-	3	3
-Contamination	63%	11	18%	-	

(*)Number of positives by the method/ number of positives by any other method.
(**)16 M.tuberculosis and 3 M.avium-intracellulare.
(***)14 by cellular culture and 3 by inclusion bodies in BAL.
More than one diagnosis: 18 episodies.

31 episodies (18%) were not diagnosed. Out of 31 episodies, 8 have normal chest X-Rays, 48% of the 31 episodies had received antimicrobial agents previously, 90% of the 31 episodies were intravenous drug abusers. CONCLUSIONS: 1.- The fiberoptic bronchoscopy methods are accurate procedures for the diagnosis of pulmonary disease in HIV-infected patients. 2.- The BAL, as having been previously described, can diagnose bacterial respiratory infection in these patients.

M.B.P.213 EARLY DETECTION OF PUMONARY COMPLICATIONS IN AIDS-PATIENTS: VALUE OF LUNG FUNCTIONTESTS (LFT) AND NUCLEAR MEDICINE PROCEDURES (NMP).

Christine Armbruster, N. Vetter, H. Köhn.
II. Int. Lungenabteilung, Pulmologisches Zentrum der Stadt Wien, Vienna, Austria.

Aim of the study was the evaluation of LFT and NMP in early detection of pulmonary complications in AIDS-patients.
38 HIV-AB pos. patients were examined every six weeks by LFT (PO$_2$, PCO$_2$, AaPO$_2$-difference, CO-diffusion capacity (DLCO), bodyplethysmography) and by NMP (67-Gallium-scan, 99 mTc DTPA-lung clearance) during a 14 months period. Pulmonary complications occured in 21 patients (14 PCP, 8 CMV, 5 TB, 1 LIP, 2 KS), 17 patients had no pulmonary disease.
The results showed a high sensitivity and specificity for DLCO, 99 mTc-DTPA lung clearance and 67-Gallium-scan.

Table:

Procedure	sensitivity	specificity
PO$_2$/aaPO$_2$/DLCO	71%/71%/93%	100%/71%/75%
99m-Tc-DTPA/Galliumscan	93%/86%	62%/69%

Comparing the two groups of patients every parameter differed significantly ($p < 0,005$) except PCO$_2$, TLC and FEV 1.
We conclude, that DLCO, 67-Gallium-scan and 99 mTc-DTPA lung clearance are the most effective means in early detection of pulmonary complications in AIDS.

M.B.P.214 VALUATION OF THE CELLULAR POPULATIONS IN THE BRONCHOALVEOLAR LAVAGE (BAL) FROM HIV-INFECTED PATIENTS WITH PNEUMONITIS BY VARIOUS ETHIOLOGY.

J.ANCOCHEA;C.JIMENEZ;C.LOPEZ [illegible];D.PADILLA;[illegible];M.L.JIMENEZ.
Department of Pneumology, Microbiology, Pathology and Internal Medicine, Hospital de la Princesa, MADRID, SPAIN.

We prospectively analized a control group of twenty-three HIV (-)-normal patients without infection pulmonary disease and seventy-one HIV-infected patients with pneumonitis. Both groups are homogeneous as to the habit of smoking. The infection ethiology, by groups, were as follows

-Group 1.- Controls (n=23).
-Group 2.- P. carinii pneumonia (n=43).
-Group 3.- Bacterial pneumonia (n=12).
-Group 4.- Bacterial and P.carinii pneumonias (n=7).
-Group 5.- P.carinii pneumonia with cytomegalovirus isolation in the BAL (n=7).
-Group 6.- Patients with P.carinii pneumonia that have died during the following month of the diagnosis (n=8).
-Group 7.- Patients with P.carinii pneumonia that have not died during the following month of the diagnosis (n=36).

We have only valued the differential cell counts by means of the Wright-Giemsa stain on 400 cells. The signification of the differences between groups have been made by unpaired Student t test .

The results statistically significances were as follows:
1.- The groups 2, 3 and 4 as to the control group have decreased the number of macrophages and have increased the number of lymphocytes and polymorphonuclears. 2.- Group 5 as to group 1 have decreased the number of macrophages and have increased the number of lymphocytes. 3.- Group 5 as to group 2 have increased the number of macrophages, it suggest that there is a modulation of the inflammatory response, due to the presence of the cytomegalovirus. 4.- Our findings show, in the group of patients with P.carinii pneumonia who died in the followings four weeks at the time of diagnosis, an increase of the polymorphonuclears percent versus the group of patients with the same diagnosis that did not die at this time.

G.I., Liver/Hepatitis and Other Manifestations

M.B.P.215 CHRONIC HBeAg POSITIVE HEPATITIS IN HIV INFECTION.

Antonietta, Cargnel; Viganò P.; Gubertini G.; Meraviglia P.; Mezzenzana M.A.; Zanchetta N.°
2nd Dept. of Infectious Dis.; ° Dept. of Hygiene; L.Sacco Hosp.; Milan; Italy.

Objective: To evaluate the role of HIV infection on the evolution of HBV chronic hepatitis. Methods: Clinical, biohumoral and histologic features of 20 HIV Ab+ pts. with CH HBeAg +, without opportunistic infections,were compared with an analogous group of HIV Ab negative ones. Results: No significant clinical and biochemical differences appeared at the comparison between the two groups. The serologic and immunohistochemical markers are shown in the table.

HIVAb	pts	HBeAg(serum)		HDVAbIgM(serum)		HDVAg(serum)		HBcAg(liver)		HDVAg(liver)	
	n	n	%	n	%	n	%	n	%	n	%
pos.	20	9	45*	9	56.3	2	12.5	13	81	8	40*
neg.	20	2	10	6	60	1	10	9	90	1	5

Conclusions: The markers of HBV active replication are present at a significantly higher degree in HIV Ab positive patients (*p<0.01), whereas the replication features of HDV don't seem to be modified by HIV Ab presence. When HDV infection is present the histologic damage is always heavy and not conditioned by HIV positiveness. On the contrary, the presence of HIV Ab seems to correlate with less severity in histologic damage in patients without Delta infection (2 CPH, 2 mild CAH among HIV Ab positive patients; 2 CPH, 3 mild CAH, 3 severe CAH and 2 cirrhosis among HIV Ab negative patients).

M.B.P.216 CHRONIC HEPATITIS IN HIV INFECTED PATIENTS

Caredda,Francesco*; d'Arminio Monforte,A.*; Antinori,S.*;Gaiera,G.**; Vago,L.** and Parravicini C.**
*Infectious Diseases Clinic, **V Chair of Pathology,University of Milan,Italy.

Objective. To study the chronic hepatitis in HIV infected patients.
Methods. HIV antibodies were tested by ELISA (Sorin). Positive results were confirmed at Western Blot (Du Pont). Serological HBV and HDV markers were assayed by RIA (Sorin). The CDC classification for HIV infection has been used.
Results. 43 patients underwent liver biopsy for diagnostic investigations. 29 of them were in the II or III group. The other 14 patients were in the IV group. Other 32 patients underwent autoptical examination. 38.7%(29/75) of the total patients were HBsAg-pos. In 19 of them there was evidence of HDV infection. In the table are reported the numbers of HBsAg-pos. and HBsAg-neg. patients at various stages of HIV infection with evidence of CAH or cirrhosis.

	HBsAg-positive	HBsAg-negative	Total
II or III	13/14 (92.9%)	8/15 (53.3%)	21/29 (72.4%)
IV	3/6 (50.0%)	2/8 (25.0%)	5/14 (35.7%)
Autopsy	4/9 (44.4%)	5/23 (21.7%)	9/23 (33.1%)
Total	20/29 (68.9%)	15/46 (32.6%)	

Conclusion. CAH or cirrhosis are common in anti-HIV pos. patients and particularly in HBsAg-pos. individuals in CDC groups II or III, and in these cases it should be considered the oppurtunity of a treatment with artiviral drugs.

M.B.P.217

REACTIVATION OF ACUTE HEPATITIS B IN AIDS

Roberto Luzzati, G.Di Perri, M.Malena, E.Rossi, P.Iuzzolino* and D.Bassetti. Institute Infect.Diseases, Verona *Deparment Pathology, Verona, Italy.

Objective. To investigate the role of HIV on the outcome of HBV infection, we describe a reactivation of acute hepatitis B in a patient with AIDS.

Methods and Results. The patient was a 26 years old male, drug addict. HBs Ag, anti-HBs, HBe Ag and anti-HBe, antibodies to the delta Ag were assayed by radioimmunoassay. Serum HBV DNA was detected by spot hybridization. In 1982 the patient had acute hepatitis B and appeared to recover fully clearing HBs Ag, HBe Ag and HBV DNA. The activities of his liver enzymes were persistently in normal range. He presented PGL and ARC, respectively in June 1986 and in January 1987. Full-blown AIDS (cerebral toxoplasmosis) developed in July 1987 and then the patient received long-term zidovudine and sulfamethopirazine/pyrimethamine therapy. In June 1988 acute hepatitis B recurred with AST) 2000 U/l, clinical jaundice, progressive hepatic failure and death. Markers of acute HBV infection including HBs Ag, HBe Ag and HBV DNA, reappeared while delta-Ab was persistently negative. The post-mortem liver biopsy was consistent with confluent hepatic necrosis.

Conclusion. Reinfection with another HBV subtype is unlikely. This pattern strongly suggests a late reactivation of HBV. Thus, although the virus is presently not thought to be directly cytotoxic for liver cells, acute hepatitis B may still reappear in the course of AIDS.

M.B.P.219

CORRELATION BETWEEN HIV AND HBV INFECTIONS.

Sinicco, Alessandro; Valle, M.; Santoro, A.; Scolfaro, C.; Cariti, G..
University of Turin, Turin, Italy.

Objective. HIV and HBV infections: possible interactions.

Methods. 660 AbHIV+ (IVDA:76.3%;homosex:13.3%;blood recipients:3.6%;others:13.3%) were tested for HBV-markers, immunological and clinical findings. 242 were followed up for 24 months (±8.3). 18 had hepatic biopsy.

Results. 485 were positive for HBV-markers: 65 HBsAg+ (21 AbHDV+); 332 AbHBs+ and AbHBc+; 63 only AbHBc+. 19% of the followed up AbHBs+ and AbHBc+ patients lost the positivity for AbHBs. 14 showed a primary HBV infection: 6 with clinical evidence of acute hepatitis (only 7 became AbHBs+). The hepatic biopsies revealed 8 CPH and 10 CAH.

Conclusion. High presence of HBV-markers in AbHIV+ patients (in prevalence IVDA). Frequently loss of AbHBs (especially in AbHDV+); frequently reappearance of HBsAg in the AbHBc+ carriers. Reduced onset of AbHBs and perseverance of HBsAg in primary HBV infection. Positive markers of viral active replication in chronic hepatitis with low levels of cytolysis and reduced histological injury in sequentially biopsied patients. HBV infection doesn't seem to condition HIV infection in a shorttime.

Acknowledgment: this work was supported by the "C. Denegri Foundation".

M.B.P.221

INFLUENCE OF HIV INFECTION IN HEPATITIS DELTA CHRONIC CARRIERS.

Castillo, Inmaculada; Bartolomé, J.; Martínez, MG.; Madejón, A.; Porres, JC. and Carreño, V. Hepatology Unit. Fundación Jiménez Díaz. Madrid (SPAIN).

HIV infection is very usual among intravenous drug abusers (IVDA). On the other hand, drug addiction is one of the most important way of transmission of the Hepatitis Delta Virus (HDV). For these reasons, the aim of the present work was: to study the influence of anti-HIV positivity in HDV replication, as well as in the simultaneous presence of HDV and Hepatitis B Virus (HBV).

Forty three anti-HD positive patients were included. Most of them were IVDA (44%) and the rest referred parenteral exposure (14%), negative enquire (14%), transfusion (7%), household contacts (7%) and homosexuality (5%). Anti-HIV was detected by Western-blot. Serum Delta antigen (HDAg) was tested by immunoblot and HDV-RNA was determined by slot-blot hybridization using a ^{32}P-HDV-RNA obtained from the [illegible] vector.

Out of the 43 patients, 15 (35%) were anti-HIV positive (14 IVDA and 1 homosexual). All of them were asymptomatic and 2 presented serum p24. With respect to the HDV markers, there were no differences between these subjects with or without HIV infection, neither in the presence of serum HDAg (67% vs 71%, respectively) nor in the IgM anti-HD positivity (47% vs 46%, respectively). In contrast, HDV-RNA was detected in 14/15 (93.3%) anti-HD positive cases with anti-HIV and only in 16/28 (57.1%) anti-HIV negative ones (p < 0.01). The simultaneous replication of HBV and HDV (HBV-DNA and HDV-RNA positivity) was found in a significant higher percentage (p < 0.05) in those HIV-seropositive patients (9/15: 60%) than in the negative cases (5/28: 18%). The same occurred with the simultaneous presence of HBV-DNA and HBeAg: 40% in the anti-HIV positive subjects vs 18% in the anti-HIV negative patients (p < 0.05).

In conclusion: HDV-RNA was detected in a higher percentage among HDV carriers with HIV infection. Moreover, in these patients, the simultaneous HBV and HDV replication was more frequently observed. During the follow-up, it will be compared the clinical evolution of both group of anti-HD positive patients (with and without HIV infection).

M.B.P.218

HIV INFECTION AND DELTA HEPATITIS IN INTRAVENOUS DRUG ADDICTS

Lake-Bakaar, G. Bhat, K. and Govindarajan, S.* SUNY-Health Science Center, Brooklyn, New York and *Rancho Los Amigos Medical Center, Downey, California, U.S.A.

The recently suggested close correlation between HIV and delta hepatitis virus (HIV) may merely reflect high double-exposure rates in promiscuous homosexuals.

Objective To correlate delta markers with stage of HIV disease in intravenous drug addicts, IVDA.

Subjects Eighty-two IVDA: 35 with AIDS, 30 HIV positive and 17 HIV negative.

Methods HIV antibody measured by repeat Elisa testing (Abbott). Total anti-HDV (Abbott); IgG anti-HDV, IgM-anti-HDV and delta antigen (RIA); HBsAg, anti-HBs and anti-HBc (Abbott RIA).

Results 1) Seventeen subjects tested positive for anti-HDV by Abbott Elisa; six of the 17 were HBsAg positive. Only the six HBsAg positive subjects were IgG and IgM anti-HDV positive.

2) IgM anti-HDV was present in 2 of 17 (11.8%) HIV negative, 4 of 30 (13.3%) HIV positive, but none of 35 AIDS subjects (p = 0.035, Fisher's exact test; AIDS vs non-AIDS)

Conclusions The data suggest a high false positive rate of anti-HDV in non-HBsAg positive sera with the Elisa technique and that anti-HDV production (IgG and IgM) may be lost in IVDA with AIDS.

M.B.P.220

MODULATION OF VIRAL HEPATITIS IN HIV-1 INFECTION

Rossol S., Voth R., Meyer zum Büschenfelde K.H. and Hess G.
I. Medizinische Klinik und Poliklinik der Johannes Gutenberg Universität Mainz, FRG.

OBJECTIVE: To study the outcome of HBV infection in HIV-1 infected patients.

METHODS: In a group of 306 HIV-1 infected patients 214 (70 %) had evidence of prior HBV infection. Homosexuals and i.v. drug abusers compose greater than 90 %. The prevalence of chronic HBV carriers, as determined by HBsAg positivity for longer than 6 months among HIV-1 infected patients yielded in 13 %.

RESULTS: Our data demonstrate low activity of SGOT and SGPT in patients coinfected with HIV-1 virus. Individuals suffering from chronic active hepatitis, symptomatic HIV-1 infection and T4 counts lower than 400 cell exhibit significantly increase of HBV-DNA in contrast to asymptomatic HIV-1 and HBV infected individuals. On the other hand HIV infected patients tend to have a mild course of chronic hepatitis.

CONCLUSION: Our data show evidence that suppression of cellular immunological reactions had beneficial effects on the clinical and histological outcome of HBV infection. However, there are no data showing any spontaneous clearence of HBV in AIDS patients. One might therefore expect that there is a correlation between markers of cellular immunity like T4 and T8 positive cells in HIV-1 infected patients and the clinical course of chronic HBV infection.

M.B.P.222

THE EFFECT OF HIV ON CHRONIC HEPATITIS B: A STUDY OF 150 HOMOSEXUAL MEN

Bodsworth Neil, Donovan B. Dept of Public Health, University of Sydney, 2006. Australia.

Objective. To determine the influence of concurrent HIV infection on chronic HBV infection.

Method. Serum markers of HBV replication (HBeAg and HBV-DNA) and disease activity (alanine transaminase, ALT) were analyzed for 150 male homosexual chronic HBsAg carriers, 82 (54.6%) of whom tested positive for antibodies to HIV.

Results. Subjects positive for HIV antibody were more likely to express HBeAg (62 of 80 cases) and HBV-DNA (52 of 67) in their sera than HIV seronegatives (35 of 67 ($p<0.001$) and 35 of 70 ($p<0.0005$) respectively). The degree of immune suppression however, did not seem to affect the influence of HIV on HBeAg/HBV-DNA expression. In HBeAg seropositive subjects, concurrent HIV infection was associated with lower serum alanine transferase (ALT) levels ($p<0.005$). This effect increased relative to the degree of immune suppression as determined by diminished CD4 lymphocyte counts. Conversely, in patients not expressing HBeAg in serum there was a weak trend ($p=0.130$) towards higher ALT levels with concurrent HIV.

Conclusion. This study suggests that whilst chronic hepatitis B may be less severe when accompanied by HIV infection, greater viral replication may make it more contagious and resistant to antiviral therapy. These data support an immune mediated pathogenesis for hepatitis B and have implications for its control.

M.B.P.223

LIVER DISEASE IN PATIENTS WITH AIDS

BRANDÃO-MELLO,C.E.*; SILVA,M.A.*; CORREIA LIMA,M.B.*;BASILIO, C.A.*; GONZAGA,A.L.**.
* Hospital Gaffrée e Guinle - Universidade do Rio de Janeiro,Brasil
** Centro de Hematologia Santa Catarina - Rio de Janeiro, Brasil.

.The evaluation of clinical, biochemical, serological and morphological data of liver involvement in high risk groups patients with was the aim of this work. Our purpose was to determine the spectrum of liver disease in AIDS and the clinico-morphological correlation in order to ascertain if any clinical or pathological feature was characteristic of AIDS.

Material: We have evaluated 81 patients with AIDS, being 20 hemophiliacs (18 A and 2 B) severely affected and 61 homosexual men.

Methods: We studied hepatitis B virus (HBV) serum markers by commercial RIA kits for the detection of HBsAg,Anti-HBs,Anti-HBc,HBeAg and Anti-HBe. Liver function tests including aminotransferases,total bilirubin,alkaline fosfatase were performed. Mostly of the liver biopsies were obtained percutaneously ,but some samples were obtained from autopsy material.

Results: The great majority of the patients were anicteric. More than 80% of the sera were Anti-HBs and Anti-HBc (+) . Serum aminotransferases levels were mildly elevated(less than twice the upper limit of the normal range) in the majority of the patients. Chronic persistent hepatitis,chronic active hepatitis and cirrhosis were the most frequent findings in hemophiliacs. Granulomas due to M.avium and M.tuberculosis were also other morphologic features.

M.B.P.224

THE INTERACTION OF HIV AND HEPATITIS B VACCINATION IN A COHORT OF HOMOSEXUAL AND BISEXUAL MEN

Buchbinder, Susan P.*; Hessol, N.*; Lifson, A.*; O'Malley, P.*; Barnhart, L.*; Rutherford G.*; Hadler, S.**.
*Dept.of Public Health,San Francisco,CA;**Viral Diseases,CDC,Atlanta,GA,USA.

Objective. To evaluate the effect of HIV infection on efficacy of the hepatitis B vaccine (HBV) and the effect of HBV on HIV disease progression.

Methods. 359 homosexual/bisexual men participated in a randomized controlled trial of HBV from 1980-1981. We began follow-up studies of HIV-related diseases in 1983. We compared peak hepatitis B surface antibody (HBsAb) response, development of immunity (defined as HBsAb SRU >10) and rate of loss of immunity in 2 groups: men who were HIV seropositive (SP) prior to first dose of HBV (N=26) and men who remained HIV seronegative (SN) throughout follow-up (N=126). We also compared the prevalence of AIDS and ARC in SP versus HIV-infected men receiving placebo (N=25).

Results. SP were less likely than SN to develop immunity (65% vs 90%, p=0.01). Of men achieving immunity, SP had significantly lower peak responses and were more likely to lose immunity than SN (p<0.01.) Kaplan-Meier analysis examining loss of immunity from time of first vaccine dose showed 41% of SP (95% CI=17%-65%) lost immunity by 20 months versus 56% of SN (95% CI=45%-67%) at 72 months. There was no difference in the prevalence of AIDS and ARC between SP versus HIV-infected men receiving placebo.

Conclusion. Plasma derived hepatitis B vaccine is significantly less efficacious in HIV seropositive than seronegative men. A majority of seronegatives also lose antibody over time, indicating the need for studies of the efficacy of booster doses. The hepatitis B vaccine does not cause acceleration of HIV-related disease.

M.B.P.225

TOXOPLASMOSE OCULAIRE AU COURS DU SIDA

Pégueux, S.*; Zazoun, L.**; Matheron, Sophie*; de Truchis,P.* Coulaud, J.P.*; Saimot, A.G.*.
* Hôpital Bichat-Claude Bernard, ** Hôpital Pitié-Salpêtrière, Paris, France.

Objectifs. Décrire les caractéristiques de la toxoplasmose oculaire (TO) observée chez les patients (Pts) HIV +.

Méthodes. De 1/84 à 12/88 un examen du Fond d'Oeil (FO) a été fait par les mêmes ophtalmologues chez les Pts HIV ayant des troubles visuels et/ou systématiquement (2 FO/an chez les asymptomatiques (CDC II), 4 FO/an (CDC III et IVC2), 1 FO/mois/Pts SIDA). Les critères de TO étaient : vitré clair, prédominance de l'atteinte du pôle postérieur, foyer en règle unique/bords flous, taille variable ± plages de nécrose, extension en l'absence de traitement(Tt), cicatrisation sous Tt spécifique.

Résultats. Dix cas de TO (8 européens, 2 africaines ; HIV1 : 9, HIV2 : 1 ; $CD4 \leq 120$) ont été observés : 1984-86 : aucune TO/49 nouveaux cas de toxoplasmose (TOX) ; 1987 : 3 TO/20 TOX ; 1988 : 7 TO/33 TOX. Sept cas ont été révélés par une baisse de l'acuité visuelle, 3 étaient asymptomatiques. Une autre IO avait précédé la TO chez 4 Pts (2,6,7,22 mois). Chez 6 Pts la TO a été la 1ère IO. Deux Pts étaient sous AZT. Cinq Pts ont une TOX cérébrale associée (4 simultanées, 1 découverte 2 mois après la TO). Cinq n'ont pas de TOX cérébrale détectable (clinique/scanner). La cicatrisation a été obtenue 10 fois/10 sous pyrimethamine (P)/+ sulfadiazine (8 Pts) ou P/clindamycine (2 Pts).

Conclusion. 1) Dix cas de TO ont été observés en 1987 et 1988 - 2) La TO peut être la 1ère IO - 3) La TO est associée 5 fois/10 à une TOX cérébrale détectable - 4) Le traitement permet la cicatrisation des lésions - 5) La prophylaxie des rechutes est identique à celle des TOX cérébrales.

M.B.P.226

TOXOPLASMOSE OCULAIRE AU COURS DU SIDA

Chakroun, Mohamed*; Meyohas, M.C.***; Pelosse, B.***; Zazoun, L.****; Vacherot, B.** et Leport, C.*.
* Hôpital Claude Bernard, ** Hôpital Bichat, *** Hôpital Saint-Antoine, **** Hôpital Pitié-Salpêtrière ,Paris, France.

Objectif. Préciser Les signes cliniques et ophtalmologiques (OPH) de la toxoplasmose oculaire (TO), son évolution sous traitement (trt) et ses relations avec la survenue d'une toxoplasmose cérébrale (TC).

Méthodes. Etude rétrospective des cas de TO chez des patients (pts) atteints de SIDA, depuis 1983 dans 2 services de maladies infectieuses.

Résultats. Il s'agissait de 9 hommes, 8 homosexuels, vus en 1985 (n=1), 1986 (n=1) et 1988 (n=7). 7/9 pts avaient une acuité visuelle, ≤5/10, et 3/9 pts une fièvre. Tous avaient une choriorétinite du pôle postérieur, associée à une hyalite. Chez 7/7 pts, l'angiographie confirmait le foyer choriorétinien et la ponction de la chambre antérieure ne montrait pas de synthèse locale d'anticorps. Le trt a été débuté 12 j (0-29) après les 1ers signes de la TO. Les pts ont reçu clindamycine, 1,2-4,8 g/j (n=5), sulfadiazine, 6g/j (n=3), ou spiramycine, 3 g/j (n=1), associées à pyriméthamine 50-100 mg/j, pendant 45 j, poursuivies à doses réduites chez 6 survivants. La TO a cicatrisé chez les 9 pts, après 37 j (21-90). Aucune rechute n'a été notée après 5,5 mois (1,5-9). Une TC est survenue chez 7/9 (78%) pts. 4 fois, TC et TO étaient reconnues simultanément et l'évolution de la TC était favorable ; mais 3 fois la TC se révélait 9, 38 et 50 j après le début du trt de la TO, et son évolution n'était pas évaluable.

Conclusion. La TO est devenue plus fréquente au cours du SIDA. Son diagnostic repose sur l'examen OPH. Une TC associée doit être recherchée.

M.B.P.227

OCULAR INVOLVEMENT IN CHILDREN WITH HIV INFECTION

Blini,M; Bertoni,G; Chiamo,M; Massironi,E**; Plebani,A; D'Arminio Monforte,A°°;*
**II Ophthalm. Clin., **IV-°I Paediat. Clin., °°Infect. Dis. Clin. University of Milan, Milan, Italy.*

Objective. Evaluation of ocular involvement in children with HIV infection in respect to adult AIDS.

Methods. The AA report on ophthalmological findings in 57 HIV seropositive children. According to the definition proposed by CDC (april 1987) seropositive infants were 15 in P-0 class, 16 in P-1 class and 18 in P-2 class. 7 patients became negatives and 3 died. Ocular examination, at the start and every 3 months, included: ocular reflexes and motility, fundus and EVR in pathologic cases only.

Results. Ocular signs observed in 13 children (22.8%) were mainly represented by optic nerve involvement (optic disc pallor and subatrophy, papilledema). CMV retinitis in occured in 2 cases (11% vs > 50% in adults). Retinal microangiopathy was never observed in HIV seropositive children.

Conclusions. Paediatric AIDS is believed as a new inborn disease with very different clinical and biologic characteristics in respect to adult AIDS as well as from the ophthalmological point of view.

M.B.P.228

VITROUS FLUOROPHOTOMETRY IN HIV INFECTION

Mauro Collini*, A.Baldi*, P.Costigliola**, E.Ricchi**, F.Chiodo**, R.Caramazza*
*Cattedra Clinica Oculistica II - **Istituto Malattie Infettive; Universita' di Bologna, Bologna, ITALY.

Objective. To evaluate the ability of vitreous fluorophotometry to detect early lesion of vascular retinopathy during HIV infection.

Methods and Results. We have studied 18 subjects with HIV infection (5 AIDS with G.I. and 5 ARC); all patients underwent an eye examination including slit lamp biomicroscopy, indirect ophtalmoscopy, fluorangiography and vitreous fluorophotometry. In spite of the fundus normality the vitreous fluorophotometry readings were constantly above normal, showing average fluorescein values of 3.6 , 3.3 and 4.87 g/ml respectively in the anterior, middle and posterior vitreous.

Conclusion. Etiology and pathogenesis are unclear but the role of circulating immune complexes deposition, increase blood viscosity and HIV direct effect on vascular endothelium tissue, are discussed. The fluorescein angiographic documentation of mycroaneurisms, telangiectasias, focal areas of non perfusion and capillary loss in patients with HIV infection provides a pattern of microvascular retinopathy very similar to the diabetic one. Nevertheless fluorescein angiography is not a quantitative technique and shows low sensitivity in assessing fluorescein permeability. The fluorophotometry permits on the contrary a qualitative evaluation of the alterations of blood barrier which can be discovered by vitreous fluorophotometry before any clinical and fluorangiographic detectable lesion.

M.B.P.229

RETINAL MANIFESTATIONS IN HIV PATIENTS

Minnella A.**, Pizzigallo E.*, Federico G.*, Antinori Andrea*, Tamburrini E.*, Ortona L.*
*Clin. Malattie Infettive, **Clin. Oculistica-Università Cattolica-Rome-Italy.

Objective: To evaluate the occurrence of fundus ocular manifestations in HIV patients; to assess therapeutic problems in CMV retinitis.
Methods: we studied 66 HIV-infected patients (42 AIDS, 10 AIDS-related complex, 14 without symptoms, anti-HIV+), 16 homo/bisexuals (24,2%), 44 i.v. drug abusers (66,7%), 4 heterosexuals (6,1%) and 2 haemophiliacs (3,0). They prospectively underwent a complete ophthalmologic examination, including indirect ophthalmoscopy, color photographs and eventually fluorescein angiography.

Results:	normal	cotton-wool spots (%)	CMV retinitis (%)	acute retinal necrosis syndrome (%)
AIDS (42)	21 (50.0)	18 (42.8)	4 (9.5)	1 (2.4)
ARC (10)	9 (90.0)	1 (10.0)	0	0
anti HIV+ (14)	14 (100)	0	0	0

CMV retinitis, treated with i.v. ganciclovir showed stabilization or partial improvement; all cases relapsed within two to six weeks of discontinuing therapy.
Conclusion: Cotton-wool spots are the main retinal changes; they seem to be related to the progression of HIV infection toward AIDS and unrelated to clinical manifestations. A complete opthalmological examination is needed in HIV pts for early diagnosis of CMV retinitis that could benefit of an early treatment. CMV retinitis relapses at the discontinuing therapy and long-term treatment would be probably necessary.

M.B.P.230

A STUDY OF RETINAL COTTON WOOL SPOTS IN HIV PATIENTS

Minnella A.**, Antinori A.*, Tamburrini Enrica*, Bagolini B.**
* Istituto Clinica Malattie Infettive, ** Istituto Clinica Oculistica-Università Cattolica - Roma - Italy.

Objective: To investigate the characteristics of cotton wool spots (CWS) in HIV patients, compared with other systemic causes of CWS.
Methods: 66 HIV patients (42 AIDS, 14 ARC, 10 asymptomatics) were examined for ocular fundus changes, and, if CWS were detected, fundus color slides were taken and then projected into a grid sheet in order to draw the location and size of CWS; then we made a comparison with the photographs of 60 patients affected by hypertension, diabetes, central retinal vein occlusion with CWS.
Results: CWS were discovered in 42.8% of AIDS, 10% of ARC and 0% of asymptomatic HIV patients, and were present predominantly along the vascular arcades (superficial peripapillary capillary network) with a predilection for the posterior pole.
Conclusions: Compared to other non AIDS systemic abnormalities, CWS in HIV patients are similar in appearance and location, although, either single or multiple, they are more demarcated, never tend to be confluent and last longer. They are easily differentiated from early foci of CMV retinitis and no strong correlation seems to be between these two entities.

M.B.P.231

THE LIVER IN THE AIDS: A CLINICAL AND HISTOLOGIC STUDY

Bonfim de Lima, Dirce; Costa, R.; Silva, O.; Jurado, E.; Moreira, P.
Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brasil.

From March 1985 to March 1988, 30 patients with AIDS were submitted to liver biopsy at the Infectious Disease Unit. They presented unexplained fever and/or hepatomegaly and/or impairment of liver function. The abnormal results of serum biochemical liver tests were alkaline phosphatase activities up to twice the normal value in 13 cases (43%) and SGOT/SGPT levels higher than three times the normal ones.

From the 32 biopsies (two patients had double ones) performed, 16(50%) were done through laparoscopy, 14(43.75%) by "blind" percutaneous puncture and two patients were submitted to autopsy.

The macroscopy showed liver enlargement in 15 cases (83%), congestion in 5 cases (27.7%) and splenomegaly in 8(44.4%).

The histopathology showed nonspecific hepatitis in 19 specimens (59.4%), fatty infiltration in 12(39%), aneosinophilic granulomas of unknown etiology in 5(15.3%), active chronic hepatitis in 2 (6.3%), cryptococcosis in 2(6.3%), cytomegalic inclusion body in 1 (3%), histoplasmosis in 1 (3%) and tuberculosis in 1 (3%).

The hepatic fragments were sent for culture of mycobacteria, common bacteria and fungi, but only one gave growth of Mycobacterium tuberculosis and the other ones were negative.

Hepatic involvement in AIDS is often nonspecific and deserve better appraisement.

M.B.P.232

GASTROINTESTINAL LYMPHOID HYPERPLASIA IN AIDS

Scevola Daniel*; Zambelli A.*; Paulli M.*, Fiocca R.**
Institute of Infectious Diseases* and Institute of Pathology** Univ. Pavia, ITALY.

Objective. To demonstrate that disorders of gastrointestinal lymphatics may contribute to lymphocytopenia in AIDS.
Methods. We examined by fiberoptic endoscopy, biopsy and histology GI mucosa of AIDS patients with clinical and microbiological picture of enteropathy to identify lymphoid hyperplasia and dilatation of lymph vessels of the mucosa and submucosa, conditions associated with lymphocytopenia and lymphocyte loss via GI tract.
Results. T4 lymphopenia is a constant feature of late stages of HIV infection, that well correlates with presence of lymphoid hyperplasia (LH) of GI mucosa and signs of enteropathy (malabsorption, diarrhea, abdominal complaints, protein loss, endoluminal parasitic infections). At endoscopy the key finding of LH are multiple, 1-to 2 mm, pale areas or tiny mucosal excrescences with nodular appearance which histologically show lymphoid follicles, lymphangiectasy and villous atrophy.
Discussion. LH of GI tract in AIDS patients may be a contributing factor of lymphocytopenia, condition that can be due to the loss of the lyphocyte-rich lymph fluid into GI secondary to the disorders of GI lymphatic channels.

M.B.P.233

PANCREATITIS ASSOCIATED WITH HIV INFECTION

Dowell, Scott*; Holt, E.*; and Murphy, F. K.**
*The Johns Hopkins Medical Institutions, Baltimore, MD,
**U.T. Southwestern Medical School, Dallas, TX, USA.

Objective. To assess the prevalence of and risk factors for pancreatitis among patients followed for HIV infection in an urban infectious disease practice.
Methods. A retrospective study was conducted in patients who had AIDS (105 patients), ARC (46), were seropositive and asymptomatic (39), or who were uninfected but at risk for HIV-1 infection (9). Logistic regression was used to identify infections and medications associated with pancreatitis, as defined by clinical and laboratory criteria.
Results. Twenty-two percent of patients with AIDS, 9% with ARC, 3% of asymptomatic HIV-1 infected patients, and no uninfected patients at risk for HIV-1 developed pancreatitis. Pancreatitis was more likely to have occurred in patients with AIDS than in patients without AIDS ($p = 0.0017$). Additional factors bivariately associated with pancreatitis were biliary tract disease and hypertriglyceridemia, but not level of alcohol use. After matching for these factors and severity of current HIV disease, cryptosporidiosis, IV pentamidine and isoniazid were associated with pancreatitis ($p < 0.05$ for all 3). Significant unadjusted odds ratios were found for cytomegalovirus and cryptococcal infection and use of ketoconazole, but were not confirmed by logistic regression analysis.
Conclusion. These data support earlier reports that pancreatitis is commonly found in patients with AIDS. Cryptosporidiosis and certain drugs may be aggravating cofactors.

M.B.P.234

The value of gastrointestinal endoscopy for strategy and control of therapy in epidemic KS

Plettenberg, Andreas*, A. Stoehr**, F. Begemann**, W. Meigel*
Allg. Krankenhaus St. Georg, *Dermatologie, **I.Med.Klinik, Hamburg, Germany.

Objective: To examine the value of gastrointestinal endoscopy (GIE) in therapy of epidemic Kaposi's sarcoma (KS)
Methods: In a prospective study 20 pat with KS-lesions of the skin were examined by GIE before starting therapy (interferon, zidovudine, chemotherapy). 6/20 pat were controlled by GIE during therapy. In an additional group GIE was performed in 13 HIV-infected pat without skin- KS- lesions (WR V: 5x, WR VI: 8x)
Results: Gastrointestinal KS-lesions could be found in 12/20 pat (60 %) with lesions of the skin. 2/17 (17 %) presented less than 10 skin-lesions. However only in 3/12 pat (25 %) the number of gastrointestinal-lesions surpassed the number of skin-lesions. In 4/8 pat (50 %) where GIE showed no intestinal KS, we saw less than 10 skin-lesions. There was no correlation between the number and size of intestinal and skin-lesions of KS. 6 pat were controlled by GIE during therapy. It was remarkable, that 2/6 pat (33 %) showed progression of the skin-lesions, while gastrointestinal lesions disappeared. On the other hand in one pat with no change in skin-lesions there was a progression of intestinal KS. In the group of 13 pat without skin-KS, who became GIE for other reasons, no case of intestinal lesions was seen.
Conclusion: From these results we can conclude, that there may be a major difference in number and size of KS- lesions of the skin and the upper intestinal tract. GIE examination of pat with KS before and during therapy is essentiell in planing and evaluating the success of therapy.

M.B.P.235 ACUTE PANCREATITIS IN PATIENTS WITH AIDS

Bernal, Antonio; del Junco, G; Pies, D; Steed, E; Conklin, R; Conklin, J.
Park Plaza Hospital, Houston, Texas,U. S. A.

OBJECTIVE. To describe 23 cases of acute pancreatitis in patients with AIDS.
METHODS. 23 patients with clinical, laboratory or CT evidence of acute pancreatitis were reviewed retrospectively. Four cases were diagnosed at surgery.
RESULTS. The patients represent 3.7% of 620 cases of AIDS seen at the hospital between 1984-1988. All patients were male homosexuals ranging in age from 26-61 with a mean of 37 years. 20 patients had received multiple drugs to include pentamidine (14), DHPG (9), penicillamine, amphotericin, fansidar and AZT. Four patients were chronic alcoholics. One had hyperlipidemia, one had a large cell lymphoma without pancreatic involvement, and one had no known predisposing factors. WBC ranged from 900 to 7000 with a mean of 3270. Amylase ranged from 86-896, lipase 39-7772. CT scan of the abdomen was positive in only 3 of 17 cases initially, but follow up CT scans helped in management. The clinical spectrum varied from moderate recurring abdominal pains with persistent hyperamylasemia or hyperlipasemia and a benign course, to a fulminant attack, at times mimicking a perforated viscus with a high immediate mortality (4 of 6).
CONCLUSIONS. 1). Clinically manifest acute pancreatitis occurs in at least 3.7% of hospital admissions for AIDS.
2) Clinical presentation varies, ranging from moderate chronic abdominal pain with a benign course, to a fulminant acute abdomen with high mortality.
3) 96% of patients had received potentially toxic drugs.
4) CT scan of the abdomen was most beneficial in follow up of fulminant cases, rather than for early diagnosis.
5) Clinicians should be aware of the possibility of pancreatitis in AIDS. Routine amylase and lipase is recommended.
6) The etiology of acute pancreatitis in AIDS requires further study.

M.B.P.236 HIV ENTEROPATHY IN LUSAKA, ZAMBIA: A CLINICAL, MICROBIOLOGICAL, HISTOLOGICAL AND FUNCTIONAL STUDY

*Conlon, Christopher, **Lucas SB, +Luo NP, ++Moody AH and *Pinching AJ
*St. Mary's Hospital Medical School, London, UK,**Wolfson Tropical Pathology Unit, London School of Hygiene and Tropical Medicine, London, UK, ++St. Pancras Hospital for Tropical Diseases, London, UK, +University Teaching Hospital, Lusaka, Zambia.

Objectives: to investigate the pathogenesis of chronic diarrhoea in HIV positive subjects in Lusaka
Methods: 44 seropositive patients with and 19 without chronic diarrhoea were compared to 36 seronegative controls with abdominal pain but no diarrhoea. Clinical and endoscopic examinations were done, stools examined by microscopy and culture and duodenal biopsies examined histologically. Some patients underwent tests of small bowel function (1-hour xylose tests and/or lactulose/mannitol permeability tests) and non-invasive pancreatic function tests (PAS/PABA excretion).
Results: 55% of patients with chronic diarrhoea had enteric pathogens compared to 10% of seropositives without diarrhoea and 3% of controls. None of the seronegative controls had abnormal duodenal biopsies while 33% of the seropositive patients had moderate to severe villous blunting, with greater inflammation in the patients with parasites. HIV-positive patients had evidence of small bowel dysfunction but this did not correlate with histology
Conclusions: Just over half of the Lusaka patients with HIV enteropathy have an identifiable pathogen, while some others have structural and functional evidence of small bowel damage. Chronic diarrhoea may result from direct damage to the gut from HIV with, or without, the addition of enteric pathogens. The direct effects of HIV need further study.

M.B.P.237 ACUTE DIARRHEA IN HIV + PATIENTS ASSOCIATED WITH *B. HOMINIS*.

Morris, Scott K.; Shaunak, S.; Estevez, E. G.; Bartlett, J. A. and Waskin, H.
Duke University Medical Center, Durham, NC. USA.

Objective: The association of *Blastocystis hominis* (BH) in stool with acute diarrhea is uncertain. During 1987 and 1988, we have seen the emergence of this protozoa in the stool of our HIV positive (+) patients with acute diarrhea. The clinical features of these patients' illnesses have been reviewed.
Methods: A retrospective study of 14 HIV + patients (asymptomatic HIV + =11, ARC=1, AIDS=2) in whom 18 separate episodes of acute diarrhea occurred was undertaken. In every case, >5 BH were seen/hpf on stool microscopy. *Salmonella, Shigella* and *Campylobacter* were not found on culture. AFB were not seen and *Cryptosporidium* was seen in 1 case.
Results: Twelve patients were homosexual and 2 were bisexual. Their major symptoms were malaise, abdominal pain and watery diarrhea for a mean period of 23 days (range 3-75d). CD4 lymphocyte counts (mean 280/mm^3, range 53-601) did not correlate with the duration or the severity of symptoms.
Stool microscopy showed:

BH only =6
BH + *E. nana* =3
BH + *E. nana* + *E. hartmannii*=1
BH + *E. nana* + *E. hartmannii* + *D. fragilis* =1
BH + E. histolytica =4
BH + Giardia lamblia =1
BH + cryptosporidium =1
BH + CMV colitis =1

In 6 episodes *B. hominis* was the only organism identified; 5 of these episodes occurred in the asymptomatic HIV + group. Symptoms in 17 of the 18 episodes resolved within 14 days of starting metronidazole in a dose ranging from 250-750 mg x 3/d for 5-10 days.
Conclusion: The presence of *B. hominis* in the stool of HIV + patients with acute diarrhea should not exclude a search for other causes. In the absence of any such cause, metronidazole can be effective in resolving symptoms. A prospective study is now needed to further examine the relationship between *B. hominis* and acute diarrhea.

M.B.P.238 ENDOLIMAX NANA AND BLASTOCYSTIS HOMINIS INFECTIONS IN HIV-1 SEROPOSITIVE PATIENTS.

Sanusi,Sahid*; Olopoenia,L.*; Grigsby, M.*; Barnes,S.*; Afessa,B.*; and Frederick,W.*
* Howard University Hospital, Washington, DC. U.S.A

Objective. To determine the prevalence of enteric protozoa in symptomatic and asymptomatic adult HIV-1 seropositive patients. It has been suggested that protozoan parasites may play a role in the progression of HIV-1 infection. Methods. Stools from 64 adult (46 males; 18 females) HIV-1 seropositive patients enrolled in a study of the natural history of AIDS were analysed for the presence of enteric protozoa. The MIF and trichrome staining procedures for protozoa and the modified acid fast Kinyoun stain for Cryptosporidium were performed on freshly collected stool samples preserved in 10% formalin. Results. Mean age of group was 35.4 years. Risk factors for HIV-1 included homosexuality in 32 patients, intravenous drug use (IVDU) in 27 and heterosexual contact in 5. Twenty patients had AIDS, 27 had ARC and 17 had generalized lymphadenopathy (GLN). Twenty-eight (43.8%) patients had diarrhea. Overall 21/64 (32.8%) patients had evidence of enteric protozoa in their stools; 4 symptomatic and 3 asymptomatic AIDS patients, 9 symptomatic and 3 asymptomatic ARC patients and 2 symptomatic GLN patients. Among patients with diarrhea E.nana (12) and B.hominis (6) were the predominant protozoa seen. No cases of cryptosporidium, enteric bacterial or fungal pathogens were isolated Conclusions. No significant differences were noted between homosexual and IVDU patients or between AIDS and ARC patients in the frequency of enteric protozoa seen. Symptomatic ARC patients were found to be infected more frequently with protozoan parasites. E.nana and B.hominis were the most frequent protozoa identified in symptomatic patients and should be considered as additional protozoan pathogens causing diarrhea in symptomatic HIV-1 patients.

M.B.P.239 INVESTIGATION OF HIV POSITIVE PATIENTS WITH GASTROINTESTINAL SYMPTOMATOLOGY

Peters, Barry† Francis, N†* Boylston, A.W†* Harris, J.R.W†** Pinching, A.J† Depts of *Immunology, **Histopath, ***GU Medicine, St. Mary's Hospital, UK.

Objective. To review the clinicopathological findings of all HIV+ve patients presenting with gastrointestinal symptoms resulting in colorectal biopsy.
Methods. 126 patients, 70% with AIDS, presented with symptoms requiring lower bowel endoscopy and biopsy. The presenting symptoms were: diarrhoea 118 patients, lower abdominal pain 34, weight loss 27. Stool microscopy and culture, including virology, were performed.
Results. 41 patients had evidence of a pathogen which could account for their presenting symptoms. Multiple infections were present in 10 cases.

Pathogen	Total Number	Positive Stools	Positive Colorectal Biopsies
Cryptosporidia	16	5	11
Mycobacteria	15	14	10
Cytomegalovirus (CMV)	8	0	6
Salmonella	2	2	0
Campylobacter	2	2	0
Giardia	1	1	0
Kaposi's Sarcoma	4	0	4

One case had ulcerative colitis and 5 cases had intestinal spirochaetosis. The mycobacteria (M) were speciated as M. avium intracellulare (9), M.tuberculosis (3), M.fortuitum (1), unidentified (1).
Conclusion. 1.Rectal biopsy was most valuable for diagnosis of cryptosporidium and CMV and gave earlier results than culture for M(Mycobacteria). 2. 68% did not have an identifiable cause; antibiotic therapy or HIV enteropathy may have been responsible.

M.B.P.240 CANDIDA ESOPHAGITIS (CE) IN PATIENTS INFECTED BY HUMAN IMMUNODEFICIENCY VIRUS (HIV).

B.Clotet,G.Sirera*J.Boix,M.Dominguez,A.Jou,J.Tor,M.Foz.
Infectious Diseases Unit;*Gastroenterology Service,Hospital de Badalona "Germans trias i Pujol",Badalona,Barcelona,Catalonia,Spain.

Objective:To identify the incidence of CE as an opportunistic infection (OI) in our population who fulfill the AIDS criteria.Methods:We have practiced esophageal endoscopy (EE) to all patients admitted that belonged to groups at risk for AIDS.EE was done in the first 72 hours after admission and in spite of absence of symptoms or oral thrush.Patients gave their consent in all but 6 cases.We have studied 85 AIDS patients.Results:Candida esophagitis is present in 58% of cases (48 patients).24% (20 patients) of our AIDS cases have CE as the only OI present.In 80% (20 patients) of Pneumocystis carinii pneumonia(PCP) there is associated a CE process.In 8 cases CE was present alone as a OI but CE was associated with right-sided endocarditis,pneumonia or pulmonary tuberculosis in these cases.The therapeutic approach has been always ketoconazole 100 mg twice daily for 10 days.Discussion:In some patients at risk for AIDS CE is found as the only OI and in this subgroup some (8 cases) have a long follow-up (40 months) without presenting any other complication. Therapy is always succesful with oral ketoconazole assessed by disappearence of symptoms when manifested in CE.In some patients an EE repeated at a 10-day interval has corroborated the clinical response to ketoconazol.Prognostic significance may be given by the concomitant presence of other OI,or HIV antigenemia.If all patients at risk for AIDS were endoscoped we would find more unsuspected cases (asymptomatic ones) of CE.

M.B.P.241 GASTROINTESTINAL (GI) STRUCTURE AND MUCOSAL FUNCTION IN HIV POSITIVE PATIENTS.

Church, D., Sutherland, L., Huang, W., Kelly, J., Gill, J.
AIDS Research Interest Group, University of Calgary, Calgary, Alberta Canada.

Unexplained weight loss and diarrhoea are relatively frequent in HIV infected patients. We have investigated 19 patients in whom no gastrointestinal pathogens could be identified to see if functional or structural changes in the small intestine could account for their weight loss and diarrhea. Nineteen patients (17 males, 2 females) were investigated by endoscopy. Biochemical testing demonstrated normal red blood cell folate and vitamin B12 levels in all patients. However, serum ferritin levels were increased in 12 patients. D-xylose absorption tests were abnormally low in 8/13 cases. Duodenal aspirates were negative for giardia lamblia. Light microscopy failed to show any structural abnormality in both upper and lower bowel biopsies. In contrast ultrastructural changes were demonstrated in all patients at the epithelial stromal junction of intestinal crypts with scattered degenerative or necrotic fibroblasts interspersed with reactive hyperplastic fibroblastic cells which appeared to lay down excessive collagen beneath the epithelial cells. These findings suggest that certain Biochemical and ultrastructural abnormalities are common in HIV positive patients even in the absence of infectious pathogens. Defects in carbohydrate absorption and ultrastructural changes may be responsible for some aspects of HIV enteropathy.

M.B.P.242 RELATION BETWEEN HIV INFECTION AND Non-A, Non-B HEPATITIS.

Castillo, Inmaculada; Martinez, MG.; Garcia-Reinoso, C.; Porres, JC. and Carreño, V. Hepatology Unit. Fundación Jiménez Díaz. Madrid (SPAIN).

It has been reported that hepatitis B virus chronic carriers with anti-HIV positive have less hepatic injury than those without HIV infection. However, it is still unknown the influence of HIV among patients with chronic Non-A, Non-B (NANB) hepatitis. Thus, we have studied the hepatic injury degree in chronic NANB hepatitis with or without anti-HIV.

There were included 13 patients with chronic NANB hepatitis. Eigth of them were anti-HIV negative (5 with a posttransfusional history and 3 drug abusers), and the other 5 were asymptomatic HIV carriers (all drug abusers). The presence of anti-HIV was confirmed by Western-blot.

The levels of albumin were higher among those NANB patients anti-HIV negative (4.3 ± 1.1 g/dl) than in the HIV-seropositive ones (3.6 ± 0.2). On the other hand, the transaminases were increased in the anti-HIV positive subjects when comparing with the anti-HIV negative cases (108.7 ± 105.7 vs 96 ± 79.4 IU/l, respectively), although there were not statistical differences. Finally, the histological diagnosis was very similar between both group of patients (anti-HIV +: 80% of chronic active hepatitis (CAH), 20% of chronic persistent hepatitis (CPH); anti-HIV -: 75% CAH, 12.5 CPH and 12.5% cirrhosis).

In conclusion, patients with chronic NANB hepatitis and HIV infection present higher levels of transaminases. This suggests that the hepatitis NANB virus could have a direct cytopathic effect and that the immune response is not involved in the hepatic injury. However, as the causal agent of the hepatitis NANB is not yet identified, this should be proven in future researchs.

M.B.P.243 HEMOPHAGOCYTIC HISTIOCYTOSIS IN THE LIVER OF AN HIV-INFECTED FORMER DRUG USER

Novick, David M.*; Tempesta, R. *; and Stenger, R.J.**
*Beth Israel Medical Center, New York, N.Y., U.S.A.; **Nassau County Medical Center, East Meadow, New York, N.Y., U.S.A.

Objective. To report a case of hemophagocytic histiocytosis in the liver of an HIV-infected former IV drug user.
Methods. Clinical data over 23 months and two liver biopsies, including one studied by electron microscopy, were reviewed.
Results. A 32 year old former IV drug-abusing male had HIV antibody by ELISA and Western blot. Alanine aminotranserase (ALT) was initially 83 U/L and increased over six months to 458 U/L, at which time the first liver biopsy was performed. Fatigue and abdominal pain were correlated with increased ALT levels. During the next 8 months, ALT ranged from 237-316 and symptoms improved. On the biopsies liver architecture is preserved, but the portal tracts display mild to moderate fibrosis, focal mononuclear infiltration, and inconstant ductular proliferation. The parenchyma is intact, except for rare necrotic cells. Along the sinusoids are clusters of iron-positive phagocytes and prominant Kupffer cells exhibiting erythrophagocytosis, and in Disse's space there is increased collagen. A few scattered lipid granulomas appear near central veins. Serum HBsAg is negative.
Conclusion. Lacking evidence for other infections previously associated with hemophagocytic histiocytosis, we suggest that HIV may rarely cause the syndrome, which may be associated with manifestations of liver dysfunction. Definitive exclusion of other causes of erythrophagocytosis is not possible, however.

M.B.P.244 ULCERATING PHARYNGO-OESOPHAGEAL LEUKOPLAKIA IN ADVANCED HIV DISEASE.

Kitchen Valerie, Helbert M, Francis N, Logan R, Lewis F*, Pinching A et al.
St Mary's Hospital, London, United Kingdom,*University of Leeds, United Kingdom.

Objective: To characterise the cause of oesophageal ulceration in advanced HIV disease in the absence of infection with CMV or HSV.

Methods: Endoscopy and biopsy was performed on 5 homosexual men presenting with severe dysphagia. Three HIV seropositive men with dyspepsia were used as controls.

Results: Endoscopy revealed large undermined ulcers (>0.5 cm in diameter) in the pharynx and/or oesophagus in the 5 patients with dysphagia, and was macroscopically normal in the 3 controls. Subsequent histological examination of biopsies from the ulcerated areas showed features of viral leukoplakia in all cases; koilocytosis/multinucleation (5), parakeratosis (3), individual cell keratinization (3), and epidermal thickening/hyperplasia (2). There were no histological features of HSV infection in any of the cases, and evidence of candidal infection was seen in only 1 of the 5. CMV was not detected in any of the cases by immunocytochemistry or DNA in situ hybridization. Material from 4 of the 5 cases and 3 HIV seropositive controls was available for DNA in situ hybridization for EBV and HPV. EBV DNA was detected in 3 of the 4 cases and none of the controls. HPV DNA was detected in 3 of the 4 cases and 2 of the 3 controls.

Conclusion: A lesion histologically similar to Oral Hairy Leukoplakia can occur in the pharynx and oesophagus in advanced HIV infection where it may cause significant ulceration. EBV may be causally related to the leukoplakia seen in these cases.

M.B.P.245 SPONTANEOUS RESOLUTION OF CANDIDA ESOPHAGITIS(CE)IN A SEROCONVERTING PATIENT FOR HIV ANTIBODIES

B.Clotet,G.Sirera,*J.Boix,A.Jou,**A.Ribera,C.Tural,M.Dominguez,J.Tor,M.Foz.
Infectious Diseases Unit;*Gastroenterology Service;**Blood Bank Unit.
Hospital de Badalona "Germans Trias i Pujol",Barcelona,Catalonia,Spain.

Objective:To report a case of CE in a seroconverting patient and to discuss whether CE in HIV seropositive patients should always be considered a criterion for AIDS.Material:A 22 year-old white man admitted because of a mononucleosis-like syndrome.He was drug addict since the last 6 months.
Results:The endoscopy and esophageal biopsy demonstrated CE.

	EIA screening	p24	gp 41	HIV Ag	WB
April 20,1988	-	-	-	+	Not Done
May 10,1988	cut off	-	+	+	-
May 20,1988	+	-	+	-	+

EIA:(Behring);p24;gp41(EIA env/core);HIV-Ag(Abbott).
An esophagic endoscopy performed 15 days later demonstrated spontaneous resolution without having received any antifungal therapy.Discussion:In view of our findings we suggest that CE should be considered a criterion for AIDS(at least for informing the patient that is suffering an AIDS)when there is associated another opportunistic infection or when this appear subsequently in a short period of time(less than 4 months),when the patient has a persistent low T4 count(250xmm3)over a 4-month period or when there is HIV antigenemia (excluding the seroconverting patients).All other cases should be followed closely to understand better the prognostic significance of CE.In our experience HIV seropositive patients not fulfilling the criteria commented above have been followed for long periods(45 months)without developing other opportunistic infections.

M.B.P.246 DETECTION OF HEPATITIS B VIRUS DNA IN PERIPHERAL BLOOD MONONUCLEAR CELLS FROM ASYMPTOMATIC ANTI-HIV CARRIERS

F. J. Bartolomé, Inmaculada Castillo, G. Moraleda, M. G. Martinez, J. C. Porres, V. Carreno, V. Hepatology Unit, Fundacion Jiménez Diaz, Madrid, Spain.

It has been suggested that hepatitis B virus (HBV) could act as a co-factor in the development of AIDS in anti-HIV positive patients. Also, HBV-DNA has been detected in peripheral blood mononuclear cells (PBMC) from a high percentage of patients with AIDS or ARC. The aim of this study was to determine the presence of HBV-DNA and HIV-DNA in PBMC from symptomless anti-HIV carriers.
PBMC (2 x 10^7 cells) were obtained from 23 symptomless anti-HIV carriers (16 of them were positive to the hepatitis B virus surface antigen, HBsAg, and 7 negative to HBsAg), and from 50 anti-HIV negative patients (40 with HBsAg and 10 without this marker). Anti-HIV was detected by EIA and confirmed by Western Blot. The HBsAg test was performed by RIA. HBV-DNA and HIV-DNA were detected by dot-blot hybridization in total extracted cellular DNA from PBMC.
The results are summarized in this table:

	Anti-HIV+ N = 23		Anti-HIV- N = 50	
	HBsAG+ N = 16	HBsAg- N = 7	HBsAg+ N = 40	HBsAg- N = 10
PBMC HBV-DNA+	7 (44%)	0	17 (43%)	0

HBV-DNA was found in a similar percentage in PBMC from anti-HIV positive and negative patients. No differences were observed in the T4/T8 ratio in HIV-seropositive patients with or without HBV-DNA in their PBMC (1.1 ± 0.37 and 0.9 ± 0.34, respectively). HIV-DNA was detected in 10/23 (43%) of symptomless anti-HBV carriers. HBV-DNA and HIV-DNA were present simultaneously in only 2/23 (7%) of these patients.
In conclusion, the incidence of HBV-DNA in PBMC of anti-HIV positive or negative patients is similar. There is a small percentage of patients with HBV-DNA and HIV-DNA simultaneously in the PBMC.

Manifestations hématologiques
Hematologic

APHTHOUS ULCERATIONS OF THE GASTROINTESTINAL TRACT IN PATIENTS WITH AIDS

Bach, Michael C*; Howell, D.A.*; Valenti, A.J.*; Smith, T.**;Dretler, R.H.***; and Winslow, D.L.****
*Maine Medical Center, Portland, Maine, USA; **Swedish Medical Center, Seattle, Washington, USA; ***Dekalb General Hospital, Decatur, Georgia, USA; ****Medical Center of Delaware, Wilmington, Delaware, USA.

A new syndrome of aphthous ulcerations of the pharynx and esophagus were recently described in three patients with AIDS (Ann Intern Med Aug 15 1988). We now report seven additional cases, including two patients with giant esophageal ulcers and one patient with colonic ulcers associated with gastrointestinal hemorrhage. All these cases responded dramatically to oral corticosteroid therapy. One patient had high titers of immune complexes by Raji cell assay.

These ulcerations may represent the one end of a spectrum of "autoimmune" ulcerations seen commonly in normal patients as recurrent oral aphthous stomatitis. Illustrative photographs will highlight the clinical cases.

M.B.P.248

HAEMATOLOGIC ABNORMALITIES IN HIV INFECTION.

Mancuso,Salvatrice;Accurso V.;Spina M.;Abbadessa V.;Perricone R. and Cajozzo A.
Department of Internal Medicine,Medical School,University of Palermo,Italy.

Objective.To describe the haematologic abnormalities in HIV infection.
Methods.From April 1985 to December 1988, 683 seropositive subjects were observed at the Center for AIDS control in Sicily.Eighty seven per cent of these were intraverous drug abusers. White cell count,granulocytic count,lymphocytic count,platelet count and red cell count were performed on all patients. In some patients we studied the periferic blood cells and bone marrow morphological characteristics.
Results.The most important haematologic abnormality is represented by thrombocytcpenia.In the group studied its frequency is of 13 per cent.We have found thrombocytopenia expecially at the early stages of disease,while other cytopenias,as anaemia and granulocytopenia,have been observed at the ARC or AIDS stages. Morphological alterations of the granulocytes, as Peulger-like anomaly,although non characteristic,were frequent in AIDS patients. Bone marrow morphological characteristics in 52 patients examined were:increased megakaryocytes,erythroid hypoplasia and megaloblastic changes.
Conclusion.HIV itself and/or other factors such as infections,malnutrition and drugs may affect haematologic parameters.
Various alteretions appear at different stages of the disease.These findings are very important for the choice therapy.

M.B.P.249

MICROANGIOPATHIE THROMBOTIQUE (MAT) ET INFECTION HIV

Nhuong, M.Aude.*; De Truchis, P.*; Oksenhendler, E.*;
Matheron, Sophie*; Dosquet, P.*; Clauvel, J.P.** ; et coll.
* Hôpital Bichat-Claude Bernard, Paris; **Hôpital Saint-Louis, Paris, France,

Objectifs : Décrire les différents aspects cliniques et biologiques de la MAT au cours de l'infection HIV.
Méthodes : Six patients (pts) (5 hommes : 4 homosexuels, 1 toxicomane ; 1 femme zaïroise) présentant des manifestations rénales et hématologiques liées à une MAT, sont décrits ; le mode de présentation et l'évolution de la MAT sont analysés selon le stade CDC de l'infection HIV.
Résultats : Trois pts avaient un SIDA depuis 10 à 18 mois (IV C1:1 pt ; IV C1,D:2 pts). La MAT était révélée par une thrombopénie et une anémie hémolytique avec schizocytose (Hb:45 à 70 g/L; plaquettes : 5 à 23.10^9 /L). Deux des pts étaient traités pour une infection récente (toxoplasmose, mycobactériose). Chez ces 3 pts, l'évolution a été marquée par l'aggravation des signes hématologiques puis par l'apparition d'une insuffisance rénale (IR); ces 3 pts sont décédés en 3 à 4 mois, malgré les traitements institués pour la MAT.
Les 3 autres pts, à un stade plus précoce de l'infection HIV (III:1pt, IV C2:2pts) présentaient une IR aigue révélatrice de la MAT (histologie rénale:2 pts). La MAT révélait l'infection HIV chez 1 pt. L'atteinte hématologique était constante (Hb:80 à 90 g/L ; plaquettes:5 à 100.10^9 /L). Un pt est décédé d'IR aigue avant traitement. Chez les 2 autres pts - vivants à 6 et 18 mois - la MAT a été régressive en 2 à 5 semaines (hémodialyse initiale chez 1 pt).
Conclusions : 1 - L'infection HIV parait être (directement ou indirectement) l'une des circonstances étiologiques de la MAT. 2 - Chez ces 6 pts, il semble exister 2 tableaux de MAT, qui diffèrent par leur présentation initiale (hématologique ou rénale), l'évolution, et le stade HIV.

M.B.P.250

ETUDE PROSPECTIVE DES ANOMALIES DE LA COAGULATION CHEZ 156 PATIENTS CONSECUTIFS SEROPOSITIFS POUR LE VIH.

TAILLAN,Bruno ; ROUL,C ; FUZIBET,J.G. ; VINTI,H ; PESCE,A ; BAYLE,J ; CASSUTO,J.P. ; DUJARDIN,P.
C.H.R.U. de Nice, FRANCE.

156 patients séropositifs pour le VIH ont bénéficié de 3 groupes de tests explorant leur coagulation :
- tests de dépistage : temps de céphaline activé (TCA), temps de céphaline Kaolin (TCK), test de correction.
- tests de localisation du niveau de l'anomalie.
- tests spécifiques à la recherche d'un anticoagulant circulant (ACC) de type antiprothrombinase (APT) : temps de thromboplastine dilué (TTD), lupus anticoagulation test (LAC stago).

46 patients sur 156 présentaient un TCA allongé : 33 avaient un ACC de type APT. Les 13 autres présentaient un déficit le plus souvent multifactoriel (VIII, IX, XI ou XII). 111 sur 156 avaient un TCA normal. 33 présentaient un ACC de type APT (TTD positif 33 fois, LAC positif 21 fois). Sur ces 33, 21 avaient un syndrome inflammatoire marqué. L'analyse des résultats montre :
- la prévalence des anomalies de la coagulation chez les patients VIH + est de 50,6 %. Il s'agit dans 42,3 % des cas d'un ACC de type APT.
- l'allongement du TCA dépiste ces ACC 1 fois sur 2. Sa normalité ne permet pas d'exclure le diagnostic d'ACC (notamment si syndrome inflammatoire).
- cliniquement, absence de thrombose ou d'hémorragies dans notre série.
- Absence de relation avec le stade évolutif de l'infection par le VIH.
- les ACC s'intègrent probablement dans le cadre des manifestations auto-immunes chez les sujets VIH +.

M.B.P.251

"BONE MARROW IN AIDS PATIENTS".

CASALS, A.; ABELLA, E.*; MILLA, F.*; SIRERA G.; JUNCA, J.*; CLOTET, B.; M. INFECTIOUS DISEASE UNIT, AND HAEMATOLOGY SERVICE. Hospital de BADALONA Germans Trias i Pujol, Badalona, Barcelona, Spain

OBJECTIVE: To report our findings in bone marrow studies in patients fulfilling AIDS criteria.
MATERIAL: Bone marrow aspirates and/or biopsies from 30 patients were reviewed. These bone marrow studies have been performed because of otherwise inexplainable anemia or citopenia in most of cases, and/or in the setting of fever of unknown origin.
RESULTS: Cellularity was normal or slightly increased in 28 out of 30 cases (93%). One patient presented focal hypoplasia associated to the presence of granulomas, and another patient presented a global hypoplasia. Erytroblastic serie showed diserytropoetic features in 40% of cases often consisting in megaloblastic traits. Among white cell precursors we observed bone marrow hypereosinophilia in 7 out of 30 patients (23%), and one case with hyperbasophilia. Megacariocits were usually increased, often in association with peripheric thrombocytopenia. Reticulinic fibrosis was seen in 6 cases (20%). Perivascular plasmocytic infiltration was the most common finding, 20 out of 30 cases (66%). We observed granulomas in 4 patients (13%) due in 2 cases to miliary tuberculosis, and in the rest to asymptomatic visceral leishmaniasis.
Finally, haemophagocytosis was observed in other 2 cases.
CONCLUSIONS: Bone marrow study allowed us to diagnose an infectious disease in 13% of AIDS patients admitted because of fever of unknown origin.
We could also observe 20% of cases presenting fibrosis, a finding rarely described in AIDS.
In our serie, the most frequent finding in AIDS patients is perivascular plasmocytic infiltration and diserytropoesis.

M.B.P.252

CIRCULATING ANTICOAGULANT AND HUMAN IMMUNODEFICIENCY VIRUS INFECTION

Durant, J.*; Bernard, Evelyne* ; Roul C.* ; Carles M.* ; Mondain V.* ; Dellamonica P.*
* University Hospital, Nice, France.

From January to September 1988, we made an inventory of 17 H.I.V. patients (11 males and 6 females) with a circulating anticoagulant (CAC) hospitalized in the Tropical and Infectious Diseases ward (Nice). The H.I.V. infection stages (CDC criteria) were : I (1 patient), III (3), IV (13). The presence of CAC was suspected when the activated partial thromboplastin time (APTT) was prolonged (by more than 7 seconds as compared with that in a control) and not corrected by the addition of normal plasma. The activity of the CAC was : antiprothrombinase (13 patients) (10 stage IV, 3 stage III), antipolymerase (3) (stage IV), heparine-like (1) (stage I). Clinical symptoms related to CAC isolation are rare, and were only reported for 3 of our patients ; 2 mucocutaneous hemorragic syndroms : one stage IV patient with a severe thrombopenia combined with an antiprothrombinase, the other a severe H.I.V. primo-infection with a heparine-like. For the third one (stage IV) : a thrombosis of the central retina artery associated to an antipolymerase. In a retrospective case control study of all the H.I.V. patients (n = 100) hospitalized in the same ward during the same period, we evaluated the prevalence of CAC to be 17 %. By a statistical analysis (XI2 test with adjustment). We found a significant relation to CAC and mycobacterial infection (tuberculosis and atypical) (p .001), but not for Pneumocystosis. In our study, there was no statistical difference after 6 months in the rate of survival between the 2 groups (CAC and no CAC). Only a prospective study would establish the relation between CAC, opportunistic infections and the out come of H.I.V. infection.

M.B.P.253 LUPUS LIKE ANTICOAGULANT AND ANTICARDIOLIPIN ANTIBODIES IN NON HOSPITALIZED HIV INFECTED PATIENTS

Capel, P*.; Clumeck, Nathan**; Feremans, W***.; Gerard, M**; Janssens, A*.; Vandevelve, D***.; Fondu, P*.
Divisions of *Hematology and **Infectious Diseases, St Pierre University Hospital, and ***Division of Internal Medicine, J. Bracops Hospital, Free University of Brussels, Belgium.

LLAC and ACA have been studied in 204 HIV infected patients. None of them presented opportunistic infections at the moment of the investigation. 12% were classified in CDC stage 1, 46% in stage 2, 29% in stage 3, and 13% in stage 4. The LLAC was detected by three tests: APTT, dilute thromboplastin inhibition test, and kaolin clotting time. ACA were determined by Elisa. APTT was positive in 6.3% of the patients, KCT in 5.2%, and DTIT in 18%. ACA were positive in 11.6% (IgG) and 4.5% (IgM). There was some association between abnormal coagulation tests and ACA. The frequency of positivity of the coagulation tests was clearly correlated with the stage of the disease: APTT was prolonged in 0% of stage 1 patients, 3% of stage 2, 9.7% in stage 3 and 16.7% in stage 4. The same relationship was not observed for ACA, which were positive in 12% of stage 1 patients, 10.1% of stage 2, 24.4% of stage 3 and 16.7% of stage 4.
We conclude that : 1) LLAC and ACA are present in a relatively low proportion of HIV infected patients who do not present opportunistic infections; 2) there is a relationship between the frequency of positivity of these tests and the stage of the disease, particularly for the coagulation tests.

M.B.P.255 ABDOMINAL LYMPHADENOPATHY IN 200 HIV POSITIVE PATIENTS. ULTRASOUND AND CLINICAL STUDY.

Anne Geoffray, J.P. Cassuto, P. Dujardin, A. Coussement.
Hôpital de Cimiez, Nice, France.

During a 6 months period, 200 HIV positive patients had abdominal ultrasound. There were 148 stage 1-2, 23 ARC syndrome, 29 AIDS. Adenopathy was found in 114 patients. This adenopathy was celiac in the majority of cases (80%) or within hepatic hilum (36%), or lomboaortic (23%). The size was under 3 cm in 76%. Clinical and biological data were rewieved and did not find any particular abnormality either infectious or tumoral. previous hepatitis was the most common finding (55%), even more frequent if more than 2 adenopathies were found (66%). The follow-up of this group of patients (9 to 18 months) did not demonstrate particular abdominal complications. Only 2 patients developped abdominal lymphoma. Although further follow-up is necessary, we believe that the presence of adenopathy less than 3 cm in size at abdominal ultrasound is a common finding in HIV positive patients and does not require further investigation.

M.B.P.257 BONE MARROW FINDINGS IN HIV INFECTED PATIENTS AT GAFFRÉE AND GUINLE UNIVERSITY HOSPITAL - UNIVERSITY OF RIO DE JANEIRO (UNI-RIO).

Brito Lyra, L.C.; Campos de Magalhães, M.; Basílio de Oliveira, C.A.; Eyer-Silva, W.A.; Sion, F.S.; Morais de Sá, Carlos Alberto.
Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO), Brazil.

Objective: To study cytological, histological and microbiological features of bone marrow specimens of 68 HIV infected patients admitted at our institution from 1985 to 1988 and who were classified as group III or group IV according to CDC criteria.
Methods: We studied 68 homosexual/bisexual males 25 to 48 years of age. Twenty-six were classified as group III and 42 as group IV. Bone marrow biopsies and aspirates were obtained from the posterior superior iliac crest. May Grunwald Giemsa, Prussia blue, HE, Wilder and Gomori staining were used.
Results: Cellularity, megakariocytic and lymphoplasmocytic series findings were as follows:

	Nº PATIENTS	CELLULARITY		MEGAKARIOCYTIC		LYMPHOPLASMOCYTIC
		HYPO	HYPER	HYPO	HYPER	HYPER
GROUP III	26	3(11,5%)	4(15,4%)	6(23,0%)	8(30,8%)	9(34,6%)
GROUP IV	42	11(26,2%)	1(2,4%)	7(16,7%)	14(33,3%)	32(76,2%)

Erythrophagocytosis was observed in 2 patients (group IV). Mycobacteria and fungi were not identified. T.gondii infection was demonstrated in 1 patient. Not rarely, megakariocytes were shown to be atypical.
Conclusions: Bone marrow samples should be routinelly obtained from HIV infected patients, specially those who present with peripheral cytopenia and (or) fever of obscure origin. Although some qualitative and quantitative changes were recognized, we could not find any specific alteration.

M.B.P.254 LES LYMPHADENOPATHIES CHRONIQUES SONT-ELLES LE TEMOIN D'UNE AGGRAVATION DE L'IMMUNODEFICIENCE LIEE AU VIH? ETUDE D'UNE COHORTE DE 264 SUJETS SEROPOSITIFS, BORDEAUX, FRANCE : 1985 -1988.

Morlat, Philippe* ; Lacoste, D.* ; Mazllati, P.* ; Dupon, M.* ; Pellegrin, J-L.* et le Groupe d'Epidémiologie Clinique du SIDA en Aquitaine (G.E.C.S.A.)*.
* Centre Hospitalier Régional Universitaire (CHRU), Bordeaux, France.

Objectif. La classification des Centers for Disease Control de l'infection par le VIH distingue les patients asymptomatiques (groupe II) de ceux porteurs de lymphadénopathies chroniques (groupe III). Cette étude recherche si cette distinction correspond à une différence sur le plan du pronostic clinique et biologique.
Méthodes. Pour les sujets classés dans le groupe II ou le groupe III lors de leur inclusion et revus au moins une fois, les données suivantes ont été recueillies : passage dans le groupe IV et au stade SIDA, nombre absolu de lymphocytes T4 par mm^3 de sang (T4). Les probabilités cumulées de passage dans le groupe IV et au stade SIDA sont calculées dans chaque groupe par la méthode de Kaplan-Meier. Le test du logrank est utilisé pour la comparaison de l'évolution des groupes II et III. La comparaison des moyennes (m) du nombre de T4 est effectuée par le test de Student.
Resultats. A l'inclusion, 175 sujets appartenaient au groupe II et 89 au groupe III (données du 10 novembre 1988). Les probabilités cumulées de passer dans le groupe IV après 24 mois de suivi sont de 23,2% pour le groupe II et de 10,5% pour le groupe III ; celles d'aboutir à un SIDA sont respectivement de 12,7% et de 5,9%. Les différences d'évolution entre les groupes II et III ne sont pas statistiquement significatives au seuil de 5%. Le passage du groupe II au groupe IV s'est fait directement dans 85% des cas (n=27). On ne note pas de différence significative entre la moyenne des T4 à l'inclusion des sujets des groupes II (m=540 ; écart-type s=297) et III (m=504 ; s=231). Les moyennes des T4 de 20 patients restés groupe II et de 19 patients restés groupe III ont été comparées : aucune différence significative n'a été mise en évidence, non seulement à l'inclusion mais également après 12 mois. Leur taux moyen de variation a été de -15% pendant cette période.
Conclusion. Aucune différence n'a pu être mise en evidence dans l'évolution clinique et biologique des patients appartenant initialement au groupe II et au groupe III. Les lymphadénopathies ne semblent pas être le témoin d'une aggravation de l'immunodéficience liée au VIH : les sujets appartenant au groupe III ne paraissent pas devoir justifier d'une surveillance et d'une prise en charge thérapeutique plus intenses que les sujets asymptomatiques. Cette constatation doit être confirmée sur une plus longue période d'observation et/ou un plus grand nombre de patients.

M.B.P.256 KIKUCHI'S LYMPHADENITIS IN HIV INFECTION: A CASE REPORT.

Stefano Pileri*, P.Baglioni*, E.Ricchi**, F.Tumietto**, P.Costigliola**, F.Chiodo**.
*Sezione di Emolinfopatologia, Istituto "L.e A. Seragnoli" - **Istituto Malattie Infettive - Universita' di Bologna, Bologna, ITALY.

Objective. The authors report on a case of "histiocytic necrotizing lymphadenitis/Kikuchi's lymphadenitis" (HNL) which occurred in a 17 yr-old female with previous history of drug-addiction.
Case report. The patient seroconverted in 1986 and developed ARC (CDC IVa-WR5a) in July 1988. At that time, she showed generalized lymphadenopathy, lymphopenia (321/mmc) and CD4/CD8 ratio = 0.08. Flow cytometry and double fluorescence displayed a significant expansion of the HLA-D/DR+ subset, which was not due to an absolute increase in activated (CD3+) T-lymphocytes. A Jamshidi needle biopsy revealed moderate myelodisplasia with plasmocytosis. In October 1988, the patient underwent a lymph node biopsy. At histological examination, the normal structure was effaced by multiple foci of infiltration by histiocytes, plasmocytoid T-cells, small lymphocytes, and immunoblasts, with nuclear debris and varying degrees of necrosis. Immunophenotyping showed positivity of: i) histiocytes for lysozyme and CD11b, CD11c, CD14, and Ber-Mac3 molecules; ii) plasmocytoid T-cells for CD45 and CD18; iii) small lymphocytes for CD2, CD3, and CD5 (CD4/CD8 = 1/3). According to morphological and immunohistochemical findings, a diagnosis of Kikuchi's lymphadenitis was made.
Conclusion. To our knowledge, this represents the first reported example of HNL in an HIV-infected patient. It underlines the opportunity of including HIV among the possible etiologic agents of Kikuchi's lymphadenitis.

M.B.P.258 BONE MARROW FINDINGS IN 33 MULTISTAGED HIV-INFECTED PATIENTS

Minoli, Lorenzo*;Malfitano, A.*;Sacchi, P.*;Poma, G.*;Castello, A**; Castelli, G.***.
*Infectious Disease, **Human Pathology,***Hematology Dept. University of Pavia, Pavia, Italy.

Objective. To investigate bone marrow (BM) features in HIV infection in order to any prognostic evaluation.
Methods. 33 HIV-infected pts were studied. They were staged according to CDC criteria: 8 CDC III 10 IVC, 9 IVD, 2 IVB, 4 IVA. Osteomyelobiopsy was carried out by Jamshidi needle. Histopathological work-up was complemented by staining for opportunistic organisms.
Results.

Bone marrow findings	number of patients
Increased cellularity	13/33
Reduced cellularity	4/33
Reduced myelopoiesis	7/33
Dismyelopoiesis	15/33
Increased Megakaryocytes	33/33
Micromegakaryocytes and dystrophic forms	14/33
Lymphocyte infiltrates/aggregates	28/33
Activated macrophages and erythrophagocytosis	18/33
Granulomas (2 cases with giant cells)	3/33

3 cases showed a leukemic pattern.
Conclusion. Above results suggest that BM involvement in HIV infection resembles the hemopoietic dysplasia pattern implying a disorder of stem cell. No sharp correlation between BM abnormalities is identifiable.

Manifestations endocriniennes, cardiaques, rénales, musculo-squelettiques
Endocrine/Cardiac/Kidney/Musculoskeletal

M.B.P.259

ECHOCARDIOGRAPHY IN AIDS PATIENTS. A PROSPECTIVE STUDY IN 24 PATIENTS.

Thyge L. Nielsen*; Videbæk, R.**; Lindvig, K.**; Pedersen, C.*.
* Dept. of Infectious Diseases, ** Dept. of Cardiology, Hvidovre Hospital, University of Copenhagen, Denmark.

Objective: To assess the prevalence and the extent of cardiac abnormalities in AIDS patients with no cardiac history.

Methods: 24 patients with AIDS for 0-485 days (mean 82) were examined. Twentytwo homosexual men, one man with unknown risk factor and a woman infected by transfusion. None were intravenous drug abusers. All patientes were hospitalised: 17 with pneumocystis carinii infection, one with Kaposi's sarcoma and 6 patients with other opportunistic infections incl. CMV and mycobacterial disease. No patients showed signs of clinical cardiac failure. Echocardiographies were performed on an G.E RT 3000 phased array. Examination included standard M-mode + 2D echoes. The echoes were videotaped and reviewed blindly by a cardiac specialist.

Results: 13 cardiac abnormalities were found in 11 patients. Eight patients had slightly to moderat dilatation of the right ventricular chamber 28-36mm (mean 30.1) and 5 patients had a moderat pericardiac exudate. No patients had tachycardia more than corresponding to fever. We found no signs of endocarditis, myocarditis or cardiomyopathia.

Conclusion: Minor cardiac abnormalities seems to be common in AIDS patients with acute infection. In AIDS patients with other riskfactors than intravenous drug abuse they are hardly of clinical importance.

M.B.P.260

NEUROMUSCULAR INVOLVEMENT IN HIV INFECTION.

Graña J., De Luis A., Montalbán J.(*), Fernández J.M.(*), Cervera C.(*), Martínez-Vázquez J.M.
Departments of Internal Medicine and Neurology (*), Hospital Valle de Hebrón, Autonomous University of Barcelona, Barcelona, Spain.

The involvement of the peripheral nervous system (PNS) in patients with infection by the human immunodeficiency virus (HIV) is less well known than that of the central nervous system (CNS). Because of the rarity of these complications, and the interest of their diagnostic and therapeutic aspects, we report 7 patients with HIV infection and abnormalities of the PNS. There were six males and one female, with an age range of 25 to 45 years, with the following conditions: two axonal polyneuropathies , two chronic inflammatory demyelinating polyneuropathies and three polymyosites. At the time of the diagnosis of the PNS involvement, three polyneuropathy patients were stage IV-C1 and one IV-C2, whereas two polymyositis patients were stage II and two were simultaneously diagnosed of tuberculous meningitis and cerebral cryptococcosis. Both patients with axonal polyneuropathy had severe impairement of their general condition with advanced cachexia, which suggests that the neurologic abnormalities could be the result of metabolic and nutritional causes (an accepted pathogenetic mechanism), rather than HIV or other organisms infectious effects. Both demyelinating neuropathy patients did not receive treatement: one patient refused treatement while the other had a rapid and fatal evolution. Of note, the first of these two last patients, improved notoriously without treatment. Only one of the three patients with polymyositis did respond to corticosteroid therapy.
All four polyneuropathy cases had features of both types of neuropathy (axonal and demyelinating). In two patients we observed at different times of their clinical course, transitions from one type of neuropathy to the other and vice versa. We suggest the possibility that these polyneuropathies constitute a single entity, with variable clinical and electrophysiological features.

M.B.P.261

RHEUMATIC SYMPTOMATOLOGY IN PATIENTS INFECTED WITH THE HUMAN IMMUNODEFICIENCY VIRUS (HIV): PREVALENCE AND RELATIONSHIP TO CLINICAL AND LABORATORY VARIABLES

Calabrese, Leonard H.; Myers, A.; Kelley, D.
Cleveland Clinic Foundation, Cleveland, Ohio, USA.

Objective. To define the prevalence of rheumatic symptomatology in a cohort of HIV infected patients as well as its relationships to a variety of clinical and laboratory variables.
Methods. Combined retrospective and prospective analysis of 75 patients followed for a mean of 39 months. Each subject was serially assessed for the development of rheumatic symptomatology during follow-up for HIV infection.
Results. During the follow-up period, 20% developed articular symptoms including four patients with Reiter's or psoriatic arthritis, and 11 patients with new onset oligoarticular or polyarticular arthritis (group A). Fifty-three patients (71%) had no rheumatic symptoms (group B) and 7 patients (9%) had miscellaneous rheumatic symptoms. Group A patients were more likely to be at an advanced clinical stage of HIV infection (i.e. CDC Class IV) than group B ($p<.001$) and had lower hemoglobin, lymphocyte counts, T helper counts and higher ESR values than group B patients ($p<.01$). There was no association between articular disease and any specific risk behavior, other sexually transmitted diseases, infections or malignancies.
Conclusion. Articular disease appears to be relatively common in the setting of HIV infection and correlates with both an advanced state of infection and immunosuppression. These data may partially explain the reported sensitivity of such patients to the adverse effects of immunosuppressive drugs.

M.B.P.262

JOINT, BONE AND MUSCLE LESIONS AND HIV INFECTION.

Rowe, Ian F; Forster, SM; Youle, MS; Hawkins, DA; Lawrence, AG; Seifert, MH and Keat, ACS. Westminster, St Stephen's and St Mary's Hospitals, London, UK.

Rheumatologists at our hospitals have been referred 106 HIV-positive patients since 1985, representing about 4% of the known HIV-positive population in our area. Thirty homosexual men and 2 women presented with acute, aseptic, peripheral, non-erosive, seronegative arthritis (mean, 4 joints affected). Associated features included psoriasis (12 patients), keratoderma blenorrhagica (2), plantar fasciitis (2), urethritis (5), conjunctivitis (4) and uveitis (1). Four of 5 patients tested had HLA-B27. Two with recent diarrhoea had serological evidence of yersinia infection. No microorganisms were identified in joint material except for HIV in 4 patients. At onset of arthritis only 2 had AIDS and 9 were not known to be HIV-positive. Six patients have progressed to AIDS; 4 have died. In 14, including those progressing to AIDS, joint symptoms have been severe, persistent and poorly responsive to NSAIDs. In 5 arthritis has resolved. Other rheumatic lesions seen include infective lesions (7 patients) including one with disseminated histoplasmosis; myalgia/arthralgia (30), with features suggestive of myositis in 12; spinal pain (19); non-inflammatory peripheral arthropathy (6); and soft tissue lesions (12). Rheumatic syndromes in HIV-positive patients are becoming better defined. It is unclear, however, whether HIV itself is a genuine risk factor for some of these, especially aseptic arthritis. The London experience may help to clarify this issue. Pathogenetic mechanisms, including the role of microorganisms and immunodeficiency, require further study.

M.B.P.263

"REDUCED CORTISOL PRODUCTION AND ADRENAL NECROSIS IN PATIENTS WITH AIDS". LEWI, D.S.*; ACCETTURI, C.A.*; SADER, H.*; DIAS, R.S.*; KATER, C.E.*; MOTTA, P.R.*. - * Escola Paulista de Medicina - São Paulo - SP - Brasil.

Objective: To verify adrenocortical reserve and adrenal histopathology in patients with AIDS.

Methods: To verify adrenocortical reserve we measured plasma cortisol levels before and 60 min. after ACTH stimulation (Cortrosyn®, 250 µg IV bolus) in 28 patients with AIDS, 5 with ARC, 10 with chronic non AIDS diseases and 32 normal subjects. Adrenal histopathology was studied in 17 of the 20 patients with AIDS who died. The 95% confidence intervals (CI) for the ACTH-stimulated cortisol levels was established at 18.4 µg/dl.

Results: Five (18%) AIDS patients presented values below the CI: 13,4 ± 1,4 µg/dl. All 5 had massive adrenal necrosis at post-mortem examination (2 had also Citomegalovirus inclusion and 1 *Criptococcus neoformans*). Sensitivity and especificity of the ACTH test compared with the presence or absence of significant necrosis was: 71,4% and 100%, respectively. No patients with ARC or chronic non-AIDS diseases had decreased cortisol response to ACTH stimulation.

Conclusion: Since 18% of patients with AIDS had proven adrenal necrosis with cortisol insufficiency, and might benefit from glucocorticoid replacement therapy, we suggest that a rapid ACTH testing should be performed in every such patient.

M.B.P.264

DIABETES INSIPIDUS AS A COMPLICATION OF CEREBRAL TOXOPLASMOSIS IN AN AIDS PATIENT

Stambuk, Drago; Singh, S.; Gazzard, B.
St. Stephen's Hospital, London, England.

Case presentation. A 52 year old homosexual HIV+ve patient presented with sudden onset headache, dysphasia and blurred vision. He had a low grade pyrexia, right sided upper motor neurone 7th nerve palsy and left sided homonymous hemianopia. Brain CT scan showed multiple localised frontal, occipital, temporal and parietal lobe (left > right) cystic enhancing lesions suggestive of brain toxoplasma infection. He responded very well to treatment with Fansidar (two tablets b.d.), his signs and symptoms disappeared and he was discharged on maintenance Fansidar at a dose of one tablet every alternate day. Six weeks following the beginning of his brain infection he developed polydipsia and polyuria. Diabetes insipidus was confirmed with normal blood glucose, urine osmolalities never exceeding 172 mmol/L and plasma osmolalities of over 300 mmol/L. In spite of clear evidence of hypothalmic dysfunction his anterior pituitary function was normal with a good cortisol response to hypoglycaemia, normal T4 (82 nmol/L), prolactin (574 u/L) and normal responses of TSH, LH and FSH to their respective releasing factors. Treatment with DDAVP resulted in rapid resolution of diabetic symptoms.
Conclusions. Neurogenic diabetes insipidus can follow cerebral toxoplasmosis in AIDS patients.

M.B.P.265 DEFICIENCY OF GLUCOCORTICOIDS IN AIDS

Albrecht Falkenbach, St. Klauke, B. Michels, P. Hunold,
E. Schifferdecker, P.H. Althoff et al.
University Hospital Frankfurt, FRG.

At autopsy of patients with AIDS 88 % of the adrenal and 30 % of the pituitary glands show pathologic changes (GROLL et al.1989). Nevertheless levels of cortisol and results of ACTH stimulation tests are within normal range in most of the patients. Patients with AIDS suffer a continous stress due to psychological reasons, infections, tumors, etc., so that cortisol levels within "normal range" might not be sufficient to meet the enhanced demand.

Beside an iv. ACTH stimulation test (determination of cortisol, -hydroxyprogesterone and aldosterone at 0, 30 and 60 min.) an iv. stimulation test with corticotropin releasing hormone (CRH)(determination of ACTH at 0, 30 and 60 min.) was carried out in 20 patients with AIDS and 2 patients with ARC under resting conditions at 8 o´clock am (two different days).

In 21 patients basal cortisol levels were within "normal range" (7 - 25 ug/dL) with sufficient inrease after ACTH stimulation in 12 patients. In 1 patient cortisol was high (38 ug/dL) without further increase after stimulation. ACTH was high (80 pg/ml) in 10 patients, exceeding 100 pg/ml in 4. 5 of the 12 patients with normal basal ACTH didn´t show an increase after CRH stimulation, as well as 3 of the 10 patients with high basal ACTH levels.

High levels of ACTH under "resting conditions" point at a stressed state of the patients. With maximal ACTH stimulation cortisol levels are slightly sufficient. Inadequate secretion of cortisol must be feared in case of an additional stress, as further enhancement of ACTH secretion is not possible. For that reason we advice an early substitution of cortison in severe stress situations.

M.B.P.266 " GONADAL HORMONE LEVELS AND TESTICULAR HISTOLOGY IN AIDS".

C.ACCETTURI, D.LEVI, E.ARRUDA NETO, A.CEDENHO, J.G. VIEIRA, I.T.N.VERRESCHI. From Escola Paulista de Medicina - Sao Paulo,Brasil.

OBJETIVE To correlate testicular histopathology with gonadal hormone levels in patients with AIDS

METHODS Twelve patients (CDC IV), 11 homosexual males (20-55yrs) with gonads under normal volume (Prader 8-12) and 1 haemophilic prepurbetal boy (10 yrs) were studied. Three plasma sample were collected from each patient at 30 min. interval between 8-10 a.m. in order to measure gonadotropins (LH and FSH) and Testosterone (T), in a pool, by specific RIA methods. The results were compared to sex, age and weight matched controls. Twenty four fragments like biopsies were obtained immediatly after death from the 12 patients, in order to prevent autholisis. The following components were evaluated: germinal epithelium (GE) Sertoli cells (SC), tubular lumen (TL), cellular free lumen and basement membrane (BM).

RESULTS: The average hormonal levels($\bar{x} \pm s$) were 217,0 ± 54,8 ng/dl from T; 16,3 ± 4,7 mUI/ml from LH and 11,2 ± 2,7 mUI/ml from FSH. Testicular histology were divided into 3 groups: 1) subtle dearrangement from GE with young cells in the lumen, TL diminishment and BM thickening with all germinal components presents in 4 (36,4%) cases. 2) TL diminishment, GE height diminishment with tunica propria thickening, marked hypospermatogenesis with focal maturation arrest (CITO II), predominance of SC in 5 (45,5%) cases. 3) absence of GE with BM thickening, TL diminishment and a "Sertoli cell only" picture in 2 (18,1%) cases. The hormonal levels and the testicular histology from the prepubertal boy were similar to normal from age.

CONCLUSIONS: T levels but not LH or FSH were different and lower than normal controls. Althought there were no positive correlation between T levels and the degree of testicular dearrangement the highest gonadotrpin levels were founded among AIDS patients from group 2. These data suggest a pituitary-gonadal functional attempt of recovery in this group. In our cases testicular volume were under normal values, therewere tubular dearrangement and a concurrent disturbance of gonadal hormone levels. According to our findings we cannot exclude a double endocrine impairement at testicular and hypothalamic-pituitary level in AIDS.

M.B.P.267 HIV INDUCES GLUCOCORTICOID RESISTANCE IN MONONUCLEAR CELLS.

Balotta,Claudia*; Vago,T.**; Bevilacqua,M.**; Galli,M.*; Norbiato,G.** and Moroni,M.*.
* Clinic of Infectious Diseases, University of Milan;
**Endocrin Unit, "L.Sacco" Hospital, Milan, Italy.

Objective: To determine the mechanism of glucocorticoid resistance of mononuclear cells in some HIV-patients presenting clinical evidence of adrenocortical insufficiency (melanosis, marked hypotension, extreme fatigue and "water intoxication") but elevated levels of ACTH and plasma and urinary cortisol.

Methods: Saturation isothermes were constructed on mononuclear cells isolated by Ficoll-Hypaque, in 9 controls and 3 patients by adding increasing amounts of ^{3}H-dexamethasone (0.1-20nM). Non specific binding: 1µM. Results were evaluated by Scatchard analysis.

Results:

	K_d (nM)	B_{max} (fmol/10^6 cells)
1	14.2	39.5
2	4.4	17.7
3	6.1	14.5
Controls	2.2 ∓ 1.3	7.29 ∓ 5.2

Conclusions: The decrease of affinity (Kd) and the increase in glucocorticoid receptor number (B max) suggests peripheral glucorticoid resistence, with secondary ACTH and cortisol increase. HIV-infection may induce glucocorticoid resistance in man.

M.B.P.268 ASSESSMENT OF ADRENAL FUNCTION IN AIDS PATIENTS WITH DOCUMENTED CMV INFECTION -

Young, Mary* Taylor, T.** Pierce, P.* Georgetown University Hospital, Washington DC. (*Infectious Diseases **Endocrinology)

CMV infection occurs in up to 90% of pts with AIDS. Autopsy findings of adrenal infection by CMV are common.

OBJECTIVE: To assess the frequency of clinically significant adrenal insufficiency AIDS pts with documented CMV infection.

METHODS: 9 pts with severe CMV disease were assessed. 6 pts were evaluated at the time of initial hospitalization for induction with Ganciclovir (Group A). 3 pts were evaluated while on maintenance therapy (Group B). Serum sodium, potassium and serial BP's were obtained. A cortrosyn stimulation test was performed using 250 ug cosyntropin with cortisol levels drawn at time 0 and 60 min. Blood and urine were obtained for viral cultures.

RESULTS: 7/9 pts had normal cortrosyn stimulation tests. 2/9 pts had borderline tests, both represented advanced AIDS with multiple OI's and prior hospitalizations.

		-- mean --			Cmv/Cults		Cortrosyn stim		
Gp	#PTS	Na	K	BP	Blood	Urine	NL	Borderline	Abnl
A	6	135	4.5	108	0/4	2/4	5*	1***	0
B	3	137	4.0	112	0/1	0/1	2**	1***	0

* mean cortisol time 0 = 17.9, 60 min = 35.1. ** mean cortisol at time 0 = 10.1, 60 min = 26.7. *** cortisols at times 0 = 13.4 and 14.7, 60 min = 17.6 and 17.8.

CONCLUSIONS: In our ongoing series, normal adrenal function as assessed by cortrosyn stimulation was present in 5/6 pts at initial dx and 2/3 pts with ongoing disease. 2 pts had borderline stimulation tests. No patient had documented adrenal insufficiency. The incidence of clinically significant adrenal involvement would appear to be low with 2/9 pts having borderline responses requiring close follow-up. Pts with advanced AIDS appear to be at greatest risk of developing adrenal insufficiency.

M.B.P.269 MODIFICATIONS IN CIRCADIAN RHYTHMS OF PLASMA LEVELS OF CORTISOL, ACTH , TESTOSTERONE, AND ADRENAL ANDROGENS (DHEA AND DHEA-S) IN HIV-INFECTED MALE PATIENTS.

VILLETTE Jean-Marie*, BOURIN P.***, DOINEL C.**, MANSOUR I.**, BOUDOU P.*, FIET J.*

* Laboratoire de Biochimie Hormonale, Hôpital Saint-Louis, Paris; ** Laboratoire de Cytométrie en Flux, Institut National de Transfusion Sanguine , Paris, *** Centre de Transfusion des Armées, Clamart, France.

Objective: Nycthemeral variations in plasma levels of cortisol, dehydroepiandrosterone (DHEA) and its sulfate (DHEA-S), testosterone and ACTH were studied in seven CDC2 and six CDC4 male patients and fourteen healthy subjects in order to detect modifications in hormone secretions occuring in HIV infection at various stages of the disease.

Methods: Plasma hormone levels were all determined by radioimmunoassay. Blood samples were collected every 4 hours from 08.30 a.m. to 08.30 a.m. the next morning. The cosinor method was used in order to detect the existence of a 24-hour rhythm and Student's t-test was applied to compare 24-hour mean hormone levels (mesors) and rhythm amplitudes.

Results: A significant 24-hour rhythm was found for each of the five hormones in the three groups of subjects studied.The secretory pattern of each hormone was very similar from one group to another and no apparent difference appeared in the shapes of the curves found for the various groups of subjects studied. Compared with normal subjects, mesors were significantly higher for cortisol ($p<0.001$) and lower for DHEA, DHEA-S and ACTH ($p<0.001$ for each hormone) in all HIV-infected patients. Twenty-four hour adjusted mean testosterone levels were similar in controls and CDC2 patients and significantly decreased ($p<0.05$) in the CDC4 patient group.

Conclusion: Analysis of the circadian rhythms of plasma hormone levels clearly indicated an altered adrenal hormonal state in all HIV-infected male patients, even during the asymptomatic period of the infection. During this period, although patients already had elevated plasma cortisol and lowered adrenal androgen levels, no hypogonadism was found, according to plasma testosterone levels.

M.B.P.270 DISORDERS OF LIPID METABOLISM IN AIDS

Albrecht Falkenbach, St. Klauke, U. Unkelbach, W. März,
H. Förster, P.H. Althoff et al.
University Hospital,Frankfurt/ Main, FRG.

High triglyceride and low cholesterol serum levels are frequent findings in patients with AIDS.

For a more precise evaluation of the lipid metabolism besides triglycerides and cholesterol free fatty acids (FFAs), lipoproteins and apolipoprotein subfractions were determined in the serum (fasting state) of 25 patients with AIDS and 8 patients with ARC (all men) by standard laboratory tests and compared to clinical and other laboratory data.

The most striking deficiency was found in the high density lipoprotein (HDL)-cholesterol fraction, which was decreased (<35 mg/dl) in 76% of patients, with extremely low levels (<15 mg/dl) in 24 % caused by a lack of apolipoprotein A_1 (in 85 % of patients) and A_2 (in 64 % of patients).

Of the FFAs palmitoleic acid was deminished in 28 %, stearoleic acid in 21 %, and the essential FFAs in 39 % of patients.

Deficiency of HDL-Cholesterol and FFAs worsened with the stadium of the disease and the extent of emaciation.

High triglyceride and low HDL-Cholesterol levels are commonly encountered in hepatitis, yet in this study there was no indication of inflammatory liver disease to cause the alteration. The extremely low concentration of HDL-cholesterol due to apolipoprotein A_1 deficiency, mainly in emaciated patients remind of heterozygous Tangier disease, in which lymphadenopathy, splenomegaly and macrophage dysfunction predominate. A follow-up study evaluating the benefit of substitutional therapies has been started.

M.B.P.271 HYPORENINEMIC HYPOALDOSTERONISM ASSOCIATED WITH HIV-1 POSITIVITY

Bosson, D.; Bril, T.; Harnie, S.; Dewit, S.; Clumeck, Nathan
Free University of Brussels, Brussels, Belgium.

Objective. Hyporeninemic hypoaldosteronism,associated with HIV-1 infection has been reported (F. Kalin '87). In order to evaluate the occurence of this anomaly we set up a prospective study.
Methods. We measured plasma cortisol (F), aldosterone (Aldo) and renin activity (PRA) by specific radioimmuno assay as well as plasma and urinary ionogram in 217 HIV-1 infected caucasians (CDC stage 2 to 4). Control population was comparable for saxe, age, and sodium dietary content. Statiscal analysis was performed using Mann-Whitney test and multivariate analysis.

Table	number of	median	±	range
	subjects	F(ng/ml)	Aldo(ng/ml)	PRA(ng/ml xhr)
Controls	72	150(50-400)	0,13(0,04-0,39)	2,6(0,3-7,4)
		p < 0,05	p < 0,001	p < 0,001
HIV-1 +	217	179(40-470)	0,08(0,03-0,76)	1,6(0,3-10)

Results. F was significantly higher in patients than in controls (p < 0,05). Aldo and PRA were significantly lower in HIV-1 infected patients (p < 0,001). Neither of the parameters varied according to stage. Three patients presented an hyporeninemic hypoaldosteronism with persistent hyperkalemia.
Conclusion. Hyporeninemic hypoaldosteronism with intact glucocorticoid secretion in HIV-1-infection suggests a dysfunction of the juxtaglomerular apparatus rather than a primary adrenal damage (J. Glasgow,'85). The early presence of these features (stage 2) rules out any causal effect of opportunistic infections (stage 4) (L. Membreno '87), but suggests a direct effect of the virus or an auto-immune etiology.

M.B.P.272 COMPARISON OF THYROID BIOCHEMICAL ABNORMALITIES (TBA) IN ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS) AND OTHER ILLNESSES.

Bourdoux, Pierre; Bonnyns, M.; Clumeck, N.
Saint Pierre University Hospital, B-1000 Brussels, Belgium.

Transient TBA are currently observed in nonthyroidal-illnesses (NTI) and particularly in severe infections but their incidence in AIDS is not yet known. Therefore, we studied the thyroid function in 102 patients with AIDS (stages 1 to 4) aged 19-78 (group I), in 102 age-sex matched controls with various infectious diseases (group 2) and in 4302 unselected patients aged 15-99 (group 3), admitted to our medical service. Thyroid function was assessed by serum T4, T3, TBG, FTI (T4/TBG) and TSH. When a thyroid disease was suspected , a complete panel of investigations was performed including free T4 and T3, and TRH test.

A low T3 syndrome was observed in 20% of all patients, including AIDS patients. Thyroid diseases were found in one patient in group 1(1%) and in 84 patients in group 3 (2%). In clinically euthyroid patients, the other TBA were distributed as follows(in % in groups 1/ 2/ 3) : decreased T4 (7/3/2), decreased FTI (7/1/0.2), increased T4 (1/9/2.7), increased FTI (1/4/1.4), increased TSH (2/2/2). Moreover, in patients of group 3 with high TSH, 1.8% had normal FTI indicating euthyroidism. When compared to controls, patients with AIDS, although euthyroid, had significantly different mean values of T4 (AIDS vs Controls, 7.4 and 8.2 µg/dl, P<0.025), T3 (127 and 142 ng/dl, P<0.025), FTI (1.26 and 1.55 ng/dl, P<0.001), TSH (2.6 and 1.8 µU/ml, P<0.01). Mean serum thyroglobulin levels were not different in groups 1 and 2.

In conclusion : 1) Decreased T4 frequency is higher in AIDS than in other NTI although the proportion of true thyroid disease is the same; 2) abnormal TBG level accounts for more than half of TBA, particularly in patients with low T4; 3) consequently, FTI is the most appropriate tool for screening thyroid dysfunction in AIDS and NTI patients.

M.B.P.273 MYOCARDITIS IN INTRAVENOUS DRUG ABUSERS WITH AND WITHOUT ACQUIRED IMMUNODEFICIENCY SYNDROME: AN AUTOPSY STUDY

Roberts, James W.; Francis, C; Navarro C; Brown, J; El-Sadr,W Harlem Hospital Center, College of Physicians and Surgeons, Columbia University, New York, New York, USA.

Objective: To compare cardiac involvement in intravenous drug abusers (IVDA) with the acquired immunodeficiency syndrome (AIDS) to IVDA without AIDS.
Methods: Consecutive unselected autopsies in IVDA performed from 1983 to 1988 were reviewed. Of 177 autopsies of IVDA, anatomic, morphologic and histologic data were available in 42 patients (pts) (AIDS; 32 male, age 27-60) with AIDS (defined according to the clinical criteria of the Centers of Disease Control) and 25 pts (NON-AIDS; 14 male, age 31-58 years) without clinical AIDS. Myocarditis (MYOC) (Lymphocytic or plasma cell infiltration), dilatation of the left (LVDIL), right (RVDIL), or both ventricles (BVDIL), pericarditis (PERI), pericardial effusion (EFFUS) and endocarditis (ENDO) in both groups is shown below: (Some pts appear in more than one group.; *=p<0.05)

	MYOC	LVDIL	RVDIL	BVDIL	EFFUS	ENDO
AIDS (n=42)	24	5	7	4	10	7*
NON-AIDS (n=25)	17	4	3	3	4	15

Myocarditis is comparable in AIDS and NON-AIDS and is not related to cardiac chamber dilatation, pericardial disease or pyogenic infection. Severe bacterial infection, particularly endocarditis, is common in NON-AIDS (87%) but uncommon in AIDS (5%). Opportunistic infection occurs in AIDS and is not related to MYOC. In IVDA, with and without AIDS, myocarditis is common but unrelated to other pathologic states.

M.B.P.274 THE PATHOLOGY OF THE MALE GENITAL TRACT IN AIDS.

Shevchuk, M.; da Silva, M.; Cronin, William, Armenakas, N.; Fracchia, J. and Tannenbaum, M.* Lenox Hill Hospital, New York, N.Y., *Veterans Administration Hospital, Bronx, N.Y. USA.

Objective. The male genital tract of AIDS patients frequently contains lesions and abnormalities which could be clinically asymptomatic.
Method. To study the pathology of AIDS of the male genital tract, the prostates and testes of 80 consecutive AIDS autopsy cases were examined histologically and 14 were stained with the p17 anti HIV monoclonal antibody.
Results. The following opportunistic infections were identified; Toxoplasmosis of testes (2 cases), cytomegalovirus (5 cases - 1 testis, 4 prostates), candidiasis of prostatic urethra (1 case). Seven tumors were identified in the series. Three were apparently unrelated to AIDS, namely 1 Sertoli cell adenoma, and 2 well differentiated stage A prostatic carcinomas. The AIDS related neoplasms were 1 Kaposi's sarcoma of testis, 2 non-Hodgkin's lymphoma involving testes and prostates, and 1 primary immunoblastic lymphoma of testis. In addition marked spermatogenic arrest, germ cell degeneration, peritubal fibrosis and Leydig cell depletion were seen in all cases. The anti HIV p17 monoclonal antibody showed small random foci of positive staining in 8 of 14 testes cases studied, located over one or several degenerating germ cells. Nine of 14 prostates showed few minute foci of epithelial staining.
Conclusion. The male genital tract of AIDS patients contains opportunistic infections, neoplasms and apparent direct infection by the HIV virus.

M.B.P.275 GENITOANAL ULCERS IN HIV-INFECTION

Ochsendorf,Falk R., Schöfer,H. and Milbradt,R.
Klinikum J.W.Goethe-Universität,Dept.of Dermatology,Frankfurt, FRG.

Objective. To examine frequency, etiology and significance of genitoanal ulcers in HIV-infected patients.-
Methods. 267 HIV-positive patients (84% male homosexuals, 16 % other risk groups; 19 asymptomatic (SLS), 87 LAS, 76 ARC, 85 AIDS) were examined repeatedly over a 4 year period. Genitoanal ulcers were examined clinically, microbiologically, serolgically and partly histologically.-
Results. Herpes simplex was the most important cause for anal ulcers:55/267 (21%) had at least one episode of ulcerating herpes analis. Incidence increased with advancing stage of HIV-infection: SLS none, LAS/ARC 15 % (32/162) and AIDS 33 % (29/87). The ulcers were atypical: extremely painful,"punched-out" lesions, showing no tendency to heal. On first manifestation the mean absolute CD 4-T-lymphocyte-count was 319/µl (lowest normal limit=490µl). 80 % of cultures showed positive results (HSV II=90%, HSV I=10%). Oral acyclovir was effective even in a dosage of 5 x 200 mg/d for 5-10d.- 2 genital ulcers were caused by treponema pallidum, once in combination with haemophilus ducreyi. Clinical picture and therapy were unremarkable.- Aphthous genital and oral ulcers occurred during the acute HIV-illness.-
Conclusion: Genitoanal ulcers should always remind of a possible HIV-infection. Furthermore, ulcerating herpes analis is a distinct clinical marker for a severe cellular immunodeficiency.

M.B.P.276 NEED FOR GYNECOLOGIC PROTOCOLS IN AIDS PRIMARY CARE CLINICS.

Marte, Carola; Ribble, D.; Keyes, C.; Wolbert, J.; Rodgers, P.; Kelly, J. Bellevue Hospital Center/Community Health Project, NY, NY, USA.

Objective: To develop a protocol ensuring effective recognition and management of gynecologic disease in the increasing number of women attending a primary care clinic for HIVAb+ patients. Methods: A protocol was designed on the basis of: (1) a questionnaire on gynecologic symptoms and disease administered to 178 HIVAb+ women at our clinic; (2) review of literature and other available data on gynecologic disease in At Risk and HIVAb+ women with respect to prevalence, natural history and management of specific diseases; (3) review of currently available AIDS medical management guidelines. Results: Genital herpes and candidiasis, PID, and papilloma virus disease (condylomata, cervical dysplasia and carcinoma) were identified as diseases of particular concern in the management of HIVAb+ women. These diseases were found to be more prevalent, more aggressive, chronic and recurrent, and to require more extensive or different treatment than in HIVAb- women. They are not included in most current guidelines for medical management of HIVAb+ patients, and most gynecologic protocols in primary care have not been modified for HIVAb+ women. Conclusion: Providers should be informed on the unusual manifestations of gynecologic disease in HIVAb+ women. Conversely, severe or recurrent STDs should suggest the need for HIV counselling and testing. Special gynecologic protocols and services are necessary but not yet designed for effective management of At Risk and HIVAb+ women. Data is available for improved management of these patients in the primary care setting, and a trial protocol is now being tested in our clinic.

M.B.P.277 OUTCOME OF PATIENTS WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV) ON CHRONIC DIALYSIS (D).

R. Perez Garcia, J. Luño, J.M. Lopez Gomez, A. Franco, F. Valderrabano, M.D. Gurbindo Gutierréz.
HOSPITAL GENERAL GREGORIO MARAÑON, MADRID, SPAIN.

In July 1987, we evaluated 165 adult patients undergoing Hemodialysis (HD) and CAPD;102 patients with a functioning kidney allograft (Tr) and 126 staff caring for them, for HIV infection. All patients and staff were evaluated serologically by ELISA (Abbot) to identify antibodies to specific HIV antigens. Each positive ELISA was confirmed by Western Blot, in two samples. There were two false positive ELISA reactions.

Prevalence of HIV infection (HIV+) was 2,7% in D; 1% in Tr and 0 in staff. Only one out of 6 HIV + patients was intravenous drug user (IDU),the remaining have not any other risk factors than blood trasfusions and 3 of them a previous Tr. Also 2 patients with IDU-HIV-associated nephropathy requiring chronic maintenance D were included in this study.

The 8 HIV+ patients,4 men and 4 women,aged 18-66, were followed during more than 18 months or till they died. Two HIV+ patients were on CAPD; 5 continued on HD,in an isolated unit, and the last one was Tr.The D sessions were performed using CDC guidelines for HIV preventing contagion. None new HIV+ patient has been observed in the periodically ELISA tests performed every 4 months in patients on D or Tr. All patients but one had OKT4 count and OKT4/OKT8 rate reduced.Three out of 8 HIV+ patients developed Acquired Immunodeficiency Syndrome (AIDS) (CDC 1987) and they died between 12-30 months after HIV+ was first observed.Two out of 3 patients who developed AIDS were IDU and the remaining only had blood trasfusions as known risk factor.

Blood transfusion or Tr, before 1987 was a likely way of contamination for HIV in our area. HIV+ patients on D had a high risk to develop AIDS. AIDS patients on D had a poor prognosis.

M.B.P.278 HENOCH-SCHONLEIN PURPURA & IgA GLOMERULONEPHRITIS ASSOCIATED WITH H.I.V. INFECTION

Thompson Ian, Cooper D., Savdie E., Gold J., Melville R.,
St.Vincents Hospital, Sydney, Australia.

Objective: A case of Henoch-Schonlein purpura & IgA glomerulonephritis in association with H.I.V. infection is described.

Results: 33 yr.Caucasian male (H.I.V. +ve since '85)developed purpuric rash on trunk, legs & buttock(typical H.S. distribution)with arthalgia in Nov.'87 & required 2 months steroid therapy until symptoms cleared. At presentation CD4 413 (500-1400) P24 antigen reactive 1+protein & blood on urinalysis. IgA↑3.14 (0.53-0.48 g/l). FBC,ESR,MBA & immunology screen negative. AZT commenced May'88. Subsequent anaemia required transfusion and dose reduction. Bacterial pneumonia Nov'88 treated with amoxycillin followed by acute renal failure. Creatinine 0.1mmol/l 23/10/88, 0.47mmol/l 3/11/88. Creatinine clearance 10/11/88 0.5 (1.5-2.5mL/s). 24 hour urinary protein 1.67 grams (vol.1014 - 0.3ml. creat.clearance). Urinalysis 4+ blood & protein. Renal biopsy "segmental necrotizing glomerulonephritis with IgA deposition consistent with H.S. syndrome supported by I.F. AZT ceased. Rx with pulse steroids & cyclophosphamide - developed haemorrhagic cystitis. Creatinine 0.25 16/12/88 with CD4 95, antigen +ve.

Conclusion: A case of classical H.S. purpura is described, initially responding to steroids, progressing to acute renal failure following an episode of pneumonia treated with amoxycillin. The patient was known to be H.I.V. & P24 antigen positive at onset of illness. The association has rarely been described & is not the typical picture of H.I.V. associated glomerulonephritis, i.e. focal segmental glomerulosclerosis with a nephrotic picture.

M.B.P.279 OUTCOME OF KIDNEY TRANSPLANTED PATIENTS WITH HIV

[illegible] R.R.,Pereira C.A.P.,Stabile C., Pacheco A.S.,Acetturi C.A.,Peixinho Z. Divisions of Nephrology, Infectious Diseases and Immunology. Escola Paulista de Medicina - Brasil.

The choice of renal transplantation for ESRD(End Stage Renal Disease) has been controverse since the first descriptions of such patients infected with HIV. We have followed up six(06) transplanted patients who had positive ELISA for HIV(confirmed by IMMUNOBLOT). All of them had diagnosis made after transplantation. Four(4) had sera collected before transplantation, that were available and tested for anti HIV.

Pat	sex	HIVdef Transp	Route Transm	Don	Drug	Follow up TimeTx	Follow up TimeDiag	Class	Creat
01	M	+	B.T.	L	P+A	38	38	IV C	1.6
02	M	+	B.T.	L	P+A	33	33	IV C	1.0
03	F	+	B.T.	c	P+C	17	17	III	1.2
04	M	-	K.A.	c	P+C	19	07	II	1.4
05	M	?	B.T.	L	P+A	28	07	II	1.3
06	M	?	D.A.	L.	P+A	96	04	II	1.0

Class=CDC.Classification,Creat=Seric.Creatinine(mg/dl), L= Living.donor,c=Cadaveric.donor,P=Prednisone,A=Azathioprine C=Ciclosporine,K.A.=Kidney.Allograft,D.A.=Drug.Addict,B.T.= Blood transfusion.Follow up time = Months.

The average follow up after transplantation was 38.5 months, and 16 months for HIV diagnosis. Two patients presented opportunistic infection(CMV retinitis and oral candidiasis). The good results in this short serie and the absence of a control group (HIV positive patients on dialysis treatment) do not allow us to conclude wich modality of treatment offers the best survival. Therefore we may not assume a policies of denying cadaveric allografts to ESRD patients infected with HIV.

M.B.P.280 LACK OF CLINICAL EVIDENCE FOR A GLOMERULOPATHY (GP) IN 203 PATIENTS WITH HIV-INFECTION

Brunkhorst, Ulrike; Brunkhorst, R.; Tschecne, B.; Eisenbach, G.; Schedel, I. and Deicher, H.
Hannover Medical School, Hannover, F.R. Germany.

Objective. Several authors described a nephrotic syndrome, frequently progressing to renal failure in more than 20% of patients with HIV-infection of different stages. Though renal histological changes were rather unspecific these authors postulated the existance of a HIV-associated GP. We therefore investigated proteinuria (PU) and serum creatinine (S-crea) in 203 HIV-patients.

Methods. 122 patients (gr1) had early stages of the disease without opportunistic infections (O.I.), 81 patients suffered from acute O.I. (gr2). In case of positive qualitative test (Combistix), quantitative measurement of PU (Biuret) was carried out; when PU was 0.5 g/l SDS-gel-electrophoresis (EPHO) was performed.

Results. None of gr1 patients had a PU 0.5 g/l or an elevated S-crea. 10/81 patients of gr2 had a PU between 0.5 and 3 g/l, one further of gr2 patients developed a transient PU of 4.7 g/l. Only 3 of the proteinuric patients had a glomerular pattern in EPHO, all 3 had CMV- or EBV-infections.14/81 patients showed a transient elevation of S-crea (x±SD of the max. S-crea: 164±43 umol/l) during pentamidine therapy for pneumocystis carinii infection, 1 PT treated with high dose acyclovir had to be temporarily dialyzed.

Conclusion. In our 203 HIV-patients no nephrotic syndrome and no sustained elevation of S-crea was observed. All cases of PU and transient elevations of S-crea were associated with severe O.I. and high doses of potentially nephrotoxic antibiotics.

M.B.P.281 NEPHROPATHY AS THE INITIAL SIGN OF AIDS:

LUIZ PAULO J. MARQUES,OMAR R. SANTOS, GUILHERME S. LOPES, ALBANITA V. OLIVEIRA,FRANCISCO FIALHO,EUGENIO PACELLI Q. MADEIRA,CLINICA MEDICA III, ESCOLA DE MEDICINA E CIRURGIA, UNI-RIO,BRASIL.

AIDS-associated nephropathy is characterised by the presence of focal and segmental glomerulosclerosis (FSGS) with rapidly progression to terminal renal failure. We study 303 HIV-infected patients, 280 men and 23 women. Risk factors were: 221 homossexuals, 37 hemophiliacs, 14 unknown, 13 heterossexual contacts, 12 blood transfusion, 6 IV drug addicts. We found nephrotic syndrome(NS) in 3 (0.9%) associated with azotemia in 2 (moderate in 1 and severe in 1). Renal biopsy showed FSGS in 2 an diffuse glomerulosclerosis in 1. All progressed to terminal renal failure, 2 died 2 an 14 months after the onset of NS. One has been submitted to maintenance hemodialysis for ten months.

In 2 patients(IV drug addict and unknown risk factor) the diagnosis of HIV infection was only possible when they presented opportunistic infections, 3 and 4 months after the onset of NS.

We conclude that NS may be the initial manifestation of HIV disease and we suggest that anti-HIV tests should be done in all adult nephrotic patients.

M.B.P.282 THE TREATMENT OF INFECTIOUS CAUSES OF AIDS-ASSOCIATED HEART DISEASE.

E.L. Kinney, M.D., J.-J. Monsuez, M.D., Reed Institute, Miami, FL, USA, and Hospital Saint-Louis, Paris, France.

Although we have found that some infectious causes of AIDS-associated heart disease are treatable, it was unclear if the odds of successful treatment were altered because of the presence of cardiac involvement. We therefore analysed the results of treatment in our own patients and in patients reported in the literature. Successful treatment of infection was defined as eradication of the cardiac pathogen after completion of the intended course of therapy. We found that the odds of successful treatment for tuberculous pericarditis were substantially lower than if the tb was extracardiac (33% vs. 60%). The only factor that separated those who succeeded from those who failed therapy was an elevated gamma globulin in those who succeeded. Symptomatic cardiac disease due to M. avium resulted in extremely short survival, regardless of treatment. For symptomatic cryptococcal myocarditis, the odds of successful treatment were no different in AIDS patients with extracardiac disseminated cryptococcosis. But it was only in cryptococcal myocarditis that improvement in cardiac function was demonstrated during specific therapy. S. typhimurium endocarditis (STE) was eradicated using conventional medication only, and did not relapse, even though no maintenance therapy was given. This suggests that STE may be easier to treat than S. typhimurium bacteremia without a known focus of infection. T. gondii heart disease appears to require at least 2 months of treatment. These observations suggest that although some infections are less likely to respond to treatment if there is cardiac involvement, mostly the response to treatment is similar to the response with only extracardiac disease.

M.B.P.283 ECHOCARDIOGRAPHIC ABNORMALITIES IN AIDS

Reichert S, Visser C, Danner S and Dunning A.
Departments of Cardiology and Medicine (AIDS-unit), Academic Medical Center, Amsterdam, The Netherlands.

Objective. To determine cardiac involvement in AIDS.

Methods. Two-dimensional echocardiography was performed in 32 consecutive patients (mean age: 39 years; range 26–66), with AIDS, CDC-classification IV–C, who did not have cardiac complaints.

Results. Pericardial effusion was present in 13/32 patients (39%). Valvular abnormalities were present in 5/32 patients (15%), of whom 2 had vegetations and 3 a prolapsing mitral valve leaflet. Wall motion abnormalities were seen in 21/32 patients (63%) and varied from moderately depressed regional myocardial function to overt, severely impaired global left ventricular function (5 patients).
Cardiac abnormalities were absent in only 2 patients (6%).

Conclusions. Cardiac abnormalities are common in patients with AIDS and usually led to - subclinical - affection of myocardial function.

M.B.P.284 CHARACTERISTICS OF PATIENTS WITH AIDS-ASSOCIATED HEART DISEASE BUT NO DEMONSTRABLE CARDIAC PATHOGEN.

Eylin L. Kinney, M.D., Jean-Jacques Monsuez, M.D., M. Toussaint, M.D., The Reed Institute, Miami, FL, USA, and Hospitals Saint-Louis and Cochin, Paris, France.

We retrospectively studied 41 adult patients (18 known to us, 23 from the literature) with AIDS and symptomatic heart disease in whom the cause of the heart disease was assessed by culture and/or biopsy. Fifteen (36%) had no demonstrable cardiac pathogen (NoPath), 13 had infectious pericarditis, 8 had infectious myocarditis and 5 had a cardiac tumor. The NoPath group had a higher proportion of intravenous drug abusers and a much lower proportion of homosexuals (0.07, Newman-Keuls). Most (93%) in the NoPath group had AIDS rather than AIDS-related complex (ARC), whereas 38% of the infectious pericarditis group had ARC ($p=0.04$, X^2). The interval from the onset of AIDS or ARC to cardiac symptoms averaged 15.4 months in the NoPath group, versus 5.3 months in the groups with a cardiac pathogen (with 3 month cutpoint, $p=0.024$, Fishers). The NoPath group tended towards a higher frequency of prior P. carinii infection ($p=0.07$, Fishers), and all groups but those with cardiac tumor had a lower rate of prior cutaneous Kaposi's sarcoma ($p=0.04$, X^2). Other infections were equally distributed between groups. HIV was isolated from the heart in only 2 patients (pericardial fluid in 1 patient with infectious pericarditis; in the myocardium of 1 patient in the NoPath group). These data suggest that finding no demonstrable pathogen in an AIDS patient with symptomatic heart disease is common, may be due to a prior, healed infection, perhaps related to P. carinii, and probably is not due to a direct cardiac effect of the HIV virus.

M.B.P.285 LEFT VENTRICULAR DYSFUNCTION IN AIDS PATIENTS WITH SEVERE PNEUMOCYSTIS CARINII INFECTION.

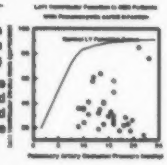
Wood, Robert D.; Akil,B.; Tuchschmidt,J.; Swinney,R.S.; Boylen,C.T..
LAC/USC Medical Center, GH 11-900, 1200 North State Street, Los Angeles, CA, U.S.A.

Objectives: Respiratory failure, secondary to *Pneumocystis carinii* infection (PCP) continues to have an extremely high mortality. Cardiomyopathy has been described in patients with AIDS (Raffanti SP, 1988). In this study we examined the hemodynamics of patients with PCP and severe respiratory failure.

Methods: We evaluated twelve patients (age = 34+/-8 yrs) with AIDS, documented PCP and severe respiratory failure (FIO2 = 0.85+/-0.16) requiring PEEP. We chose subjects who had no evidence of any concomitant bacterial, fungal, mycobacterial or viral infection as affirmed by lack of clinical site and negative cultures, including blood. Hemodynamic data were obtained with a balloon tipped pulmonary artery catheter. Cardiac outputs were obtained by thermodilution. Data were examined on admission to the ICU and at 12 and 24 hours.

Results: Our data showed:

	Pulse	MAP	MPAP	RA	PAOP	CI	LVSWI	SVR
Init	118 + 21	88 + 16	32 + 9	14 + 6	14 + 4	4.3 + 1.1	33 + 12	614 + 226
12hr	122 + 22	71 + 14	26 + 10	13 + 3	15 + 3	4.3 + 1.7	26 + 17	[illegible] + 103
24hr	122 + 22	77 + 14	27 + 9	16 + 6	17 + 4	4.4 + 1.8	40 + 19	[illegible] + 186



Conclusion: Our patients with PCP demonstrated a hyperdynamic state not unlike that associated with sepsis. We found them to have profound myocardial dysfunction, with left ventricular function curves shifted downward and to the right. This may have therapeutic implications in the management of AIDS patients with respiratory failure due to PCP.

M.B.P.286 ELECTROCARDIOGRAPHIC CHANGES IN PATIENTS RECEIVING PENTAMIDINE FOR THE TREATMENT OF PNEUMOCYSTOSIS.

Akil,Bisher; Gonzalez A; Bhandari A; Sager P;Leon C; Rahimtoola SH.
Department of Internal Medicine, University of Southern California, Los Angeles, California, U.S.A.

Objectives: In 1987, two patients developed torsade de pointe (TDP) on pentamidine for the treatment of *Pneumocystis carinii* pneumonia (PCP)in the absence of electrolyte abnormalities..The purpose of this study was to study the electrocardiographic effect of pentamidine (PTM)..
Results: WE prospectively obtained a serial of 12-lead ECG studies in 10 consecutive patients with AIDS and PCP who were receiving PTM.The ECG was obtained before administration of PTM, and 2.6 ± 0.8 days (cumulative dose of PTM 852 ± 414 mg).and 7.2 ± 1.1 days (cumulative dose 1882 ± 586 mg) after therapy. No patient had overt heart disease,thyroid abnormality or electrolyte disturbances.
Results: The heart rate at baseline was 88 ± 16, and that did not change on day 2.6 (97 ± 21) or day 7.2 (86 ± 22).Similarly, the PR interval of 146 ± 19 ms remained stable at days 2.6 (145 ± 22) and 7.2 (147 ± 21).Also QTc 0f 422 ± 22 remained unchanged (419 ± 20 on day 2.6 and 436 ± 32 on day 7.2).Although one patient had mild QTc prolongation from 420 to 510 ms there was no other ECG abnormality.
Conclusion: 1.Pentamidine produced no significant dose related ECG effects. 2.TDP appears to be an idiosyncratic complication of PTM.3.Abnormal QTc prolongation during therapy with PTM is relatively rare and when present, should be treated as a warning sign of impeding TDP.

M.B.P.287 *STAPHYLOCOCCUS AUREUS* ENDOCARDITIS IN HIV(+) AND HIV(-) INTRAVENOUS DRUG ABUSERS

Poblete, Rita; Sone, C; and Fischl, M. University of Miami School of Medicine, Miami, Florida, USA.

Objective. To evaluate the clinical presentation and outcome among HIV(+) and HIV(-) intravenous drug abusers (IVDA) with *S. aureus* endocarditis.
Methods. Retrospective chart review of 50 patients hospitalized for *S. aureus* endocarditis between March 1985 and November 1988 was done. 32 were HIV(+) and 18 HIV(-). 3 patients seroconverted. Age, sex, race, medical history, physical exam, laboratory parameters and outcome were assessed.
Results. Mean age was similar in both groups. More women (63%) than men (37%) were noted in the HIV(+) group. No difference in sex distribution was seen in the HIV(-) group. In HIV(+) group, 78% were black american; 19% white, and 3% hispanic. No racial differences were noted in the HIV (-) group. Fever-78% and cough-25% were less frequent presenting symptoms in HIV(+) compared with 95% and 72%, respectively, in HIV(-). No differences in physical and chest X-ray findings were noted. Mean hemoglobin (11.7) and white count (14.2) were higher in HIV(-) patients than HIV(+), respectively (10.8 and 10.5). More vegetations were identified in the HIV(-) group than HIV(+) (58% vs 24%). Recurrence of *S. aureus* endocarditis was the same in both groups. 4 patients had prior or concurrent opportunistic infections (OI). 4 developed OI within 10 mos of endocarditis. 8 HIV(+) patients died; 6 of complications of endocarditis, 1 of PCP, and 1 of an unrelated cause.
Conclusion. HIV(+) patients with *S. aureus* endocarditis were more likely to be black american women. Poor outcome and high fatality rate favored the HIV(+) group.

Néoplasme
Neoplasm

M.B.P.288 POLYCLONAL AND MONOCLONAL B-CELL LYMPHOMA IN AIDS

Kaplan Lawrence D*, Meeker T**, Feigal E*, Heradier B*, Khayam-Bashi F*, Grimaldi C**, McGrath MS*. Departments of Medicine and Pathology*, San Francisco General Hospital, San Francisco, CA.
Department of Medicine**, Veterans Administration Medical Center, San Francisco, CA, U.S.A.

Objectives: The identification of clinical characteristics associated with two molecular subgroups of AIDS-associated B-cell lymphoma.
Methods: Immunoglobulin gene rearrangement studies and DNA dot-blot analyses for Epstein-Barr virus (EBV) were performed on 23 lymphoma tissue specimens obtained at diagnosis from patients with AIDS-associated non-Hodgkin's lymphoma (NHL) and correlated with clinical features.
Results: Fourteen tumors were identified as monoclonal and nine as polyclonal. The polyclonal lymphomas included immunoblastic (6), diffuse large cell (2), and small noncleaved (1) histologies. Monoclonal lymphomas included immunoblastic (8), small noncleaved (5), and large cell (1). Six primary CNS lymphomas were all monoclonal, immunoblastic. EBV DNA sequences were identified in 4 of 7 monoclonal samples and 1 of 4 polyclonal samples. Non-CNS lymphoma patients with polyclonal disease (n=7) lived longer (median 12 vs 3.5 mos;p=.003), had higher total T4 cell counts (369 vs 120/mm^2; p=.01), and were more likely to have Stage I disease (4/7 vs 0/6;p=0.07) than those with monoclonal non-CNS disease. The frequency of a prior AIDS diagnosis, performance score, and the frequency of extranodal disease (known prognostic features) were similar in each group.
Conclusions: Molecular analysis suggests two disease processes in patients with AIDS-associated NHL, each associated with distinct clinical features and prognosis.

M.B.P.289 KAPOSI'S SARCOMA IN PATIENTS WITH HIV INFECTION

Latif. Ahmed, Houston S, Neill P, Bassett M, Thornton C, Sitima,J et al University of Zimbabwe Medical School and Harare Blood Transfusion Service, Harare, Zimbabwe

Objective. To study the clinical features and response to treatment of KS in patients with HIV INFECTION.
Methods. All patients with HIV infection and histologically proven KS were studied. For staging purposes fibreoptic endoscopy was carried out. Patients were treated with combination chemotherapy using actinomycin D, vincristine and bleomycin.
Results. 101 (82%) patients were male and 22 (18%) were female. The mean age of males was 34 years and that for females was 31 years. Generalised lymphadenopathy was found in 107 (87%) patients. Skin lesions in the form of nodules, plaques or diffuse infiltration were found in 115 (93%) patients. 6 patients had mucosal lesions of KS, lymphadenopathy but no skin lesions while 2 had only lymphadenopathic KS. Mucosal lesions were found in the buccal cavity (52%), in the nasopharynx (4%), on the conjunctivae (7%), in the bronchi (17%). Two patients had concomitant infection with Pneumocystis carinii. 98 patients were treated and of the 76 evaluated treatment failure occurred in 18 (23%) while partial or complete remission occurred in 58 (77%). The cumulative death rate for a 24 month period was 35.8%.
Conclusions. Patients with AIDS-related KS respond well to chemotherapy with an initial dramatic improvement. However relapses frequently occur. Patients with pulmonary KS have a poorer prognosis.

M.B.P.290 LYMPHOMAS IN PATIENTS WITH HIV INFECTION.

Carlos del Rio*, Guarner J§; Carr D*; Hendrix LE*. §Emory University and the *Crawford W. Long Hospital of Emory University, Atlanta, GA, U.S.A.

OBJECTIVE: We identified 18 patients with AIDS, AIDS-related complex or with serological evidence of HIV infection, seen at a single hospital since 1982, and analysed the clinical presentation, type of lymphoma, treatment and outcome to better understand their disease.
METHODS: Retrospective review of medical records and prospective follow up of patients seen since July of 1988.
RESULTS: 16 patients had non-Hodgkin's lymphoma (NHL); 1 Hodgkin's disease, and 1 had the simultaneous presence of both Hodgkin's disease and NHL. All patients were white homosexual men with a mean age of 38.2 years. In 47% this was the initial presentation of HIV infection. We classified 65% of the NHL as high grade (7 small noncleaved, 2 large cell, immunoblastic, and 2 high grade otherwise unclassifiable), 29% as intermediate grade (5 diffuse large cell), and 1 patient had a low grade lymphoplasmocytoid lymphoma. Extranodal involvement was present in 47% with the gastrointestinal tract and the liver being the common sites. Of 12 patients treated with chemotherapy, 7 treated with MACOP-B, achieved complete remission. However, one patient relapsed after 86 weeks. Both patients with Hodgkin's disease had an aggressive course with poor response to therapy.
CONCLUSIONS: High grade malignant lymphomas, frequently with atypical presentations, occur in patients infected with HIV and should be treated with intensive chemotherapy regardless of stage. The response to treatment with MACOP-B is favorable; however, late relapses can occur.

M.B.P.291 KAPOSI'S SARCOMA - CLINICAL DISTRIBUTION, OPPORTUNISTIC INFECTIONS AND SURVIVAL.

Ismael, Carla; Pacheco, R.G.; Dias, M.G.; Eyer-Silva, W.A.; Miguez, L.A.; Morais de Sá, C.A.
Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil.

Objective: To evaluate the clinical distribution, Opportunistic Infection (OI) and survival of AIDS patients with Kaposi's Sarcoma (KS).
Methods: Of 235 patients meeting the CDC case definition for AIDS, 59 (25,10%) were diagnosed with KS. These were evaluated for clinical distribution and examined for occurence of opportunistic infections. Cumulative survival rate was assessed in 22 patients (Cutler, Ederer 1958) with KS with and without OI.
Results: Kaposi's Sarcoma occurred in 59 male patients, 35 homosexual (59,32%) and 26 bisexual men (44,00%). The skin was involved in 54 patients (91,5%), lymphnodes 16 (27,11%), gastrointestinal tract 16 (27,11%), lung 3 (5,08), genitourinary tract 2 (3,38%) and brain 1 (1,7%). We observed infections in 48 (81,35%). Candidiasis was the most frequent OI occurring in 39 patients (66,10%), Mycobacterium tuberculosis in 13 (22,03%), Criptosporidium in 10 (16,94%) and cerebral toxoplasmosis in 9 (15,25%). The proportion surviving one-year among 22 patients with KS with and without OI was 85%, two-year-survival 25% and three-year and four-year survival was 14%. Among 18 patients with both KS and OI, one-year-survival was 70% but a sharp drop occurs thereafter: by two years only 7% survive and none survive three years.
Conclusions: The prevalence of KS in our AIDS patients is high (25,10%). All patients were homo/bisexual men. The majority of KS involved skin, lymphnodes and GI tract. Opportunistic infections seem to be responsible for decreased survival in KS.

M.B.P.292 LOWER GENITAL TRACT NEOPLASIA. ITS INCIDENCE IN HIV INFECTED WOMEN AND THE ROLE OF HUMAN PAPILLOMA VIRUS (HPV) AND OTHER RISK FACTORS.

J R SMITH, M BYRNE, M BOTCHERBY, P MUNDAY, D TAYLOR-ROBINSON, S M FORSTER. The Department of Genito-Urinary Medicine, The Praed Street Clinic, St Mary's Hospital, London, United Kingdom.

A high incidence of cervical dysplasia has been noted in HIV positive women. Therefore, 29 women infected with HIV were studied cytologically and by colpobiopsy. Results are as follows:

	Mode of Transmission										
	IV	Hetero.	B. Trans.	NORMAL	ATYPIA	CIN*	INV*	VIN*	VAIN*	CLINICAL HPV	SUBCLINICAL HPV
No of patients	14	12	3	5	1	10	0	3	0	12	8
% of patients	48%	41%	11%	17%	3%	34%	0%	10%	0%	41%	28%

69% of our study group had evidence of HPV infection and 41% had lower genital tract neoplasia. However, these high percentages may be a function of increased exposure to other well recognised risk factors for such disease, eg. age of first sexual intercourse, number of sexual partners, smoking etc. We will present the results of a study, including HPV sub-types, carefully controlled for these factors and designed to investigate the role of HIV and the immunosuppression incurred as a result of HIV infection in the increased incidence of lower genital tract neoplasia in this group.

* CIN = cervical intra-epithelial neoplasia. VIN = vulval intra-epithelial neoplasia.
INV = invasion, micro or macro. VAIN = vaginal intra-epithelial neoplasia.

M.B.P.293 MALIGNANT NEOPLASMS IN SURGICAL SPECIMENS OF DIFFERENT AIDS RISK GROUPS.

M Vasquez MD; Heidrun Rotterdam MD; G Sidhu MD; NYU Medical Center, New York, NY, U.S.A.

We examined 1107 surgical specimens from 323 AIDS patients to determine frequency and site of malignant neoplasms (MN) and differences, if any, among the two major risk groups of homosexuals (HS) and IV drug abusers (IVDA). There were 121 patients (37%) with MN, including 88 (27%) with Kaposi's sarcoma (KS), and 27 (8%) with malignant lymphoma (ML). Four HS had both KS and ML. Five patients had squamous cell carcinoma (SCC) and one prostatic carcinoma. KS was found in 73 of 178 skin biopsies (bx)(41%), and constituted the most common opportunistic disease (OD) at this site. KS was also found in 15 of 81 lymph node bx (19%), 10 of 194 digestive tract bx (5%), 8 of 329 lung bx (2.4%), 4 of 21 oropharyngeal bx (19%), and 1 of 73 liver bx (1.4%). KS was the first presenting OD in 69 of 88 (78%) patients. KS was 7 times more common in HS vs IVDA and was diagnosed in 70 of 187 HS (37%) vs 5 of 100 IVDA (5%). Malignant lymphoma (ML) was found in 14 of 81 lymph node bx (17%), 5 of 194 digestive tract bx (2.6%), 5 of 167 bone marrow bx (3%), 3 of 178 skin bx (1.7%), 2 of 8 brain bx (25%), and once each in soft tissue, liver, oral mucosa, and lung. ML was the first presenting OD in 17 of 27 (63%) patients. ML occurred with approximately equal frequency in HS and IVDA [20 of 187 HS (10%), 8 of 100 IVDA (8%)]. ML was, however, more frequently seen in extranodal sites in HS (16 of 24; 66%) than in IVDA (3 of 8; 37%). SCC occurred in larynx (2), anus (1), penis (1), and skin (1) and exclusively in HS. We conclude that KS is the most frequent MN in HS, and ML in IVDA. ML is more commonly extranodal in HS than in IVDA.

M.B.P.294 B-ALL in HIV-positive 27 y.o. man .

Nosari A.M.; de Cataldo F.; Gargantini L.; Landonio G.; Mura M.°; Oreste P.°
Department of Haematology and ° Pathology.
Niguarda Ca' Granda Hospital , Milan , Italy .

Objective. To present the clinical course of B-ALL in HIV-positive heroin abuser, the response to therapy and the autopsy findings .
Methods. 27 y.o. man, HIV-positive (CD4< 0.2 x 10^9/L and skin anergy) , heroin abuser, with lymphadenopaty , splenomegaly , anemia and thrombocytopenia . Acute oligoblastic leukemia with massive infiltration of bone marrow biopsy by FAB L3 lymphoblasts, PAS positive. Phenotype : Calla (CD10) 90% , CD 19,20 90% , DR 94% ; negative for T-cells and myeloid markers . Cytogenetic : t(8;14). The blasts cells were negative for EB Nuclear Antigen (EBNA). Chest X-ray, CAT, and cerebral fluid cytology were negative for tumour. Therapy: two courses of induction therapy (ciclophosphamide, vincristine, adryamicyn, and VP16) and CNS prophilaxis with methotrexate and prednisone.
Results. Poor and short partial remission was obtained. During aplasia bilateral pneumonia of u.o.. A few days later the patient developed dramatic blasts regrowth with fever,hemorragic diathesis and coma. Cerebral CAT : tumour of u.o. The patient died after "down-hill" course.
Autopsy findings : leukemic dissemination ; pulmonary cavitation by Aspergillus Fumigatus; cerebral tumour by leukemic mass.
Conclusions.B-LLA is rarely associated to HIV-infection: few, but increasing reports in literature. Some authors are the opinion that the current CDC classification of AIDS should be widened to include B-cell ALL in HIV-seropositive subjects.
The course was dramatic and therapy ineffective as reported by others authors.

M.B.P.295 UNUSUAL PRESENTATION AND CLINICO-PATHOLOGICAL CORRELATIONS IN NON HODGKIN'S LYMPHOMAS (NHL) ASSOCIATED WITH HIV INFECTION

E. OKSENHENDLER, J.P. FARCET, C. GISSELBRECHT, J.P. CLAUVEL, A. THYSS, M. RAPHAEL, PARIS, CRETEIL, NICE - FRANCE.

We have evaluated the potential correlations between histopathology, clinical expression and immunodeficiency status in 57 patients with NHL associated with HIV infection.

Histopathology (n)	Stage		CDC group		CD4 cells/mm³	
	I-IIE	III-IV	IV	II-III	< 200	> 200
Immunoblastic (13)	10	3	10	3	7	2
Diffuse large cell(29)	13	16	10	19	13	11
Burkitt (15)	2	13	4	11	3	8

Patients with immunoblastic NHL had low CD4 cell counts, belonged to CDC group IV and presented usually with localized extra-nodal tumor:skin(4), brain (2), gut (2), lung (1), kidney (1). Patients with Burkitt lymphoma had a disseminated disease with bone marrow involvement in 5/15 and central nervous system involvement in 4/15, but often asymptomatic HIV infection. Patients with diffuse large cell NHL had an intermediate status.

M.B.P.296 ABSENCE OF HLA DR5 AND KAPOSI'S SARCOMA IN TRINIDAD & TOBAGO

Courtenay Bartholomew*, V. Wilson**, F. Cleghorn***.
*The University of the West Indies;
**Department of Immunology, General Hospital, Port of Spain;
*** The Caribbean Epidemiology Centre, Port of Spain, Trinidad.

Although the association of Kaposi's Sarcoma (KS) and HLA Dr5 has not been found in all reports the majority of studies have shown an increased antigen frequency of DR5 and in some studies a concomitant decreased frequency of DR3 both in endemic KS and HIV associated KS. Trinidad and Tobago has a population of 1.2 million people comprising people of African origin (41%), Indian origin from North India (41%), Mixed race (16%), Caucasian 1% and Chinese 1%. The people of African origin came to Trinidad via the slave trade from 1680 and the Indians from North India as indentured labourers from 1845. Up to December 31, 1988 there were 389 cases of AIDS in Trinidad, 288 of whom were Afro-Trinidadians and 26 Indo-Trinidadians. However, there were only 3 cases of KS all of whom were in people of predominantly Caucasian ancestry. There is no IV drug abuse in Trinidad. Statistics of DR3 antigen frequencies show a frequency of 31.6 in African blacks, 28.0 in North American blacks, 29.0 in North Indians, 25.2 in Afro Trinidadians and 21.5 in Indo-Trinidadians. On the other hand, while the DR5 antigen frequencies were 24.8 in African blacks, 29.2 in N. American blacks and 22.6 in N. Indians, it was only 8.5 in Indo-Trinidadians and absent in Afro-Trinidadians. The absence of DR5 in this population may then explain the extremely low incidence of KS in Trinidad and Tobago and supports the epidemiological claims for an association between KS and DR5.

M.B.P.297 KAPOSI'S SARCOMA (KS) IN WOMEN WITH ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS)

Cheung, Tony W. and Siegal F. Queens Hospital Center(QHC)and Long Island Jewish Medical Center (LIJ), Jamaica and New Hyde Park, N. Y. 11432 and SUNY at Stony Brook, N. Y. 11794, U. S. A.

Most patients(pts) with AIDS related KS are male homosexuals. KS in female patients with AIDS is rare.
Objective. To survey cases of AIDS related KS in women and examine their clinical course.
Methods. Records from tumor registries and patient charts from private oncologists from QHC and LIJ were reviewed. A literature computer search was also used to look for cases of female AIDS related KS.
Results. Seven patients range in age from 23 to 34 years; 5 are black,1 Hispanic and 1 Haitian. Six patients, except the Haitian, are intravenous drug users. All pts developed opportunistic infections: oral candidiasis (7),Pneumocystis carinii pneumonia (3), genital herpes simplex(3),herpes labialis(1), CMV infection(2). All pts except one were diagnosed to have KS clinically and confirmed by biopsy; 6 have dermal involvement with visible skin lesions of the trunk and lower extremities. Chest x-ray of these 6 patients showed interstitial infiltrates. Bronchoscopy confirmed KS. The seventh patient presented with angioimmunoblastic lymphadenopathy; later right eye proptosis developed which, on biopsy, revealed non-Hodgkin's lymphoma. She expired 4 months later and on autopsy there was KS in the lung and stomach. Survival of all 7 pts was only 1 to 6 months (median 3-4 months).
Conclusion. Women with AIDS related KS have a very aggressive course. All cases presented have pulmonary involvement. We suggest that the putative etiological agent(s) can be transmitted by the intravenous route.

M.B.P.298 LYMPHOBLASTIC LEUKEMIA IN HIV-INFECTED PATIENTS

Minoli,Lorenzo;Maserati, R.; Pan, A.; Malfitano, A.; Sacchi,R Pagnucco, G.*. Infectious Disease and *Hematology Depts., IRCCS San Matteo, Università di Pavia, 27100 Pavia ITALY.

Among the hematologic malignancies arising in HIV-infected pts., acute lymphoblastic leukemia (ALL) is often classified as belonging to the FAB L3 subtype (Burkitt-like). We recently observed 2 cases of L3 ALL featured by almost the same biological findings but different clinical presentations.
CASE 1. A 45 yrs. old bisexual male was admitted for fever and purpura; no lymphnodal, hepatic or splenic enlargement was noticed. Peripheral and bone marrow studies showed the presence of large-sized, vacuolized, hyperbasophilic blasts, whose immunological pattern was: HLA-DR +; sIg + (IgM,IgG,λ); CD19 (B4) +; CD20 (B1) +; CD10 (CALLA) +. A 4-wk induction regimen with VCR, DOX and CYT, DEX plus i.t. MTX was completed and followed by 2 intensification courses with HD MTX, HD Ara-C, m-AMSA and VP16. Remission lasted 11 mos., until the pt. died despite salvage treatment (MITOX).
CASE 2. This 30 yrs. old male drug abuser was admitted with fever, diffuse skeletal pain and axillar lymphnodal, liver and splenic enlargement. His hematological disease was almost identical to that of case 1, with exactly the same blast markers. Paraplegia due to an intraspinal lymphomatous mass (showed by positive myelography) complicated the clinical presentation. Currently the pt. is being treated with the same induction regimen as case 1.
ALLs in HIV-infected pts. may present with a wide array of symptoms and require an aggressiva therapeutic approach,

M.B.P.299 PREDICTORS OF SHORTENED SURVIVAL IN PATIENTS WITH KAPOSI'S SARCOMA AND HIV-1-INFECTION

Tschechne, Barbara; Brunkhorst, U.; Schedel, I. and Deicher, H.
Hannover Medical School, Hannover, F.R. Germany.

Objective. To determine clinical, viral and immunological characteristics at the time of diagnosis of Kaposi's sarcoma in patients with HIV-1-infection in correlation to survival.
Methods. HIV-1-infected patients with biopsy proven Kaposi's sarcoma were contracted in this study.
Results. During observation period of this study (37 months) 21 patients with HIV-1-infection and Kapos's sarcoma were identified. 19/21 patients had contracted other bacterial, viral and/or opportunistic infections. In our study the prognosis of Kaposi's sarcoma depends on the appearance of other concomitant infectious agents such as Pneumocystis carinii, CMV etc. Furthermore the decrease of CD4/CD8-ratio, prevalence of specific p24-antigen i.e. and loss of specific antibodies to p24-core-protein corresponds with a poor prognosis.
Conclusion. Predictors of shortened survival in patients with HIV-1-infection and biopsy proven Kaposi's sarcoma included loss of specific antibody to p24, p24-antigenaemia, decreased CD4/CD8-ratio and/or appearance of opportunistic infections such as PCP.

M.B.P.300 TREATMENT OF DISSEMINATED MYCOBACTERIUM AVIUM (MAI) WITH CIPROFLOXACIN (CPF), ETHAMBUTOL (ETH), RIFAMPIN (RIF) AND AMIKACIN (AMK).

Chiu, Joseph; Nussbaum, J.; Bozzette, S.; Young, L.; Hesseltine, P.; and McCutchan, J.A., California Collaborative Treatment Group, USA.

Objective. To assess the clinical and microbiological response to a multiple drug regimen for disseminated MAI.
Methods. 17 AIDS pts. with sustained MAI bacteremia were treated with AMK (7.5mg/kg/day for first 4 wks.), CPF (750mg BID), ETH (15mg/kg/day), and RIF (10mg/kg/day) for at least 3 months. Median time since AIDS diagnosis was 21 wks (range 2-52) and since outset of possible MAI symptoms (see table) was 4 wks. (range 0-38).
Results. Log_{10} median colony forming units (CFU) fell by 1.2 (2.4→1.2) in 4 wks in concert with decreased prevalence of symptoms. Improvements were sustained thru 12 wks. in those who tolerated therapy. Treatment was terminated prematurely (<12 wks.) for nausea (4) and hepatitis (2).

WEEKS	0	4	8	12	>16
NUMBER OF PATIENTS	17	15	11	10	6
MEDIAN CFU./ML (LOG_{10})	2.4	1.2	1.3	1.2	0.2
FEVER %	94	27	36	30	71
WEIGHT LOSS %	88	53	45	60	57
NIGHT SWEATS %	82	40	18	10	29
DIARRHEA %	41	27	18	40	57

Conclusion. This regimen relieves symptoms and reduces bacteremia in a majority of patients, but has significant toxicity, requires parenteral administration, and does not frequently terminate bacteremia.

Programmes de soins infirmiers : éducation
Nursing Health Care Programmes: Education

M.B.P.301 PATIENT COMPLIANCE AND TERMINATION IN COMMUNITY-BASED CLINICAL TRIALS OF AIDS TREATMENT.

Holzemer, Stephen P.; and Seeman, J.D. Community Research Initiative, New York, NY, U.S.A.

Objective. To present an analysis of data concerning participant compliance and termination in clinical trials.
Methods. We analyzed drop-out rates for participants enrolled in clinical trials carried out in the past year by the Community Research Initiative. We also estimated the effect of certain interventions designed to diminish drop-out rate.
Results. Of 260 participants in two trials over a one-year period, 60% remain in the trial. Reasons for termination include death, intercurrent illness, voluntary withdrawal, and noncompliance. We estimate that in the latter two categories, a 25% greater drop-out rate would have occurred were it not for our initiation of at-home and in-hospital visits to provide treatment, and initiation of telephone counselling and on-site supportive intervention to participants and to their lay care-givers.
Conclusion. A high drop-out rate should be anticipated in clinical trials involving persons with AIDS/ARC. It can be compensated for by increasing the number of participants, and by augmenting personnel to provide aggressive case-management, as illustrated.

M.B.P.302 CLINICAL IMPACT OF CASE MANAGEMENT BY AN INPATIENT AIDS CLINICAL NURSE SPECIALIST ON COSTS AND QUALITY OF PATIENT CARE

Diane E. Schull, Parkland Memorial Hospital, Dallas, Texas, USA.

Objective: To study the effects of an inpatient AIDS Clinical Nurse Specialist and case management practice on costs, clinical outcomes and quality of patient care.
Methods: The patient populations used in this study were those inpatient admissions in 1988, 1987, 1986 and documented as HIV+, ARC, or AIDS. Data was analyzed for two (2) time periods related to the appointment of an inpatient-based Clinical Nurse Specialist (CNS) in 1988. Case management included the identification and classification of each patient and upon admission, daily patient contact and anticipatory and comprehensive planning during each phase of the patient's illness. The case management protocol extended beyond hospitalization to include discharge and follow-up into the outpatient AIDS clinic. Average length of stay (LOS) and readmissions were the indexes used to evaluate cost-effectiveness and quality of care respectively.
Results:

Group I: 1986	Group II: 1987	Group III: Oct.-Dec. 1988	
n = 191	n = 331	n = 150	
LOS 11.66	LOS 11.51	LOS 9.03	p = < 0.05*
readmission 31%	readmission 33%	readmission 11%	p = < 0.05*

* chi square analysis

The average LOS was 11.66 days in 1986 and 11.51 days in 1987. With the involvement of an inpatient-based AIDS Clinical Nurse Specialist, the average LOS was decreased to 9.03 days. The percentage of readmissions to the institution was 31% in 1986 and 33% in 1987, and similarly fell to 11% in 1988.
Conclusion: The results of this study indicate that LOS and readmission rates are significantly reduced by the role of an inpatient-based CNS and case management.

M.B.P.303 THE ROLE OF NURSING IN MANAGING COMMUNITY-BASED RESEARCH

Holzemer, Stephen P.; Tomita, M.; Forrest, J.; Bennett, J.; and Scherer, P. Community Research Initiative (CRI) New York. NY, U.S.A.

Objective. To describe problems encountered and resolutions developed in management of community-based research from a nursing perspective.
Methods. Identification of problems and resolutions in the following categories: protocol development and implementation, data collection, quality assurance, budgeting for research, case-management in recruitment and retention of research subjects, and personnel management.
Results. The New York CRI is the first free-standing, community-based research organization in the USA. The CRI-model has created methods of managing clinical research trials from a community perspective. The CRI-model has been developed with clinical nurses assuming a major role in management of clinical trials.
Conclusion. Using clinical research nurses to manage clinical trials provides one approach to successful operation of community-based research. Our experience should be of value to those planning or implementing a community-based research model.

M.B.P.304 NURSING IN THE COMMUNITY FOR PEOPLE WITH HIV: DESCRIPTION OF A TRAINING/IMPLEMENTATION PROGRAMME

Kirsch, Gorm*; Moore, H.**; Mayon-White, R**; Klimes, I**

*Oxford Regional Health Authority, Oxford, UK, **Oxfordshire Health Authority, Oxford, UK.

Objective. To develop and implement a training programme to ensure the most effective utilization of community nursing services by people with HIV infection and disease.
Methods. Experience in Oxfordshire of working with HIV disease was confined mostly to acute sector staff, thus blocking the full utilization of community care by people with HIV. Integration of HIV care into community nursing services was achieved by developing a facility whereby one community nurse from each population-based geographical sector was released for training and work on the in-patient wards.
Results. Nurses were able to facilitate the care at home of patients through liaison between hospital and local primary health care (PHC) teams, and by sharing knowledge and experience with colleagues. The programme was implemneted by identifying staff, devising a training curriculum and providing the policy and resource back up which was necessary. These processes will be fully described in the presentation.
Conclusion. Care in the community must be actively developed. The specialization of services in the acute sector reduces the care options for the patient. Such development is most effective when implemented through the PHC team setting in the community.

M.B.P.305 PROJECTIVE REPORT ABOUT SELF, FAMILY, ENVIRONMENT AND DISCOMFORT ASSOCIATED WITH SYMPTOMATIC HUMAN IMMUNODEFICIENCY VIRUS INFECTION IN CHILDREN.

Schwartz, P., Carter, Susan, Raburn, T., and Hanson, I.
Baylor College of Medicine/Texas Children's Hospital, Houston, Texas.

Objective. To demonstrate that the child with AIDS and symptomatic HIV infection can describe the progression of physical discomfort through the use of colors, body outline drawings, and visual analog.
Methods. Projective drawings and visual analogs are solicited monthly over a 2 year period while children are outpatients at a hospital clinic. Drawings are analyzed using standard analysis guidelines for children's art. Visual analogs (facial scales) are analyzed on the interval level comparing parent and medical report of the child's health to the scores on the scale.
Results. Preliminary results on 8 children over an 11 month period indicate that children can pinpoint in drawings sites of physical discomfort, as well as sources of psychological distress. The 3 children with stable family lives indicate varying degrees of physical discomfort through their drawings, but depict happy self, family, and environment, thus showing a relatively low visual analog score (the lower the score, the "happier" the child). The 5 other children with less stable home environments and/or behavioral disorders have higher visual analog scores.
Conclusion. Preliminary results indicate that communication through art work can be constructive and predictive in children who may not be able to communicate their feelings verbally. These drawings are also helpful in determining sites of discomfort, therefore enhancing healthcare.

M.B.P.306 INFECTION CONTROL NURSE ROLE: POWERFUL CHANGE AGENT IN PSYCHIATRIC SYSTEMS IN THE ERA OF AIDS

Sheila Dollard-Pavlis*, J. Gordon**, *Connecticut Mental Health Center, Yale-New Haven Medical Center, New Haven; **University of New Haven, West Haven, CT, U.S.A.

Objective. Because psychiatric units tend to stress psychosocial rather than medical aspects of care, practitioners in these settings are generally less comfortable with Infection Control (IC) procedures and are concerned about how these will adversely affect the established therapeutic milieu. The successful integration of AIDS patients on these units will depend on the Infection Control Nurses (ICN) ability to innovatively conceptualize the role as a key organizational change agent. Using a frame of reference common to psychiatric-mental health nursing (P-MHN) and sociology, attention is focused on the pivotal role of ICN in shaping organizational response to the first cohorts of HIV affected persons in psychiatric systems.
Mehtods. Relevant concepts are presented, drawn from data gathered from participant/non-participant observations, survey responses and informal interview of staff, patients and families. Confidentiality is maintained by presenting illustrative case material synthesized from published and unpublished sources.
Results. Given the anxiety AIDS engenders among psychiatric administrators and staff, the ICN is thrust into prominence and must shape policies and procedures that govern patient treatment and staff behaviors. In an atmosphere frequently fraught with tension and urgency, the ICN must rapidly develop a plan that maximizes administrative goals, facilitates treatment and protects patients, families and staff. Realization of these sometimes conflicting tasks will depend on the knowledge, sensitivity and abilities of the ICN whose active attitudes and personal attributes can create a hostile or therapeutic involvement.
Conclusions. The successful integration of AIDS patients on psychiatric units requires an ICN who attends to the interrelationships of biopsychosocial theories, research and practices. The ICN, who has a strong background in both IC and P-MHN can be a powerful positive influence and lend authenticity and acceptability to the IC policies and procedures in a psychiatric system.

M.B.P.307

HIV SELF ASSESSMENT AND CARE PROGRAM

Tom Emanuele, R.N., AIDS Nurse Clinician, AIDS Clinic, Parkland Memorial Hospital, Dallas, Texas, U.S.A.

OBJECTIVE: To develop a comprehensive program of preventative care services for eligible clients utilizing a Registered Nurse (R.N.) as a consistent primary caregiver.
METHOD: The client must first throughly understand what Human Immunodeficiency Virus (HIV) is and what it means to them. Secondly they must understand normal vs. abnormal in reference to their health status. Finally they must be taught how to assess themselves for any changes in their health status. The components of the program are HIV counseling according to C.D.C. standards, complete physical exam for HIV infection staging, and patient education to teach the client to perform self-exam to assess for changes from their baseline health status.

Eligibility criteria are ascertained by the R.N. Clinician, and are: HIV seropositivity, desire and mental ability to learn self-assessment. Projected outcomes include increase in client and staff satisfaction, reduction of morbid events, hospitalizations and need for emergency services, maintenance of wellness, independence and financial stability
CONCLUSION: This program allows for the earliest entry of the client into the healthcare network while allowing them to remain productive members of society through their self-care and physical status assessment.

M.B.P.308

OUTBREAK OF NORWEGIAN SCABIES AMONG HEALTH-CARE WORKERS

Kelly, Ann; Fry, C.
St. Stephen's Hospital, London, England.

Objective To control an atypical outbreak of Norwegian Scabies amongst patients who were immuno-suppressed on an Aids designated ward. Diagnosing and treating 40 health-care workers and their partners and close contacts. Preventing the spread to non-infected persons from one severely infestated patient.

Method

1) Diagnosing and surveillance of an outbreak of atypical Norwegian Scabies and identifying infected health-care workers and patients.
2) Co-ordinating the treatment by ensuring all ward personnel were contacted and treated simultaneously. One other patient was treated at the same time.
3) Continued surveillance until all personnel were asymptomatic.
4) Standards of the ward had to be maintained and ensure infected staff were not giving direct patient care.

Results

1) Effectively contained the outbreak.
2) Prevented spread to uninfected persons.
3) Maintained the high standards of nursing care on the ward.

Conclusion

1) When patients are seen with skin problems Norwegian Scabies may be considered, so outbreaks can be prevented.
2) Similar method of treatment recommended as it proved to be effective.
3) Health-care workers and patients followed up as re-infestation could re-occur.

M.B.P.309

DEVELOPING COMMUNITY NURSES SKILLS IN HIV/AIDS PROGRAMMES

*Snee Thomas, and Robottom B**, Pratt R***, Wills C*** Kuykendall J***, Newbury J***. *Department of Health, London England, UK and ***English National Board for Nursing, Midwifery and Health Visiting, London, England, UK. ***Riverside Health Authority, London, England, UK.

Objectives:- A Government initiative aimed at improving levels of understanding among community nurses of HIV infection and AIDS; to provide opportunities for them to examine personal attitudes which may be obstacles to effective care and preventative treatment; to encourage their participation in HIV programmes.

Methods:- Workshops of two day duration were held in 14 Health Regions in England to demonstrate dissemination of information by a cascade effect; between 20 and 40 senior nurse managers took part in each. Sessions were facilitated by a team experienced in the care of HIV infected people. On completion each participant was asked to list specific initiatives to be implemented locally. Six months later participants were followed-up to determine achievements, barriers encountered and possible solutions to them. An evaluation was made of the effectiveness of the Workshop with a view towards making recommendations on local and national policy.

Results:- Various initiatives set up demonstrated that Districts with low HIV prevalance encountered difficulties in sustaining the initiative. More enthusiastic follow-up was demonstrated in Districts with perceived growing AIDS caseloads. In all participants, levels of confidence improved.

Conclusions:- A method of initiating cascade communication is a beneficial method of using key people who, after analysing their own attitudes to the subject had sufficient influence to effect change.

M.B.P.310

TOTAL HOME HEALTH CARE FOR PATIENTS WITH HIV DISEASE

Carr, Susan E., RN, BSN; Esposito. Anthony J.
Windsor Home Care, Inc., New York, NY, U.S.A.

Objective: To develop and implement a program for the transfer of the comprehensive health care of the AIDS patient to the home setting providing a more desirable alternative to the costly hospital setting particularly in light of the shortage of beds in hospitals where AIDS is endemic.
Methods: Describe and implement a program which encompasses total health care services for the AIDS patient in the home setting.
Results: Program components developed and implemented are: 1) Physicians knowledgable & compassionate in the care of the AIDS patient with a sound belief level in home care as a viable alternative; 2) Nursing service case management & coordination focussed on the AIDS patient in complete collaboration with the physicians; the following services are necessary: a. Direct caregivers specially trained in the care of the AIDS patient with IV therapy and teaching programs for patients & family. A "wellness" program is inherent for sound health practice & counselling, b. Vendors to provide IV therapy pharmaceuticals & supplies, durable medical equipment, medical transport & lab services who are sensitive to the special needs of the AIDS patient, c. Therapeutic professionals such as SWs, PTs, OTs & STs to provide rehabilitative services & crisis intervention, d. Community support services for meal delivery, pet care & support groups for patient & family; 3) Health care cost payors with cost-effectiveness & compassion for the AIDS patients' preference for home health care; 4) Out-patient facilities to provide for necessary transfusions, invasive procedures & testing. In 1988, 350 patients have been provided with this type of care in the NYC metropolitan area.
Conclusion: AIDS patients can receive cost-effective, comprehensive, safe and compassionate home health care.

M.B.P.311

INTERDISCIPLINARY HIV CASE MANAGEMENT TEAM

Tom Emanuele, R.N., K. Joy, RN, BSN, L. McMurtry, MSSW, Parkland Memorial Hospital, Dallas, Texas, USA.

OBJECTIVE: To develop a system to coordinate appropriate home care services for Persons with AIDS (PWA's) within a model utilizing components from existing nursing process and social work case management models.
METHOD: Establishing a hospital-based case manager to assess patient needs and coordinate implementation of necessary medical and social services through regularly scheduled weekly networking case conferences. Collaboration of existing community-based AIDS service organizations involved with Parkland patients to provide needed hospital, clinic and community-based services.
RESULTS: By discussing spiritual, psychosocial and healthcare needs of 25-40 patients at each meeting and identifying actual and potential problems, group members discuss means of addressing them without duplicating efforts and providing for smooth transition for the client from hospital to home or clinic to home. With few exceptions the team can assure discharge to home for our patients.
CONCLUSION: Networking has made it possible to start discharge planning on admission and as a result, decrease length of stay. The team now has the flexibility to quickly respond when healthcare outcomes do not meet expectations.

M.B.P.312

A DESCRIPTION OF NYC'S GAY POPULATION AS A LEGITIMATE COMMUNITY: AND IT'S RESPONSE TO HIV DISEASE.

Smith, Donald G.*; Lyden, M.**; May, K.***
*Mount Sinai Medical Center, New York, New York, USA, **New York University Medical Center, New York, New York, USA, ***University of Arizona, Tucson, Arizona USA.

Objective. (1)To describe and evaluate the NYC gay population as a legitimate community by standard definitions. (2)To perform a nursing assessment on the affect of HIV disease on the community and recommend nursing interventions.
Methods. A needs assessment was performed by interviews with groups representing the community; ie. NYC's Office of Gay and Lesbian Health Concerns, interviews of NYC gay males and a literature review of published studies on AIDS within the community.
Results. The NYC gay population identifies themselves as a community and meets current definitions of community. The assessment showed direct affect on the community. It identified goals for the community's health: (1)Return of the community to a state of health. (2)To prevent an increase of the number of AIDS cases within the community. (3) To reduce the number of other STD's.
Conclusion. We identified a community, who's health is in crisis. It has identified it's own goals on returning to health, and developed a response through community involvement. We identified ways Community Health nurses can assist the community in it's return to health, by developing nursing programs to support the Person with AIDS. (2)By supporting community educational programs on prevention. (3)Planning additional resources for the community.

M.B.P.313 LOS ANGELES PEDIATRIC AIDS NETWORK (LAPAN): A COUNTY-WIDE MODEL TO MAXIMIZE SERVICE DELIVERY FOR CHILDREN DIAGNOSED WITH HIV, AND THEIR FAMILIES.

Garell, D.C., Kaplan, Marcy E., California Children Services, Los Angeles California, USA.

Objective: To promote interagency collaboration and facilitate effective service provision to children with HIV and their families. This project addresses current and future resource needs, clinical case management of all HIV patients, and social service concerns. Methods: Hospitals and community-based organizations (CBO's) were brought together to form the LAPAN Coordinating Council. An automated case management system is being developed to facilitate communication, create a common data base and use of CBO's. Terminals will be placed and social workers assigned at 7 participating hospitals. A formal needs assessment has been completed. Joint collaboration has also been established with staff from an NIH-funded treatment grant and a CDC Pediatric Surveillance Grant. LAPAN has also established a Consortium (LAPAC) to increase communication and exchange ideas amongst front-line professionals providing direct service. Results: The demonstration project has developed an automated case management system, methods to prevent duplication of service delivery, and has enhanced utilization. Conclusions: The creation of an infrastructure to manage pediatric HIV cases in Los Angeles is critical. Multiple use of resources and joint planning has been essential to meet the needs of this multi-problem population.

Supported by MCH grant #BRH PO 9001-01-0.

M.B.P.314 THE DEVELOPMENT OF A PRENATAL-PEDIATRIC AIDS LIASON SERVICE AT A MUNICIPAL HOSPITAL

Laqueur, Peter, Urcuyo L., Tropnas J., Grier P., Abisogun B., Watts L. - Woodhull Medical & Mental Health Center, Brooklyn, NY, USA.

Objective. To describe the development of a unique Prenatal-Pediatric AIDS Liason Service at a municipal hospital.
Methods and Results. Woodhull Medical & Mental Health Center, a division of NYC Health and Hospitals Corporation, is a large municipal hospital serving an impoverished black and latino community with a high incidence of IVDU and a high seroprevelenc rate for HIV. Increased outreach, counselling and testing, specifically targetted to women and children at risk for HIV-associated illnesses, has resulted in the need for a comprehensive, interdisciplinary approach to perinatal HIV infection. The Prenatal-Pediatric AIDS Liason Service (P-PALS), funded through the NYC Department of Mental Health, was developed to provide the necessary linkages between the Departments of Obstetrics, Pediatrics, Psychiatry, Medicine and Ambulatory Care to provide a family-oriented approach which optimizes continuity of care. The focus of the program is to assist the HIV positive pregnant woman and her family in coping with the possibility that her infant may be born HIV positive and to provide ongoing social, psychiatric and medical care for families who have children with HIV associated illness. The professional staff is comprised of a team which includes a child psychiatrist, social worker, nurse clinician and child life worker. Issues of foster care placement will also be highlighted.
Conclusion. Unified early intervention will improve the care of the woman and her child, diminish the need for long term placement, and provide a model of care based on the family rather than focussing individually on the mother and child.

M.B.P.315 COMPREHENSIVE CARE PROGRAM FOR CHILDREN WITH HIV-RELATED PROBLEMS AND THEIR CARE GIVERS

Read, Stanley, King, S.M., Arneson, C., Palmer, S., Goldie, R., Szewczyk, L., Lefebvre, A., et al. Hospital for Sick Children, Toronto, Canada.

Objectives: To provide comprehensive medical, social and psychological care and support for children with HIV-related problems and their care givers.
Methods: HIV positive children and their care givers are followed by a team of medical specialists, along with team members from nursing, psychology, psychiatry, social work, clinical nutrition, pharmacy, pastoral care and Childrens Aid. Three comprehensive care programs are coordinated to provide optimal care. These include the Hemophilia Comprehensive Care Program, the Adolescent Medicine Program and the HIV Comprehensive Care Program. Psychiatric involvement emphasizes development of coping mechanisms for dealing with stress. Serial psychometric testing is done.
Results: To date, about 50 HIV-positive children are followed by the combined programs. Of these, 35 are children with hemophilia, 5 are neonatal transmissions, 5 are blood transfusion recipients and 5 are adolescent street prostitutes.
Conclusion: An integrated program combining medical, psychologic and social services provides optimal care for children with HIV infection and their care givers.

M.B.P.316 LES SOINS INFIRMIERS FACE A L'EPIDEMIE DE SIDA

Schneeberger, Claudie. Val de Marne, France.

Devant la complexité de cette épidémie, dégager les différents rôle de l'infirmière en matière de soins infirmiers:

Dans L'accueil et la prise en charge des malades atteints du SIDA, l'accompagnement tout au long de la maladie et dans les derniers instants de la vie en organisant les mesures préventives permettant une plus grande sécurité dans les gestes techniques des soignants.

En développant une attitude professionnelle appropriée respectant l'homme dans ses différences lui assurant la confidentialité et préservant sa dignité.

Dans le cadre des actions de prévention la responsabilité de l'infirmière dans la participation aux programmes d'information de la population pour apprendre à éviter le SIDA.

Son rôle dans l'éducation pour modifier les habitudes les plus intimes et conduire chaque personne vers une gestion globale de sa santé en développant des attitudes responsables.

M.B.P.317 THE EFFECTIVENESS AND FEASIBILITY OF HOSPITAL-BASED SUPPORT GROUP INTERVENTION FOR PARENTS OF HIV-INFECTED CHILDREN

Kaplan, Marcy E., Church, J.A., Mitsuhata, K.T.; Childrens Hospital of Los Angeles (CHLA), Los Angeles, California, USA.

Objective: To evaluate the effectiveness of a support group for parents of HIV-infected children. Methods: 21 group members were recruited from the Clinical Immunology Center at CHLA and other referral agencies in Los Angeles. HIV status of children varied from asymptomatic to full-blown AIDS. Mode of transmission included blood transfusion (15) and perinatal (6). Group met bi-weekly from 1/87 through 8/88. Results: During the first six months, attendance ranged from 7-11 participants; all had children with treatment-associated HIV. 24 parents elected not to attend the group, citing feelings of increased stigma and isolation. Others discontinued participation citing depression and anxiety induced by clinical problems described in other participant's children. As the proportion of perinatal cases increased, participation in group declined. Conclusions: Ongoing group support intervention for parents with HIV-infected children resulted in unexpected difficulties. Dysfunctional families are additionally burdened by the ramifications of HIV in multiple family members. Support group attendance may not be a priority. Alternative support services must be developed to meet the needs of this multi-problem population.

Supported by the State of California, administered by the Department of Health Services, Los Angeles County AIDS Program Office.

M.B.P.318 HIV AND MATERNAL CHILD HEALTH: EXPANDING THE EXPERTISE AMONG PROVIDERS

Pies, C.*; Quackenbush, Marcia**; Melia, E.***; Horton, A.***; Schuyler, M.****; Mayes, A.***

* Education Program Associates, Campbell CA; **University of California AIDS Health Project, San Francisco; ***California Department of Health Services, Maternal Child Health Branch; ****California Department of Health Services, Office of AIDS, California, U.S.A.

Objective. To describe a training program which seeks to expand HIV expertise among non-physician health providers in maternal child health (MCH).

Methods. In California, 150 contract agencies throughout the state provide maternal child health care with the support of the State Department of Health Services. These programs include prenatal health care, follow up for high risk and addicted infants, care for disabled or delayed children, health care and parenting education for teen parents, etc. However, many MCH providers in the state feel that HIV expertise rests primarily with a few specialists in major urban areas (San Francisco and Los Angeles). This presentation will describe rationales for expanding HIV expertise to maternal child health providers throughout the state and discuss a specific training protocol designed to help accomplish this goal.

Results. Five two-day trainings will be held throughout the state by May 30, 1989. We will offer preliminary evaluation of the program's success. The complete training manual will be available for review.

Conclusions. A training program for maternal child health providers can expand HIV expertise to individuals and areas that are not currently confident of their ability to provide such care.

Supported in part by a grant from the California State Office of AIDS, contract # 88-94560.

M.B.P.319 A COMPARISON OF HEALTH CARE DELIVERED TO PEOPLE WITH AIDS AND ARC BY A NURSE PRACTITIONER AND A PHYSICIAN-A CASE MATCHED RETROSPECTIVE STUDY

Wolbert, Jerry; Rogers,P.; Keyes,C.; Marte,C.; Smothers,K.
Bellevue Hospital Center/Community Health Project, AIDS Assessment Program
New York, New York, USA.

OBJECTIVE: To compare health care delivered to people with AIDS and ARC by a Nurse Practitioner (NP) and a Physician (MD).
METHODS: A retrospective study was conducted on 22 AIDS and ARC patients randomly assigned to an NP and an MD for health care in an outpatient clinic. All subjects were gay men on Zidovudine for one year or longer.
RESULTS: Each sample consisted of 7 men with AIDS and 4 with ARC. The MD group had 2 with KS at the onset compared with 4 in the NP group.

	months in study	# of visits	initial T4#	changes in T4#	changes in WBC	changes in Hct	changes in weight	serious OI's	hospital-izations
MD	14.09	11.2	176	-62	-.55	-1.61	-5.85 lbs	4	5
NP	14.5	14.8	141	-45	-.96	-3.08	-5.18 lbs	4	4

NP subjects were followed longer and seen more frequently. Initial T4 values were similar as were changes in blood parameters. Hct differences were affected by transfusions(11 by MD, 0 by NP). The groups were remarkably similar in the number of HIV related hospitalizations and serious OI's.
CONCLUSION: A Nurse Practitioner can provide health care to people with AIDS and ARC, equal in quality and safety, to that of a Physician in an outpatient setting.

M.B.P.320 SURVEY OF TENNESSEE NURSES ATTITUDES TOWARD AIDS

Monnig, Regina* and Harris, V.*
*Meharry Medical College/ECAETC, Nashville, TN, U.S.A.

Objective. To describe knowledge and attitudes of nurses regarding AIDS.
Methods. The survey contained questions which focused on respondents' perceptions of their needs for information about AIDS/HIV, treatment, risk factors, referral sources, and learning modalities.
Results. Most nurses (N314) would assist in treatment of HIV-positive patients. Nurses tended to refer patients to public health departments and social workers for counseling. Nurses usually obtained information regarding AIDS from journals and conferences. Only about one half of the nurses were satisfied with their current level of knowledge of AIDS.
Conclusion. The survey provided useful information in the development of training materials and programs for nurses.

M.B.P.321 GAY GRIEF IN THE CONTEXT OF AIDS

Helgadottir, Hildur. University of Calgary, Calgary, Alberta, Canada.

Objective. To examine the biopsychosocial phenomenon of gay grief in the context of AIDS, as well as explore nursing interventions pertinent to this topic.
Methods. The topic is approached from a theoretical perspective, using the relevant literature on homosexuality and grief in combination with the author's own observations and conceptualisations. Gay grief is defined as the grief experienced by homosexual individuals who lose a significant other. For the purposes of this paper this definition is narrowed further to include only homosexual men who have lost a lover to AIDS. The purpose of the discussion is to sensitize the audience to this important phenomenon by comparing and contrasting conventional grief theories to the unique issues faced by bereaved lovers of AIDS patients. In light of the physical, psychological and social issues brought to light by the AIDS crisis, nurses need to be aware of variables interfering with normal, healthy grief reactions within this clientele. The detrimental effects of bereavement on the immune system are discussed as well as the possible role intense grief can play in the onset of AIDS in the HIV seropositive individual.
Results. A conceptual framework for looking at grief and bereavement in lovers of AIDS patients is presented as a tool for understanding gay grief and guiding nursing interventions.
Conclusion. Very little is as yet known about specific grief reactions in the homosexual community. This paper highlights some of the main issues.

M.B.P.322 PROVIDER EDUCATION: THE EFFECT OF AIDS INSERVICE TRAINING ON NURSING STAFF IN A PSYCHIATRIC SETTING.

Jacobs, Jonathan; Reid, P. Center for Special Studies, New York Hospital-Cornell Medical Center, New York, NY, USA

Objective: To decrease nurses AIDS related anxiety and improve AIDS education and counseling skills.
Methods: Fortyfive minute inservices were conducted for night nursing staff from four units in a psychiatric hospital. Nineteen nurses completed pre and post inservice surveys. The surveys measured the nurse's level of anxiety, comfort and knowledge concerning important issues in the care of patients with AIDS. The nurse's level of commitment to incorporating AIDS related issues in patient education was also measured.
Results: Survey results indicate a 16% increase in the maximum level (75-100 on a scale of 0-100) of commitment to incorporating safe sex and risk factors in patient education. Maximum comfort level increased 25% for discussing safe sex practices with patients and 10% for discussing risk factors. A 37% increase in maximum comfort level with knowledge of CDC defined AIDS, ARC and HIV positive was reported. A 43% increase in maximum comfort level with counseling HIV positive patients and a 16% increase in maximum comfort with counselling patients with AIDS was indicated. There was also a significant increase in the mean level of comfort in the previous categories. The survey indicated no significant change in anxiety concerning infection when working with patients with AIDS.
Conclusions: Inservice education for nurses caring for HIV infected patients can increase their commitment to AIDS related patient education as well as their comfort level with counseling patients and knowledge concerning AIDS related issues.

Thérapie et évaluation clinique : pharmacologie
Therapy and Clinical Evaluation: Pharmacology

M.B.P.323 PHARMACOKINETICS OF ZIDOVUDINE IN AIDS PATIENTS : INFLUENCE OF AGE AND HEPATIC DISORDERS

H.[illegible][1], F.[illegible][1], I.TABAH[1], B.RIO[1], J.J.[illegible][2], E.OKSENHENDLER[2], E.VILMER[3], F.CHAST[1].
1: Hôtel-Dieu, 2: Hôpital Saint-Louis, 3: Hôpital Robert Debré - PARIS , FRANCE.

Objective : Pharmacokinetics of Zidovudine was evaluated in 31 AIDS patients after oral chronic administration of 300 mg qid or 3 mg/kg qid in infants. Patients were divided into 4 groups : infants (6-12 months), adults (25-55 years), elderly (>60 years), and patients with hepatic disorders (HD).

Methods : Pharmacokinetic profiles were determinated at steady-state during 6 hours after drug administration. Plasma concentrations were determinated by reversed phase HPLC with spectrophotometric detection.

Results :

Mean ± SEM	Cmin ng/ml	Cmax ng/ml	Tmax min	T1/2 min	Clp ml/min	Vd l/kg
Infants	15 ± 3	1745 ± 285	30 ± 0	64.8 ± 2.4	288 ± 6	3.0 ± 0.3
Adults	65 ± 19	1773 ± 203	51 ± 7	85.2 ± 7.8	1561 ± 115	2.5 ± 0.3
Elderly	96 ± 36	2857 ± 1728	50 ± 21	129.6 ± 32.8	1035 ± 275	4.1 ± 2.4
H D	209 ± 81	2916 ± 1034	60 ± 19	109.2 ± 12.0	1203 ± 592	3.2 ± 1.4

Conclusion: Pharmacokinetic data obtained in infants validate the choosen dosage regimen. In elderly and in patients with hepatic disorders, kinetic parameters show a noticeable decrease of zidovudine elimination rate. High peak and trough plasma concentrations may indicate toxic drug accumulation. We suggest, in these high-risk patients, to lengthen the time interval between dose intake.

M.B.P.324 EVALUATION OF LESS FREQUENT ZIDOVUDINE DOSING IN CHILDREN WITH SYMPTOMATIC HIV INFECTION

Giaquinto Carlo*;Terragna A**;Plebani A***;Tovo P****;DeRossi A*;Dowd P ***** et al. *Univ.of Padova:**Inst.Gaslini,Genova:***Pediatrics Cl., Milano:****Pediatrics Cl.,Torino,Italy:*****Wellcome Research Laboratories,UK.

Objective: To evaluate the tolerance and pharmacokinetics of less frequent zidovudine dosing regimens in children with symptomatic HIV infection.
Method: In this ongoing phase 1 study children aged between 3 months and 6 years with symptomatic HIV infection but not AIDS, are being randomized to receive oral zidovudine at the following daily dosage: Group A - 600 mg/m^2, Group B - 720 mg/m^2.
For the first 4 weeks the zidovudine is administered in 4 equally divided doses. Thereafter the frequency of dosing is reduced to twice daily. the randomization is stratified according to age (3 months - 2 years and 2 years - 6 years). On days 0 (post dose 1), 28, 56 and 84 blood samples are being taken at regular times intervals for the assay of zidovudine levels.
The patients tolerance to therapy, clinical and virological status is being assessed at 2 weekly intervals.
Results: Fourteen children have been included, 8 older than 2 years (mean age 37.5 mo) and 6 younger (mean age 9.5 mo). All children fulfilled the laboratory criteria of HIV infection and were classified as falling into category P2A plus at least one other subgroup of the CDC classification of HIV in children. Six of the 14 children have received the twice daily dosage regimen for approximately one month without experiencing any adverse effects. To date the drug has been well tolerated and no dose modifications have been required.
Conclusions: The results of this study should indicate whether further evaluation of twice daily dosing in children is warranted.

M.B.P.325 CYANOCOBALAMIN (VITAMIN B_{12}) SUPPLEMENTATION DOES NOT PREVENT THE HEMATOLOGIC TOXICITY OF AZIDOTHYMIDINE (AZT)

McCutchan, J. Allen; Ballard, C.; Freeman, B.; Bartok, A.; and Richman, D.; and the California Collaborative Treatment Group, University of California, San Diego, USA.

Objective. AZT and B_{12} deficiency both produce macrocytic anemia. Low normal serum B_{12} levels (<400 pg/ml) are associated with increased risk of granulocytopenia in AIDS and ARC patients taking AZT. Accordingly, we conducted a controlled trial to see if monthly B_{12} injections could prevent hematologic toxicity from AZT.

Method. 172 AIDS and ARC patients with serum B_{12} levels >200 pg/ml who were beginning (128) or taking (44) AZT at standard doses (1-1.2 grams/day) were randomly assigned to receive either four monthly IM injections of 1 mg of B_{12} or no injections. Serum B_{12}, WBC, absolute neutrophil counts (ANC), hemoglobin (HGB) mean corpuscular volume (MCV), platelets (PLT) and, AZT dose were followed monthly for at least six months.

Results. Mean B_{12} levels were increased four weeks after the first injection and remained elevated compared to controls throughout the study. Although by chance B_{12} recipients had higher ANC levels than controls at entry (2887 vs 2477, p=.032), all subsequent means of ANC, WBC, HGB, MCV, and platelets were similar (p>.08 for all comparisons). No differences in AZT tolerance or transfusion requirements were found.

Conclusion. Four monthly IM injections of B_{12} sufficient to increase serum B_{12} levels did not reduce the hematologic toxicity of AZT given for currently licensed indications.

M.B.P.326 ZIDOVUDINE MYOPATHY-A PROSPECTIVE STUDY

Peters, Barry† Wilson, G*† Pinching, A. J†
Departments of *Clinical Immunology and **Chemical Pathology, St. Mary's Hospital Medical School, London, England.

Objective. To study the relationship between Zidovudine (AZT) administration, myopathy and creatine kinase (CK).

Methods. 102 AIDS patients were seen monthly and clinical features of myopathy were recorded, including myalgia, muscle fatigue, reduced power and muscle wasting. Monthly CK levels were estimated. 78 of the patients were on regular AZT (usual dose 1000-1200mg/day) and 33 of these had been treated for 300 days or more. 24 patients not on AZT were studied as a control group to deliniate other causes of CK rise.

Patient	Onset of Myopathy Days on AZT (x)	Onset of Rise in CK Days on AZT (y)	x-y (Days)
1	371	290	81
2	426	275	51
3	350	312	38
4	350	300	50
5	323	270	53
6	378	326	52
MEAN	366	312	54

Results. Myopathy was severe and disabling, mainly affecting the legs and was preceded by a rise in CK. CK continued to rise to very high levels (>1000IU/l) during treatment. Dose reduction was ineffective, but marked clinical recovery occurred within 2 months of stopping AZT; CK levels fell to normal within 4 weeks.

Conclusion. 1.Sustained rises in CK provide the first indication of Zidovudine myopathy, hence CK should be routinely performed.
2.Myopathy is a progressive disabling complication of Zidovudine therapy, occurring in 18% (6/33) of patients on long-term therapy (>300 days).

M.B.P.327 NON CONCLUSIVE RESULTS IN HIV WESTERN BLOT ANALYSIS OF MOZAMBICAN SERA.

C.Palha de Sousa, J.Barreto,F.de la Cruz,L.Barquet.
Immunology Laboratory, Instituto Nacional de Saude,Maputo,Mozambique.

Objective:To describe the pattern of reaction of Mozambican sera with non conclusive results on HIV Western Blot Analysis.

Methodology:Serum samples from urban general population, blood donors, AIDS suspected cases and war displaced population repeatedly reactives by ELISA for HIV1 and HIV 2 antibodies and with non conclusive results in Western Blot were classified in relation with their protein band reaction. Some of them were tested by different commercially available WB kits. The frequency of the different observed pattern of reactivities was estimated.

Results:The most frequent observed reactivity patterns were reaction with p 24 band for HIV 1 WB (38%) and p26 for HIV 2 WB (20.6%). However in HIV 2 WB, 10.9% of sera analysed showed reaction with p68,p56,p36,p26 and p16 without any reaction with glycoprotein bands. Non conclusive results were more frequently found in HIV 2 than in HIV 1 WB. Some non conclusive sera by LAV BLOT II when tested by HIV 2 Dupont de Nemours and HTLV-IV SBL Western Blots showed also non conclusive pattern of reactivity. Same happened when non conclusive sera by HIV 1 Bio-Rad WB were tested by HIV 1 Dupont de Nemours WB. Non conclusive results appeared in sera from all the studied population groups.

Conclusion:Appearence of non conclusive results in WB analysis of ELISA positive Mozambican sera seems to be independent of the reagents used and due to sera or individuals characteristics.

M.B.P.328 A STUDY OF THE SAFETY AND EFFICACY OF RECOMBINANT HUMAN ERYTHROPOIETIN (r-HuEPO) IN AIDS PATIENTS WITH ANEMIA INDUCED BY THEIR DISEASE AND ZIDOVUDINE (RETROVIR, AZT) THERAPY

Galpin, J.*; Thompkins, Jennifer*; Abels, R.**, Turpen, T.J.*
*Porton Medical Group, Sherman Oaks, CA;
**Ortho Pharmaceutical Corp., Raritan, New Jersey, USA.

Objective. To determine if anemic AIDS patients who are all on concomitant zidovudine therapy and are transfusion-dependent have any measurable change in their hematocrit, hemoglobin and reticulocyte count after treatment with r-HuEPO.

Methods.Nine evaluable subjects with a pretreatment hematocrit of 30% or less were treated with ascending doses of r-HuEPO up to 900 u/kg weekly for 24 weeks. Patients were on daily doses of zidovudine of 400 to 4200 mg. The hematocrit, hemoglobin and reticulocyte count were obtained on a weekly basis.

Results.All but one subject attained a hematocrit of 38-40% during the 24 week trial, becoming transfusion-independent.

Conclusions.r-HuEPO appears to be a possible adjunctive therapy for AIDS patients who are anemic due to their disease and zidovudine therapy. This durg merits further wide-scale clinical trials.

M.B.P.329 MYOPATHY ASSOCIATED WITH LONG-TERM ZIDOVUDINE THERAPY

Fischl, Margaret; Gagnon,S; Uttamchandani,R; Patrone-Reese, J; Dearmas,L; Tarras,S; and Bender,A. University of Miami School of Medicine, Miami, Florida, USA.

Objective. To evaluate the frequency and clinical presentation of myopathy associated with long-term zidovudine therapy.

Methods. Patients receiving zidovudine for >40 wks were assessed, using medical history, physical exam and blood tests. Patients identified with possible myopathy were further evaluated with EMG and muscle biopsy.

Results. 50 patients (33 AIDS,17 ARC) had received zidovudine for a mean of 73 wks (range 40-140 wks). 15 (30%) had myopathy as manifested by myalgias-80%, muscle wasting-93%, and rhabdomyolysis-7%. Muscle groups involved included proximal muscles in the lower extremities-100% and upper extremities-27%, and intercostal muscles-13%. Associated symptoms included arthralgias-47%, weight loss >4kg-93%, and paresthesias-40%. Blood tests included persistently elevated LDH (1.5-2X normal) and CPK (1.5-8X normal). EMG was consistent with myopathy. Muscle biopsy showed degenerated myofibers, rare microvacuolar changes, and mild inflammation. Myopathy occurred in 53% of ARC patients and 18% of AIDS patients. Onset was between 52-107 wks of therapy and in patients having received a mean cumulative dose of 600-800gms. 8 patients required drug interruption. Symptoms improved within 1-8 wks. LDH decreased in all patients by 8 wks and CPK in 87% of patients by 4 wks. 4/8 patients developed recurrent symptoms within 1 week of restarting zidovudine.

Conclusion. Myopathy is common in patients receiving long-term zidovudine. Proximal muscle wasting in the lower extremities was the most common finding. Increased LDH was an early indication of myopathy.

M.B.P.330 HIV ASSOCIATED MYOPATHY: FEATURES IN 21 PATIENTS AND ROLE OF AZT

Simpson, David; Wolfe, D., Farraye, J., Bender, A.
Mount Sinai Medical Center, New York,
New York, USA.

Objective. To describe the features of 21 patients with HIV-associated myopathy as well as the role of AZT in this disorder.

Methods. All patients were evaluated at Mount Sinai Hospital. Electrophysiological testing included nerve conduction studies and needle electromyography (EMG). Muscle biopsies were processed by light and electron microscopy, and viral localization performed with immunohistochemistry and in situ hybridization.

Results. 12 patients had AIDS, 4 had ARC, and 5 were asymptomatic HIV-seropositive. 5 had been diagnosed as AIDS Wasting Syndrome. All presented with proximal muscle weakness. Creatine kinase (CK) levels were elevated over a wide range (mean 1438 IU/L). EMG revealed myopathic motor units in all patients, with abnormal spontaneous activity in 17. Muscle biopsy findings in 20 patients included inflammatory or noninflammatory myofiber degeneration, nemaline rods, cytoplasmic bodies and vacuolization. 8 of 9 patients treated with corticosteroids improved. 10 patients had never been treated with AZT. Of 11 patients on AZT, the myopathy worsened after AZT withdrawal in 4, and 2 improved with its reinstitution.

Conclusion. Myopathy is associated with HIV infection, and may be misdiagnosed as AIDS Wasting Syndrome. Corticosteroid therapy is effective. In our series, AZT does not appear causally linked to this disorder.

M.B.P.331 SERUM LEVEL AND SERUM KINETIC OF ZIDOVUDINE: INVESTIGATION WITH A RADIOIMMUNOASSAY (RIA)

Köppen, Stefan*; Ruf, B.*; Pannhorst, J.** and Pohle, H.-D.*.
*II. Department of Internal Medicine and **Department of Nuclear Medicine, Rudolf Virchow University Hospital, Freie Universität, Berlin, FRG.

To evaluate serum levels and serum kinetics of Zidovudine (Azidothymidin, AZT) with different dosagne and dosage intervals, serum samples of patients who had Zidovudine treatment have been investigated retro- and prospectively. Analysis was performed with a radioimmunoassay (ZDV-Trac™ RIA).

Retrospectively 282 serum samples of 47 patients were examined. Blood samples have been obtained two hours after oral application. The mean Zidovudine concentration was 735 nmol/l, 1272 nmol/l, and 1387 nmol/l when dosages of 6 x 100 mg/d, 6 x 200 mg/d, and 6 x 300 mg/d were applied, respectively.

Prospectively, serum kinetics of Zidovudine has been investigated at start of therapy. Five hours after application of 100 or 200 mg Zidovudine, serum concentration has fallen below 130 nmol/l, being reported to be the minimal effective serum concentration. After application of 250, 300 and 500 mg, serum concentration have been below 130 mg after 6 hours.

The RIA was highly specific, no cross-reactivity and non-specific reactivity has been noted.

Zidovudine is an intracellular active compound. Therefore, serum levels are of limited value. After retrospective correlation with the outcome of patients, recommendations of dosage regimens atributable to serum levels are reasonable. In long dosage intervals, effective intracellular concentration may not be achieved.

M.B.P.332 PHARMACOKINETICS(PK) OF ZIDOVUDINE(ZDV) IN ADULT PATIENTS WITH HIV INFECTION AND HEPATIC DISEASE (HD)

Tartaglione, Teresa*; Opheim, K.*; van der Horst, C.**; Raasch, R.**; Cheeseman, S.*** and High, K..**; et al. *University of Washington, Seattle, WA, USA, **University of North Carolina, Chapel Hill, NC, USA, ***University of Massachusetts, Worcester, MA, USA.

Objective. To determine ZDV's PK in patients with HIV infection and HD.
Methods. In an ongoing study, patients were stratified into 5 categories of stable HD according to serum ALT (<5X to >30X normal), TBIL and PT. On sequential study days, each patient received a single dose each of ZDV 120 mg IV followed by ZDV 200 mg PO. Multiple blood samples were obtained. ZDV and GZDV conc. were determined by HPLC and analyzed using noncompartmental methods.
Results. Five patients (3 males, 2 females) with HD and ALT values between 1.5 to 10 X normal and normal TBIL and PT values have completed the study. ZDV/GZDV PK are presented below:

	IV		PO	
	ZDV	GZDV	ZDV	GZDV
C^{max} (ug/mL)	1.5 ± 0.5	1.5 ± 0.2	1.9 ± 0.3	5.4 ± 1.4
AUC (ug/mL x hr)	1.6 ± 0.5	2.8 ± 0.4	1.7 ± 0.1	7.9 ± 0.8
F (%)	---	---	0.7 ± 0.1	---
$t_{1/2}$ (hr)	1.6 ± 0.3	1.9 ± 0.7	1.7 ± 0.5	1.4 ± 0.2
Vdss (L/kg)	1.8 ± 0.8	---	2.1 ± 1.0	---
TBC (L/hr/kg)	1.1 ± 0.4	---	1.3 ± 0.3	---

Conclusion: Preliminary ZDV and GZDV PK data in patients with mild HD is similar to previously reported data in patients with normal renal and hepatic function. Patients with moderate and advanced HD are under study.

M.B.P.333 ASSESSMENT BY PCR OF HIV-1 ACTIVITY IN AIDS-KS PATIENTS TREATED WITH RECOMBINANT INTERFERON ALPHA (r-IFNa)

Epstein, Jay S.*, Hewlett, I.K.*, Metcalfe, J.**, Hawthorne, C.*, Lane, H.C.**.
*Division of Blood and Blood Products, FDA and **Clinical Center, NIH, Bethesda, MD

Objective. To evaluate the effect of r-IFNa on HIV-1 replication in AIDS.
Methods. Eight patients with AIDS-KS receiving daily injections of r-IFNa (Schering) for therapy of KS tumors were studied multiple times over 1 to 2 years for serum levels of HIV-1 antigen (Ag), reverse transcriptase activity (RTA), and gene detection by PCR. PCR was performed on extracted DNA using simultaneous amplification of GAG and ENV sequences followed by selective hybridization with the respective probes .
Results. Five of 8 cases were tumor responders; 4 complete, 1 partial. Prior to therapy, PCR and RTA were positive in all eight cases, and Ag was found in 7 cases (1 tumor nonresponder was persistently negative). Antigen or RTA levels decreased in 5/5 tumor responders (2 Ag, 2 RTA, 1 both). In 1 nonresponder, viral DNA became undetectable despite persisting antigen.
Conclusion. r-IFNa produced decreases in activity of HIV-1 in 6/8 AIDS-KS patients including all 5 cases with tumor responses, but in no case was the decrease shown by all virologic parameters. PCR detection of viral DNA revealed persisting virus activity despite clearance of antigen and RTA. Future drug trials should include monitoring of HIV-1 activity by serum PCR.

M.B.P.334 BAYESIAN ESTIMATION OF THE PHARMACOKINETIC PARAMETERS OF CHRONIC ZIDOVUDINE (ZDV) THERAPY IN HIV INFECTED PATIENTS.

Janice Y.Tam[1], B.Joseph Guglielmo[1], Harry Hollander[2], and H. Mohammed[1].School of Pharmacy[1], Medicine[2], Univ of Calif.,San Francisco, CA, USA.

Objective To determine whether the individual pharmacokinetic parameters of ZDV can be estimated by Bayesian approach from data collected during multiple routine clinic visits in HIV infected patients.
Methods Eighty patients with AIDS or ARC receiving oral ZDV therapy at the AIDS Clinic of the UCSF Medical Center were recruited.On the morning prior to each routine clinic visit,the subjects recorded the dose and exact time of taking the last two doses of ZDV.During the clinic visit,an additional plasma sample was drawn at the time of routine blood sampling.This procedure was repeated for four clinic visits.Plasma ZDV levels were assayed by HPLC.The plasma concentration-time data was analysed by Bayesian analysis using TDMS^{R} and Drugcalc^{R}.
Results Preliminary results indicate a mean terminal half-life of 1.33±0.39 hours,an average bioavailability of 50.4±13.8%,a total body clearance of 1.04±0.13L/hr and a volume of distribution of 1.94±0.44L/kg.
Conclusions Results are in aggreement with literature data.Our results using population pharmacokinetics suggest that the pharmacokinetic disposition of ZDV is unchanged within HIV infected patients on chronic ZDV therapy.

M.B.P.335 EFFECT OF ZIDOVUDINE WITH PHASE I AND II METABOLISM IN THE LIVER

N. H. Brockmeyer, L. Mertins, M. Goos, University of Essen, Essen, Federal Republic of Germany.

The nucleoside analogue zidovudine is being employed in the therapy of HIV-infected subjects. The effect of zidovudine on the liver metabolism is of utmost interest. We chose 9 subjects not receiving any supplementary medication and we measured the parameters of the liver microsomal enzyme activity (antipyrine elimination incl. metabolite excretion and 6-beta-OH-cortisol in urine) before intake of zidovudine 800mg/day as well as after a treatment period of 14 days. Antipyrine and its metabolites were determined by HPLC. Following a two-week intake of zidovudine an induction of the microsomal enzyme system was observed, the excretion of 6-beta-OH-cortisol increased sigificantly from 342 to 697 g/24 hours. The half-life of antipyrine decreased from 12.2 to 10.1 hours. Contrariliy, the phase-2-metabolisation of the antipyrine metabolites nora-and 4-OH-antipyrine were significantly lower. These altered from 8.32 to 6.29 ml/min. and from 12.4 to 9.6 ml/min., respectively. This effect by zidovudine seems almost exclusively due to the inhibition of the glucoronism in the liver. The clearance to metabolite of the glucurinised nor-antipyrine and of 4-OH-antipyrine decreased by 18 and 29%, respectively.
On grounds of these results, clear interaction will occur during the simultaneous application of zidovudine with other drugs metabolised by phases I and II liver metabolism.

M.B.P.336 ZIDOVUDINE LEVELS IN AIDS AND ARC:VIROLOGIC AND HAEMATOLOGIC EFFECTS

Uberti-Foppa C.,Lazzarin A.,Ronchi P.,Cinque P.,Reale M.T
Clinic of Infectious Diseases, University of Milan,Italy.

Objective. To evaluate virologic and haematologic effects of different concentrations of zidovudine (ZDV) in p24 antigen and reverse transcriptase (RT) positive ARC and AIDS patients.
Methods. Six AIDS and two ARC subjects received ZDV(10 mg/kg q4h for 4 weeks, followed by 5 mg/kg q4h for 5 months). RT from lymphocytes and p24 antigen (EIA DuPont)were detected monthly. ZDV levels were evaluated (RIA,ZDVTRAC,Incstar) on day 10 and 60 at 0,30,60 minutes after oral administration.

Results.	p24 POS	RT POS
-month 0	8/8 (100%)	8/8 (100%)
-month 2	0/8 (0%)	3/8 (37%)
-month 6	3/8 (37%)	5/8 (62%)

	Mean ZDV levels(μmol/L)		
	0 min	30 min	60 min
-day 10	0.3	10.6	8.7
-day 60	0.3	4.8	3.3

Subjects with mild hepatic impairment(ALT<3 times upper normal values)had a high peak concentration(10 μmol/L)longer than other patients.
Conclusion. A)Dose of 5 mg/kg is sufficient to obtain a mean concentration of the drug 2 to 3 times above the "in vitro" minimum inhibitory dose for HIV-1. B)In hepatopatic patients with normal ZDV levels, the prolungation of peak concentration is sufficient to induce anaemia. C)At the evaluated doses, ZDV can reduce virus replication(shown by negative antigenaemia), but doesn't inhibit it completely.

M.B.P.337 A PRELIMINARY STUDY OF SERUM AZT LEVELS IN HIV-INFECTED INDIVIDUALS

Steffe, Erika*; Flynn, N.*; King, J.*; Batra, K.*; Tonjes, T.*; Winship, A.*; et. al.
*University of California, Davis, California, USA.

Objective. To determine whether serum AZT levels correlate with clinical efficacy and/or toxicity, and whether acetaminophen (A) effects serum AZT levels.
Methods. We measured serum AZT levels in 10 patients receiving varying oral doses, of whom 3 had rises in CD_4 from a mean of 327 to 535; 3 had no change in CD_4, and 4 had a decline in CD_4. One patient had clinical improvement, 3 had definite toxicity from AZT. Trough levels were drawn just prior to the AZT dose, and peaks were drawn at 1 and 2 hours post dose. Three patients were given A (650 mg q 6 hrs x 48 hrs) and levels were rechecked. Levels were measured by both RIA and HPLC methods.
Results. Mean peak levels (532 ng/ml) in patients taking 1200 mg of AZT per day correlated with dose. A did not affect peak or trough levels of AZT at the dosage of A used. Toxicity does not appear to be related to serum AZT levels in this small study population. In one patient with underlying bone marrow injury, 100 mg of AZT q 12 hrs produced profound red cell toxicity (peak 224, trough 39 ug/ul)
Conclusion. A longer study which correlates serum and intracellular AZT and GAZT peak and trough levels with measures of efficacy (CD_4, p24 antigen, B-2 microglobulin and clinical improvement) and toxicity (anemia, granulocytopenia, myositis, neuropathy) may give important information about AZT in treatment of HIV infection.

M.B.P.338 INTERACTIVE PHARMACOKINETICS OF ZIDOVUDINE AND ACETAMINOPHEN

Pazin, George J, Ptachcinski RJ, Sheehan M. and Ho M.
Pittsburgh AIDS Clinical Trials Unit, University of Pittsburgh, Pittsburgh, Pennsylvania U.S.A.

Objective. Since both Zidovudine (ZDV, Retrovir) and acetaminophen (Tylenol) are metabolized by hepatic conjugation, competition for conjugating enzymes may result in reduced elimination of either or both agents with a potential for increased toxicity. This study was done to evaluate the potential interaction between ZDV and acetaminophen.
Methods. Pharmacokinetics of ZDV after IV administration (2.5 mg/kg) was studied in 7 HIV-infected persons with normal renal and hepatic function after 3 days of maintenance oral ZDV (100-200 mg q4h) and with acetaminophen after 3 days of both ZDV and acetaminophen (650 mg q6h). Multiple blood and urine samples were collected over 48 hrs following the IV dose of ZDV. Serum samples were heated (56° C) for 35 min then extracted with a C18 solid phase column. ZDV was quantitated by HPLC. Serum concentration versus time data were analyzed using compartmental and non-compartmental methods.

Results.	ZDV alone	ZDV+Tylenol	p value
ZDV clearances (ml/min/kg)	19.4 ± 2.9	20.4 ± 4.0	> 0.05
mean term. disposition rate cons. (hr^{-1})	0.53	0.63	> 0.05
vol. of distribution (1/kg)	1.27 ± 0.35	1.24 ± 0.27	> 0.05

Conclusions. Our study indicates that acetaminophen does NOT effect the distribution or elimination of ZDV.

M.B.P.339 A SENSITIVE AND SPECIFIC HPLC METHOD FOR THE DETERMINATION OF ZIDOVUDINE AND ZIDOVUDINE GLUCURONIDE IN PLASMA AND URINE.

Hedaya, Mohsen A. and Sawchuk, R.J.
University of Minnesota, Minneapolis, Minnesota, USA.

Objective. To develop a sensitive and specific HPLC method for the determination of zidovudine (AZT) and zidovudine glucuronide (GAZT) in plasma and urine.
Methods. The method involves the use of double internal standards, allowing reference of AZT peaks to the appropriate internal standard, the choice depending on the range of concentrations encountered. Free (unconjugated) AZT is quantified by extraction with 5% isopropyl alcohol in chloroform. Total (conjugated and unconjugated) AZT is quantified by incubating the samples with bacterial β-glucuronidase and phosphate buffer at PH 6.8 for 4 hours at 37 °C. The samples are then extracted as described for free AZT. GAZT concentrations are calculated by difference, corrected for GAZT MW. The mobile phase consists of 9% acetonitrile in monobasic ammonium phosphate. We used a C_{18} column, and UV detection at 266 nm.
Results. The coefficient of variation of the between-run and within-run assay precision is < 10 % and the coefficient of variation of the assay accuracy determined from the analysis of quality control samples is also < 10 %. We saw no interference from various over-the-counter and prescription drugs often used in treating the infectious complications of AIDS.
Conclusion. Using this method we are able to quantify AZT and GAZT in human plasma and urine samples obtained over a 12-hour period after a single oral dose of 200 mg of AZT.

M.B.P.340 PHARMACOKINETICS OF AZT AMONG HIV INFECTED PATIENTS TREATED BY ITRACONAZOLE.

Henrivaux, Ph.; Fairon, Y. and Fillet, G.
CHU-Sart Tilman, State University of Liege, Belgium.

Objective. Symptomatic HIV infected patients are frequently submitted to Azidothymidine (AZT) therapy in association with antibiotics and/or antimycotics. We were interested to investigate the pharmacokinetic properties of AZT during the administration of Itraconazole, a new antimycotic compound.
Methods. Seven patients (5 patients CDC 4C2 and 2 patients CDC 4C1), regularly treated by AZT for 48 ± 4.5 weeks at the dose of 3 ± 0.1 mg/kg/day were submitted to two pharmacokinetic studies. The first was carried out during treatment by AZT only (test A) and the second after Itraconazole (2 x 100 mg/day) was added to AZT for at least 2 weeks (test B). Pharmacokinetic profiles were estimated by blood sampling at 0, 30, 60, 120, 240 minutes after the oral intake of 200 mg AZT. AZT serum concentrations were determined by a radioimmunoassay method using a iodine-125 tracer.
Results. AZT was not detectable in the sera prior to the tests. AZT peak serum levels were observed 30 minutes after the oral intake respectively in 5/7 and 7/7 patients during tests A and B. Mean maximal values (2466 ± 437 vs 2107 ± 257 ng/ml, NS) were comparable in the two profiles and were in the range of those previously reported. However, two patients presented better profiles of AZT concentrations during Itraconazole treatment.
Conclusions. These results confirm that AZT is rapidly absorbed from the gastrointestinal tract. Itraconazole seems to have no deleterious effect on the pharmacokinetics of AZT. The higher concentration observed in two patients during Itraconazole treatment could be the consequence of the improvement of the digestive candidosis and consequently a better resorption of the drug.

M.B.P.341 MOLECULAR INTERACTION OF RECOMBINANT β INTERFERON AND ZIDOVUDINE (AZT): ALTERATIONS OF AZT PHARMACOKINETICS IN HIV-INFECTED PATIENTS.

Nokta, Mostafa*; Loh, J.P.**; Douidar, S.M.***; Snodgrass, W.R.***; Ahmed, E.A.** and Pollard, R.B.*.
*Department of Internal Medicine, **Pathology and ***Pediatrics, The University of Texas Medical Branch, Galveston, Texas, U.S.A.

Zidovudine, the drug of choice for patients with AIDS, is known to be metabolized by mammalian systems to a variety of metabolites including 5'-azido-3'deoxy-5-O-glucuronide (GAZT). Interferons are known to alter the microsomal enzyme system responsible for metabolism of some drugs. The aim of this study was to investigate the effect of combination therapy of recombinant interferon-β (rIFN-β) and AZT on the pharmacokinetics and rates of metabolism of AZT in HIV-infected patients. AZT was given orally (200 mg every 4 hours) for 8 weeks prior to initiation of rIFN-β therapy ($90x10^6$ U/day, subcutaneously). Serum samples were obtained prior to and at days 3 and 15 following initiation of rIFN-β therapy. Serum was analyzed by high performance liquid chromatography (HPLC) for both AZT and GAZT. The serum data were analyzed by computer assisted pharmacokinetics program which calculates rates of AZT metabolism. The half life for AZT was increased 2 to 3 folds by day 15. The rate of metabolism of AZT was diminished from 1.18 hr^{-1} prior to rIFN-β therapy, to 0.4 hr^{-1} and 0.08 hr^{-1} at days 3 and 15 respectively. Volume of distribution of AZT was 2.7 L/Kg at day 0 and increased significantly to 7 and 5.8 L/Kg on days 3 and 15 respectively. Other kinetic parameters were also determined. In conclusion, this study indicates that rIFN-β inhibits the rate of AZT metabolism in AIDS patients.

M.B.P.342 INTRAVENOUS AND ORAL PHARMACOKINETICS OF ZIDOVUDINE IN HEMOPHILIA PATIENTS WITH HUMAN IMMUNODEFICIENCY VIRUS INFECTION.

Morse, Gene; Olson J., Portmore A., Taylor C., Plank C. and Reichman R.
University of Rochester AIDS Clinical Trials Group, Rochester, N.Y. USA.

Objective - To compare intravenous (iv) and oral (po) zidovudine (ZDV) kinetics in HIV-infected hemophilia patients during chronic dosing.
Methods - Nine patients received ZDV (300 mg po q4h while awake) for 12 weeks; iv and po kinetic studies were performed every 6 weeks. ZDV and ZDV-glucuronide (GZDV) were measured in plasma by HPLC.

Results - Week	1	6	12
ZDV-iv-2h(mcg/ml)	1.2 ± 0.4	1.2 ± 0.3	0.7 ± 0.3
ZDV iv-4h	0.2 ± 0.1	0.2 ± 0.1	0.3 ± 0.1
ZDV oral-2h	0.5 ± 0.4	0.4 ± 0.2	0.4 ± 0.1
ZDV oral-4h	0.1 ± 0.05	0.1 ± 0.04	0.1 ± 0.08
GZDV/ZDV-2h iv	2.6 ± 0.8	2.6 ± 0.8	2.5 ± 1.3
GZDV/ZDV-4h iv	2.7 ± 0.9	3.0 ± 1.9	2.7 ± 1.6
GZDV/ZDV-2h oral	4.6 ± 2.4	4.9 ± 2.2	4.4 ± 2.7
GZDV/ZDV-4h oral	3.8 ± 1.9	3.4 ± 2.0	2.7 ± 1.2

The iv ZDV half-life at 1, 6, and 12 weeks was 1.9 ± 1 h, 3.4 ± 3 h and 2.1 ± 1 h, while after oral ZDV it was 3.1 ± 3 h, 4.2 ± 2 h, and 3.4 ± 2 h.
Conclusion - Although the mean ZDV levels were similar, a high degree of intrapatient variation was noted. The lower concentrations after oral ZDV were most likely due to "first-pass" metabolism, as indicated by the GZDV to ZDV ratio. These data indicate that chronic therapy with a standardized ZDV dosage regimen may result in a variable plasma level profile.

M.B.P.343 PHARMACOKINETICS OF ZIDOVUDINE AND P24 Ag TIME-COURSE IN 48 ARC PATIENTS UNDER STEADY-STATE CONDITIONS.

DIQUET B., SIMON F., GRY-LAVOLLEE L., BRUN-VEZINET F., COLIN J-N., VIGIE GROUPE and al.
1 : Laboratoire Pharmacocinétique, Département de Pharmacologie Clinique, Hôpital de la Salpêtrière, 75013 PARIS - FRANCE.
2 : Laboratoire de Virologie, Hôpital Bichat Claude Bernard, 75018 PARIS -FRANCE.
3 : Laboratoires WELLCOME S.A., PARIS - FRANCE.
4 : V.I.H. Groupe INSERM d'essais thérapeutiques. Unité INSERM 292, Hôpital Bicêtre, 94275 LE KREMLIN-BICETRE - FRANCE.

Aims of the trial : 1) To assess the pharmacokinetics (PK) of zidovudine in patients on a chronic regimen. 2) To estimate the plasma time-course of the P24 antigen both after the first dose and under a chronic treatment. 3) To find a correlation between PK and antigenemia over a four week survey. 48 ARC patients (IVa CDC), 39 M 9F with positive P24 antigen entered an open randomized multicenter trial between 12-87 and 12-88. They were allocated to one of the 6 following zidovudine oral dose : 200, 300, 400, 600 every 8 hours, 300 mg every 6 hours, 600 mg every 12 hours.The protocol has been approved by local ethical comittee and the patients gave written informed consent.

Method : On Day 0 and DAY 14 patients were sampled at time 0 - 0.2 - 0.33 - 0.66 - 1 - 1.5 - 2 - 2.5 - 3 - 4 - 6 - 8 - 24 h and every 72 hours from D0 to D30 or D40. Samples were assayed for Ag and zidovudine and metabolite by immunocapture test (Abbot) and HPLC respectively.

Results : Preliminary data suggest that zidovudine undergoes extensive first pass effect as indicated by high plasma level ofa metabolite with a very short Tmax, closed to that of the parent compound. No antigen release was observed at any time. It should be noted that when occuring, significant antigenemia decrease or negativation is a rapid and early feature (2d to 9th day). Pretreatment antigenemia level and dosing regimen seem to be relevant for the interpretation of P24 Ag changes.

Conclusion : PK data and Ag concentration data allowed to develop concentration-effect relationship model.

M.B.P.344 PHARMACOKINETICS OF ZIDOVUDINE (AZT) AND ITS GLUCURONIDE (G.AZT) IN HEALTHY SUBJECTS AND IN UREMIC PATIENTS ; INFLUENCE OF HEMODIALYSIS

Singlas Eric*, Pioger J.C.*, Taburet A.M.*, Colin J.N.*, Fillastre J.P.**
*Clinical Pharmacy, Paris and **Nephrology, Rouen - France.

Pharmacokinetics of zidovudine (azidothymidine - AZT) was investigated after oral administration (200 mg) in 25 HIV seronegative subjects : 14 patients with severe renal impairment (creatinine clearance 6 to 31 ml/min), 5 hemodialyzed anuric patients, and 6 healthy subjects.

Plasma and urine concentrations of AZT and its glucuronidated metabolite (G. AZT) were measured simultaneously by HPLC assay. In healthy subjects, G.AZT concentrations are higher than those of AZT ; AUC were 10.5 ± 0.9 and 1.4 ± 0.2 h.mg/l respectively. Formation of G.AZT rate-limits its elimination : G. AZT half-life parallels that of AZT which is around 1 hour. In uremic patients AZT concentrations are moderately increased (AUC = 3.1 ± 0.3 h.mg/l), whereas half-life and MRT remains unchanged, despite the decreased renal clearance (16 ± 2 vs 220 ± 58 ml/min) and decreased urinary excretion (1.6 ± 0.3 vs 8.1 ± 1.0 % of the dose). In contrast G.AZT concentrations are markedly increased (AUC = 178.5 ± 39.2 h.mg/l). As a consequence of the decreased renal clearance (27 ± 3 vs 331 ± 42 ml/min), elimination is the rate limiting step and half-life is increased (8 ± 2 vs 0.9 ± 0.1 h). Contribution of a 4-hour hemodialysis session to AZT elimination appears negligible whereas elimination of G.AZT is enhanced. On the sole basis of AZT pharmacokinetic data no particular dosage adjustment appears necessary in patients with severe renal impairment. However with usual dosage regimen high levels of G.AZT should be anticipated and clinical consequences of such an accumulation remain to be established.

M.B.P.345 COMPARISON OF RADIOIMMUNOASSAY (RIA) AND HIGH PERFORMANCE LIQUID CHROMATOGRAPHY (HPLC) METHODS FOR SERUM ZIDOVUDINE (AZT) LEVEL MEASUREMENTS

Batra, Krishan; DeSouza, M.; Stephy, E.; Flynn, N.; Tonjes, T.
University of California, Davis, Medical Center, Sacramento, California, U.S.A.

Objective. The objective of this study was to compare the HPLC and RIA methods in measuring the AZT (Zidovudine) level after oral administration.

Method. 39 serum samples were drawn from 10 patients at zero, one and two hours post oral administration of Zidovudine. The serum concentration of Zidovudine was measured using both the HPLC method (ammonium phosphate buffer/acetonitrile mobile phase; wavelength 266 nm; 160 mm spherisorb ODS-2 5 microns column) on a Perkin Elmer LC-75 system, and a commercially available RIA kit. The RIA kit was provided by INCSTAR Corporation (Stillwater, MN). Controls were included in both methods. The results of the two methods were statistically compared using linear regression analysis.

Results. The results of the two methods did not correlate statistically (correlation coefficient=0.79). The zero, one and two hours post administration of Zidovudine serum levels were also compared. The correlation coefficient were 0.20, 0.75, and 0.68 respectively.

Conclusion. The results obtained by the RIA method did not correlate well with the HPLC method. The variation was not consistent. The RIA method values were consistently higher for the one hour and two hours post ingestion levels.

Thérapie et évaluation clinique : marqueurs de l'évolution en cours de thérapie
Therapy and Clinical Evaluation: Markers of Evolution During Therapy

M.B.P.346 THE ENUMERATION OF PERIPHERAL BLOOD HIV-ANTIBODY SECRETING CELLS AS A MONITOR OF THE ACTIVITY OF ANTIVIRAL DRUGS

André Nahmias, F. Lee, S. Nesheim, S. Lowery, A. Smith, S. Thompson
Depts. of Pediatrics and Medicine, Emory University, Atlanta, GA., U.S.A.

Objective. To determine rapidly the in vivo effectiveness of an antiviral drug, particularly in the absence of antigenemia or significant immunological or clinical abnormalities.

Methods. We have used the enzyme-linked immunospot (ELISPOT) methodology successfully to detect and enumerate circulating antibody secreting cells (ASC) specific to an HIV gp41 recombinant protein in children and adults infected with HIV. The population in the current study comprises adults with ARC or AIDS who were untreated or had received AZT for a minimum of 3 weeks.

Results.

	UNTREATED		TREATED WITH AZT	
	No. Tested	No. HIV-ASC Positive*	No. Tested	No. HIV-ASC Positive*
Patients with ARC	10	8	6	0
Patients with AIDS	6	4	7	1
Patients with ARC/AIDS	16	12(75%)**	13	1 (8%)**

*≥ 8 ASC to HIV per million peripheral blood mononuclear cells ** p<0.02

Discussion. The observed results could have been due to the suppressive effect of AZT on: (1) the ASC detection system in vitro; (2) the ability of the host to synthesize immunoglobulin in vivo; (3) the replication in vivo of HIV with concomitant reduction in the production of viral antigens required to boost the host's immune system for the persistence of circulating HIV ASC. The first two hypotheses have been excluded by experiments which demonstrated that AZT, up to 100 µM, had no effect on the detection system, and that subjects on AZT treatment showed no decreased numbers of total immunoglobulin secreting cells in the peripheral blood. We conclude then that the HIV ELISPOT detects an in vivo antiviral effect and that this method should prove useful in evaluating new antivirals in humans or experimental animals.

M.B.P.347 EVALUATION DES LYMPHOCYTES T ACTIVES ET DES SOUS-POPULATIONS NATURAL KILLER AU COURS DU TRAITEMENT PAR LA ZIDOVUDINE DE PATIENTS PRESENTANT UN ARC.

Levacher ,Maryse ; Dournon ,E. ; Tallet ,S. ; Rouveix ,B. ; Pocidalo J.J.; et le Comité AZT de l'Hôpital Claude Bernard. INSERM U.13, 10, Avenue de la Porte d'Aubervilliers 75944 Paris, France.

Objectif : Déterminer les effets de la Zidovudine (AZT) sur les lymphocytes T activés (HLA-Dr) et les cellules Natural-Killer (Leu2+ 7+) chez des patients présentant un ARC (AIDS-related-complex).

Méthode : Parmi les 80 patients présentant un ARC et recevant de l'AZT, 200 mg toutes les 4 heures par voie orale (E. Dournon et col. Lancet, 1988, ii : 1297-1302), 35 sujets pris au hasard ont fait l'objet de phénotypages lymphocytaires plus extensifs. Les lymphocytes sanguins ont été analysés sur cytométre en flux (FACScan Becton-Dickinson) après double marquage en immunofluorescence. Les combinaisons d'anticorps monoclonaux utilisées sont : Leu3 (CD4) avec Leu2 (CD8), mais aussi Leu2 avec Leu 7 et Leu4 (CD3) avec HLA-Dr (class II MHC). Les mesures ont été effectuées avant le début du traitement puis tous les mois durant une étude de 9 mois.

Résultats : Les taux de lymphocytes sanguins ne présentent que des fluctuations de faible amplitude. De même, les % de lymphocytes exprimant le marqueur membranaire CD3 (lymphocytes T) ne varient pas significativement. On n'observe pas non plus de modifications intéressantes des % de cellules Leu2+ (CD8) et Leu 2+ 7+ (Nature Killer). Par contre la fraction des lymphocytes T qui expriment le marqueur d'activation (Leu4+ HLA-Dr+) diminue de manière progressive et régulière jusqu'au 6è mois (Jo = 37%±2, 3è mois : 33%±2, 6è mois : 23%±2) pour augmenter ensuite (9è mois : 31% ±3). Enfin on retrouve la faible augmentation initiale des CD4.

Conclusion : Sur ce groupe de patients (ARC) le traitement par l'AZT entraine une diminution significative et importante deslymphocytes T activés qui correspond à la période d'amélioration clinique décrite.

M.B.P.348 Relevance of antigenemia in AIDS patients treated with AZT.

Bozza,Marie Christine*; Bourman,E**; Matheron,S*; Rozenbaum,W*; Gaudebout,C***; Brun-Vezinet,F* and the AZT comity Claude Bernard Hospital Group.
*Claude Bernard Hospital, Paris France. **Inserm U13, Paris, France.*** Raymond Poincaré Hospital, Garches, France.

In the HIV infected patients the quantitative measurement of antigenemia (Ag) was considered to provide an index of the antiviral effect of treatment. We evaluated the signifance of Ag in 56 AIDS patients (Pts) treated with AZT and belonging to the Claude Bernard Hospital AZT study cohort. All the Pts had had the first opportunistic infection (O.I) within the 8 weeks preceeding treatment and were followed up for a mean of 55 weeks (W.)
Antigenemia was assayed by Abbott antigen HIV EIA. The limit of sensitivity was 40 U/ml. T lymphocytes phenotyping was done by direct immunofluorescence with flow cytometry and monoclonal antibodies (Beckton-Dickinson).
Before treatment 35 Pts (46%) were Ag positif (+).We evaluated the predictive value of antigenemia at day 0 according to the clinical course of the Pts. We divided the Pts in 3 groups: Group I (n=18): Death; Group II (n=21): development of a new opportunistic infection (OI), Group III (n=17): No evolution of the disease.
The mortality rate (group I) did not differ in Ag(+) (n=12/35) Pts and in Ag(-)(6/21) Pts. The mean survival time was not different in Ag(+): 61 W and Ag(-): 66 W Pts. The occurence of OI (group II) was the same in Ag(+)(n=15/35) and Ag(-)(n=6/21) Pts. In the Ag(+) patients the mean Ag level at day 0 did not differ significantly in the 3 groups: Group I: 610 U/ml, Group II: 300 U/ml, Group III: 240 U/ml.
At day 0 the mean and median count of CD4 cells for the 3 groups was no different in Ag(+) Pts (66/mm³-median 48) and Ag(-) Pts (46/mm³-median 33).
At month 1, antigenemia decreased (≥ 2 fold the base value) or became negative in 51% of Ag(+) Pts. The same Ag course was observed in the 3 groups of patients.
Conclusion: Whatever Ag at day 0, we observed no difference in the clinical course of these 56 AIDS patients treated with AZT. Decrease of Ag at month 1 was not associated with any particular clinical evolution.In this group of AIDS patients, Ag had no predictive value.

M.B.P.349 CLINICAL AND LABORATORY EFFECTS OF AZT IN HIV POSITIVE MEN COMPARED TO A CONCURRENT CONTROL GROUP

M. Fanning, K. Johnson, J. Osachoff, J. Montaner, R. Coates, J. Ruedy, et al, University of Toronto, Toronto, ON; University of British Columbia, Vancouver, BC; McGill University, Montreal, QC, Canada.

Objective: To establish the efficacy of AZT during an open trial using a concurrent control group for comparison.
Methods: 20 patients from the Toronto site of the Canadian Multicentre AZT Dose Range Finding Study were matched with 20 controls from the University of Toronto Epidemiology Study using the criteria of platelet count, hemoglobin and T4 cell count. Laboratory and clinical parameters were monitored for 84 weeks. All patients were HIV positive but none had AIDS.
Results: Development of AIDS was greater in the control group (3/20 at week 72 and 6/20 at week 84) than in the AZT treated group (0/20 at week 72 and 2/20 at week 84). The small number of patients studied has limited the statistical power of this observation (p=.1138). No differences were seen over time between the groups for laboratory findings except absolute lymphocyte count, which declined from a mean of 2063 pre-AZT to 1512 at week 72 in the treatment group, compared to the control group whose relative counts were 2181 and 1936 (p<.05). T4/T8 ratios showed a (non-significant) downward trend in the control group compared to the treatment group.
Conclusion: AZT did not affect laboratory parameters (apart from lymphocyte count) to any greater degree than did the effect of untreated HIV infection. There may have been a slight protective effect of AZT on the T4/T8 ratio. AZT may prove to be effective in slowing the rate of conversion to AIDS, although further study needs to be done in this regard. The validity of concurrent control group comparison requires further evaluation.

M.B.P.350 CHEZ LE PATIENT, UNE FRACTION SEULEMENT DE L'INFECTION RETROVIRALE PARAIT SENSIBLE A L'AZT.

Mathez, Dominique*; Leibowitch, J.*; Cesari, D.*; Bélilovsky, C.*/**; Gorin, I.**; Deleuze, J.** et Paul, D.***
*Hopital Raymond-Poincaré/Université René-Descartes, Garches/Paris-ouest, France; **Hopital Tarnier, Paris, France; ***Abbott Laboratories, North Chicago, Etats-Unis

Objectifs: comparer chez un patient (CDC IV) sous AZT per os les niveaux successifs de rétrovirus exprimés in vivo dans les cellules mononucléées du sang (CMN).
Méthodes: les CMN (ficoll) séquentielles d'un meme patient sont décongelées simultanément, irradiées (60000 rads), et co-cultivées avec PHA-blastes normaux. Les vitesses moyennes de positivation des cultures (= score' en % du maximum, cf abstract connexe) donne une valeur de l'infection productive in vivo. Dosage de l'antigénemie p24/25* (S-p24, positif si DO Signal/Seuil >1).
Résultats: Score-vitesses' d'expression HIV par CMN irradiées et S-p24*

Patients	A	B	C	D	E	F	G	H	I	J
Avant AZT	93*/1.80	80/2.1	87/1.6	84/0.5	70/2.1	77/2.7	76/0.5	64/1.6	28/1.3	19/1.0
Minimum sous AZT	51*/1.10	21/2.3	00/1.0	25/0.5	15/3.0	05/0.7	10/0.5	00/1.3	02/1.4	00/1.5
(jrs..)	(40)	(45)	(14)	(8)	(21)	(45)	(60)	(38)	(160)	(30)
Maximum sous AZT	77*/0.90	61/0.7	71/1.5	40/0.5	49/0.6	60/0.6	50/0.6	16/1.0	31/1.3	17/0.7
(jrs..)	(80)	(300)	(25)	(25)	(340)	(225)	(300)	(175)	(395)	(300)

Conclusions: L'infection rétro-virale active persiste sous AZT après réduction significative mais transitoire. Le processus infectieux AZT-résistant semble peu générateur de S-p24. Le système d'évaluation à partir des CMN irradiées pourrait être un substitut biologique aux points de mesures cliniques dans les essais thérapeutiques.

M.B.P.351 PERSISTING OF HIV-VIREMIA IN p24 ANTIGEN NEGATIVE SUBJECTS RECEIVING ZIDOVUDINE.

Cinque,P.*; Lazzarin,A.*; Varnier,O.**; Bini,T.*; Terzi,R.*.
*Inf. Dis. Clinic, Milano, Italy. **Inst. of Microbiology, Genova, Italy.

Objective. To determine the relationship between serum p24 antigen, HIV viremia and HIV infection complications in subjects receiving Zidovudine (ZDV).
Methods. We studied 15 patients with AIDS and ARC: 13 of them received ZDV (500 mg x 4/die for 4 week, followed by 250 mg x 4 for 20 months; dosage was reduced in 4 patients; 2 received placebo. Lymphocytes were cultured monthly to assay the reverse transcriptase (RT) activity. HIV p24 in serum was detected monthly with a capture assay (ELISA DuPont).

Results.	ZDV : RTpos	p24pos	placebo: RTpos	p24pos
-before treatment	13 (100%)	7 (54%)	2 (100%)	2 (100%)
- 4 weeks	7 (54%)	1 (8%)	2 (100%)	2 (100%)
- 8 weeks	3 (23%)	0 (0%)	2 (100%)	2 (100%)

The 3 RT positive patients maintained the positivity in the following months: all died (11,20,21 months). In 7 other patients HIV was isolated in successive detections: 4 developed opportunistic infections, 1 died (16 months). In 3 patients HIV was never isolated: only 1 developed a peripheral neuropathy.
Conclusion. Morbility is associated with persistent viremia. In some subjects the used dosage of ZDV is sufficient to reduce viral replication with lack of detectable antigen in serum, but not to have a complete inhibition. This could be correlated with a low dosage or with a high virus replication.

M.B.P.352 DISEASE PROGRESSION DESPITE ANTIGEN DECLINE DURING ZIDOVUDINE TREATMENT OF ASYMPTOMATIC HIV-INFECTED SUBJECTS: NEED FOR PLACEBO-CONTROLLED TRIALS

Lange, Joep*; Mulder, J.**; De Wolf, F.*; Coutinho, R.** and Goudsmit J.*
*Academic Medical Centre, University of Amsterdam, Amsterdam, the Netherlands.
**Municipal Health Service, Amsterdam, the Netherlands.

Objective. To study the feasibility, antiviral and immunological effects of long-term simplified-dosage zidovudine (AZT) treatment of asymptomatic HIV-infected subjects.
Methods. 18 asymptomatic men with persistent HIV-1 p24 antigenemia were treated with zidovudine 250-500 mg (± acyclovir 800 mg) 6-hourly for 4-12 weeks, and subsequently with zidovudine 500 mg (± acyclovir 1600 mg) for 60 weeks. Six additional HIV antigenemic men were treated directly with zidovudine 500 mg 12-hourly for 48 weeks.
Results. Over the treatment period serum HIV-1 p24 (HIV-Ag) levels declined in 23/24 men. Mean serum HIV-Ag levels in different treatment-groups declined 65-80%. Acyclovir addition made no obvious difference. Median CD4+ cell counts at the end of the study period were at pretreatment level. In 2 men Pneumocystis carinii pneumonia was diagnosed after 60, respectively 80 weeks. Adverse reactions to the study drugs were infrequent and mild. Anemia caused symptoms in 3 men; serious leucopenia or neutropenia was not observed.
Conclusion. Both 250 mg 6-hourly and 500 mg 12-hourly are effective zidovudine starting-doses; prolonged suppression of viral replication is feasible with a 12-hourly maintenance dose. However, even with early zidovudine treatment and considerable suppression of HIV-Ag production disease progression can still occur. Tolerance of treatment warrents placebo-controlled trials.

M.B.P.353 FOLLOW-UP OF IN- VITRO IMMUNOLOGIC PARAMETERS AND INTERFERON PRODUCTION DURING LONG- TERM ZIDOVUDINE TREATMENT IN HIV- POSITIVE PATIENTS.

Biglino,Alberto; Pugliese,A., Forno,B., Pollono,A., Busso,M., Sciandra,M. and Gioannini P.
Institute of Infectious Diseases, University of Torino, Torino, Italy

Objective: to assess the influence of zidovudine (ZVD) treatment on functional parameters of cell-mediated immune response in vitro (proliferative response to T- and B-cell mitogens, production of gamma-interferon and Interleukin 2) and on spontaneous and virus-induced alpha Interferon (Ifn) production.
Methods: Peripheral blood mononuclear cells from 15 consecutive HIV+ patients in stage IV (A, B or C2), were incubated with optimal concentrations of PHA, CON-A and PWM, and with or without Newcastle disease virus strain F, before starting ZVD, and after 2 and 6 months of treatment (3.5 mg/kg/4hrs). Proliferative responses were assessed by 3H-Tdr incorporation and expressed as D-CPM, while biological assays were employed to assess Ifn and IL-2 levels. Results were evaluated with repeated - measures ANOVA, and with Friedman test for not - normally distributed values.
Results: Clinical stage of patients remained unchanged during the study. Mean proliferative response to PHA and CON-A did not show any significant variation, while mean response to PWM increased from 9860 to 17046 CPM after 2 months, and dropped to 10400 by the end of the study (P=0.048). A moderate (though not significant) decrease in gamma- and alpha-Ifn production was observed. By contrast, spontaneous alpha-Ifn release dropped significantly at 2 months, and remained at very low levels at 6 months (P=0.0022), while IL-2 production rose particularly after 2 months (rank 11th to 19th; P=0.0261).
Conclusions: Our preliminary report indicates that long-term ZVD treatment is devoid of any adverse effect both on proliferative response to mitogens and on alpha- and gamma-Ifn yield in vitro. A significant increase in response to PWM and in IL-2 production was observed, suggesting a functional recovery of B- and T-cell, possibly related to impairment of HIV replication. This hypothesis seems to be confirmed by a significant depression of spontaneously released alpha-Ifn (a possible marker of non-T cell infection by HIV, data in press)

M.B.P.354 AZT TREATMENT INDUCES A DECREASE OF SOLUBLE INTERLEUKIN 2 RECEPTOR (sIL-2R) BUT NOT OF SOLUBLE CD8 ANTIGEN (sCD8) SERUM LEVELS IN HIV INFECTED PATIENTS.

Galli,Massimo; Balotta,C.: Ridolfo,A.L.; Cocchi,F.; Uberti-Foppa,C. and Moroni,M. Clinic of Infectious Diseases, University of Milan, Italy.

Objective. To investigate whether sIL-2R and sCD8 levels differ in patients with CD4 counts higher or lower than 400 cells/mm3 and whether AZT influences the serum levels of sIL-2R and sCD8 Ag.
Methods. sIL-2R and sCD8 have been measured in 52 HIV infected patients (12 AIDS) and 12 healthy controls (HC) using an ELISA method (T Cell Science). In 10 AZT treated patients the tests were repeated on the 30th and 90th day of therapy and p24 Ag (T Cell Science) was determined on a parallel.
Results. All patients had markedly elevated sIL-2R and sCD8 levels respectively (2202±1107 U/ml in patients vs 332±126 in HC, p 0.0001; 992±376 U/ml vs 346 ±78 in HC, p 0.0001). No significant differences were found either between subjects with CD4 cell counts higher or lower than 400 c/mm3 or between patients with or without AIDS. A significant reduction of sIL-2R serum concentration was observed during AZT treatment in all patients (mean:T0 1811 U/ml, T30th 1215 U/ml, T90th 1193 U/ml, p 0.005) but 1 presenting persistent antigenaemia.
Conclusions. AZT seems to reduce the release of sIL-2R, possibility as a consequence of a reduced destruction of T/helper; no influence can be demonstred on sCD8 level. Our results suggest that sIL-2R serum level determination could be a usefull tool in monitoring AZT therapy effects.

M.B.P.356 PREDICTIVE VALUE OF CD8 CELL COUNT IN MORBIDITY AND MORTALITY AMONG AIDS AND ARC PATIENTS (P) TREATED WITH ZIDOVUDINE (AZT)

Gerard, M.; Sommereijns, B.; De Wit, Stéphane; Clumeck, N.
Division of Infectious Diseases, St Pierre University Hospital, Brussels, Belgium.

We prospectively studied a population of 45 AIDS P and 81 ARC P under AZT treatment (T) for a mean period of 34 weeks to assess their immunological and clinical evolution. CD4, CD8, blood cell count and physical examination were obtained monthly. Baseline CD4 cell count lower than 100/mm3 was associated with a higher incidence of opportunistic infections (OI) (37% vs 7%-p=0.0007) and a higher case fatality rate (25.5% vs 2.4%-p=0.0002). The same correlation was found for low CD8 cell count. There were 10 ARC P and 17 AIDS P with baseline CD8 cell count below 400/mm3 and 71 ARC P and 28 AIDS P with baseline CD8 cell count over 400/mm3. OI occured during AZT T among 40% of ARC P with CD8 value below 400/mm3 and 8% of ARC P with CD8 value over 400/mm3 (p=0.02). There was no influence of CD8 value on occurence of OI in AIDS P. Low CD8 cell value in both AIDS and ARC P was also correlated with higher mortality: 40.7% of P died if baseline CD8 cell count was lower than 400/mm3, 3% of P if baseline CD8 cell count was higher than 400/mm3 (p=0). Positive predictive value of occurence of OI and death among P with CD4 value lower than 100/mm3 were respectively 45.8% (57% for ARC P, 41.2% for AIDS P) and 45.8% (42% for ARC P, 47% for AIDS P) if baseline CD8 cell count was lower than 400/mm3 and respectively 18.2% (23% for ARC P, 15.4% for AIDS P) and 4.5% (0% for ARC P, 7.7% for AIDS P) if baseline CD8 value was over 400/mm3.
In HIV P treated with AZT, low baseline CD8 cell count has a predictive value for developing AIDS in ARC P and CD8 cell count enhances the predictive value of CD4 cell count for OI development and occurence of death.

M.B.P.358 ERYTHROCYTE ADENOSINE DEAMINASE (ADA) EXPRESSION IN AZT-TREATED AIDS PATIENTS

Casoli,Claudio;Magnani,G.*;Barbuti,S.;Barchi,E.*;Bertazzoni,U.**;
Fiaccadori,F.*,Starcich,B.
Istituto Patologia Medica,*Cattedra di Malattie Infettive,Universita' di Parma
**Istituto di Genetica Biochimica ed Evoluzionistica del CNR,Pavia,Italy.

Objective To assess the erythrocyte ADA expression in AZT treated patients.
Methods Measurement of ADA activity and enzymatic determinations of dATP and ATP in erythrocyte extracts of 9 AZT-treated patients (5 ARC,4 AIDS) with sexually transmitted HIV-1 infection. One unit of ADA activity is 1 nmol of inosine formed in 1 min. ATP and dATP concentrations are expressed in nmol/ 10^{9} cells.
Results Before AZT therapy. ADA activities were significantly higher (p<.001) in ARC and AIDS patients (39.5 U ±7.2) compared to controls (30 cases;9.5 U±1.8).dATP concentrations were in the normal range (< 2),while ATP values were low (mean 102 v.s. 148 of the controls).
During AZT therapy. A progressive increase of ADA (100 ÷ 150) was detected during the first 3 months of the treatment.Subsequently constantly high activities were monthly observed.After 3 mo the ATP concentrations (mean 58.7) were by approximately 50% reduced,whereas dATP concentration was low.
Conclusion We have observed increased ADA activity and decreased ATP concentration in the erythrocytes of 9 ARC/AIDS patients.Such phenomenon was enhanced by AZT therapy.Since ADA and adenosine kinase compete for a common substrate,the greatly increased activity of the former may interfere with nucleotide salvage by the latter.From which macrocitic anemia may ensue.

M.B.P.355 AZT THERAPY IS ASSOCIATED WITH AN INCREASED CAPACITY OF PHA-STIMULATED CELLS TO EXPRESS IL-2 RECEPTORS (IL-2R).

Winkelstein, Alan*, McMahon, D.*, Hawk, H.*, Armstrong J.A., Pazin, G.J., Ho, M. and Pittsburgh AIDS Clinical Trial Unit
*Department of Medicine, School of Medicine, and Division of Microbiology, Graduate School of Public Health, University of Pittsburgh Pittburgh, PA, U.S.A.

Objective: To determine whether AZT therapy in HIV+ patients can improve in vitro T lymphocyte function.
Methods: 34 AIDS patients enrolled in the 002 ATEU protocol for AZT treatment were sequentially evaluated at intervals up to one year. PHA-stimulated mononuclear cells were incubated for 24 hours; the cells were cytoflourographically analyzed for expression of IL-2R by reactivity with CD25 monoclonal antibody.
Results: At time of entry, IL-2R expression were markedly depressed in HIV+ subjects. The mean value 5.4± 0.9% compared to 63.3 ± 2.6% in heterosexual controls. In the treated patients, there was a progressive increase in the capacity of cells to express IL-2R. Data was calculated by two methods. The average IL-2R, using the last observation, had increased to 13.4 ± 2.4% (p<0.01 compared to baseline). When all values during the treatment period were considered, the mean was 17.0 ± 2.6%. Further analysis suggested that in the HIV+ treated patients, the responsive cells were primarily of the CD8 phenotype whereas, in controls, they were mostly CD4+. During the year of treatment, there was no increase in either PHA of T cell colony responses.
Conclusions: These studies suggest that AZT therapy is associated with a sustained improvement in one functional parameter of T cell reactivity; their capacity to be activated by PHA, as indicated by expression of IL-2R.

M.B.P.357 QUANTITATIVE DOSAGE OF CORE ANTIBODIES IS A BETTER PRONOSTIC MARKER THAN HIV ANTIGEN ASSAY.

Liesnard,Corinne;Przedborski,S.;Farber,C.-M.
Hopital Erasme, Université Libre de Bruxelles, Brussels, Belgium.

Methods : During a follow-up period of 0.5 to 39 months (mean : 13.9 months) sera of 30 European and 16 African HIV infected patients (pts) at all stages of the disease (i.e. : asymptomatic, PGL, ARC, AIDS) were retrospectively investigated for the presence of HIV antigen (Ag), core antibodies (Ab) and envelope (env) Ab (Abbott Diagnostics-North Chicago-Il).
Results : In all pts, env Ab were detected in high titers without significant variations during the follow-up. HIV Ag was detected in the serum samples of 14 pts : 1 African with AIDS and 13 Europeans. At the beginning of the follow-up, 10% of the European pts were antigenemic and 20% at the end. Core Ab were detected during the follow-up period in all the Africans except in the pt with HIV Ag. The geometric mean (GM) of core Ab titers was 1/6738 in the asymptomatic pts and 1/113 in the AIDS pts. All European pts without HIV antigenemia had core Ab; 4 of them lost their Ab during the follow-up period. 9 out of 13 European HIV antigenemic pts had core Ab; 4 of them lost their Ab during the follow-up period. The GM of core Ab titers was 1/26 in the asymptomatic pts and 1/5.5 in the AIDS pts.
Conclusion : HIV Ag is rarely expressed in African pts; moreover, even in the late stage of the disease, HIV Ag is not detected in 37% of European pts and detection is intermittent. In contrast, the decline or the disappearance of core Ab is clearly related with evolution of the disease, in African like in European pts. Follow-up of quantitative dosage of core Ab seems to be of more value as a pronostic marker than the detection of HIV Ag.

M.B.P.359 EFFECT OF AZT CESSATION ON LEVELS OF ANTIBODIES PARTICIPANT IN ANTIBODY DEPENDENT CELL CYTOTOXICITY (ADCC) REACTIONS

Dascal,Andre ,Zeira,F.,Tsoukas,C. ,and Wainberg,M.A.
SMBD-Jewish General Hospital and Montreal General Hospital, McGill University, Montreal,Canada.

Objective. To assess the effect of AZT cessation on levels of ADCC-relevant antibodies in patient sera.
Method. A standard 6 hour ^{51}Cr release cytotoxicity assay was used to assess ADCC activity longitudinally over a 20 month period in 2 asymptomatic HIV-1 seropositive patients that had transiently stopped AZT therapy. In addition sera from a healthy control seronegative donor was used. Target cells were uninfected and HTLV-IIIB infected U-937 cells,dispersed into 96 well microtiter plates (5000 cells/ well). Serial 10-fold-dilutions of sera from each time point for each patient and the control were added to the targets to achieve final serum dilutions of 1:100 to 1:100,000. Effector lymphocytes obtained from a seronegative healthy donor were added to the wells at a effector:target ratio of 15:1.
Results. At dilutions 10^{-2} and 10^{-3} of patient sera, we noted ADCC activity in both patients. This activity was less marked at a 10^{-4} dilution and disappeared at 10^{-5}.Upon initiation of AZT therapy, ADCC activity diminished progressively in the patients until AZT was stopped. Sera obtained immediately following a 6 week wash out period showed a marked rise of ADCC activity to baseline levels.
Conclusion. These data on 2 patients suggest that ADCC antibody activity diminishes while patients are on AZT and that this activity rebounds following cessation of drug. These findings are being expended to provide further insight into the role of ADCC in pathogenesis and/or protection in HIV-associated disease.

M.B.P.360 Effect of azidothymidine (AZT) on neopterin, β2-microglobulin, soluble CD8, soluble interleukin-2 receptor, tumor necrosis factor and HIV P24 antigen levels in patients with AIDS-related complex and AIDS.

Mohan M. Reddy, Ph.D., George McKinley, M.D., Arthur Englard, M.D. and Michael H. Grieco, M.D. St. Luke's-Roosevelt Hospital Center, New York, New York 10019, USA.

Nine patients with AIDS-related complex and 11 AIDS patients with *Pneumocystis carinii* pneumonia were treated with AZT 1500 or 1200 mg/day and followed for up to 72 weeks. Subsequently, the dose was reduced to 600 mg/day in some patients. Circulating neopterin, β2-microglobulin (β2-M), soluble CD8 (SCD8), soluble interleukin-2 receptor (SIL-2R), tumor necrosis factor (TNF) and HIV P24 antigen levels were measured at 4 weeks before treatment, at baseline and following AZT therapy at 4-week intervals. The results (means±SEM) are shown below.

Weeks	Neopterin ng/ml	β2-M μg/l	SCD8 units/ml	SIL-2R units/ml	TNF pg/ml	P24 Antigen pg/ml
-4	10.8±0.8	5835±680	1288±149	1162±85	10.6±5.1	152±33
0	11.9±1.0	5435±550	1232±128	1045±90	10.0±3.1	163±40
+4	10.6±1.2	4358±340	1040±125	1054±106	19.6±7.9	124±82
+8	9.2±1.2	4328±491	1161±132	1004±105	16.7±9.9	61±17
+12	8.3±1.4	3587±212	944±97	928±102	17.8±5.1	54±16
+16	9.6±1.0	3900±236	999±83	980±106	8.6±3.9	55±10
+20	10.9±1.7	5028±700	1064±140	965±156	12.8±8.5	29±16

Neopterin, β2-M and SCD8 levels decreased after 12 weeks of AZT treatment. However, these values increased towards pretreatment values by 20 weeks of drug administration. In contrast, HIV P24 antigen levels decreased significantly after 12 weeks of treatment and remained low after 20 weeks of AZT treatment.

M.B.P.361 SEROLOGIC HIV Ag LEVELS AND AZT THERAPY IN DRUG ADDICTS

Cargnel, Antonietta; Meraviglia P.; Valsecchi L.; Gubertini G. Mezzenzana M.A.; Zanchetta N.*
2nd Dept. of Infectious Dis.;*Dept. of Hygiene; L.Sacco Hosp.; Milan; Italy.

Objective: To estimate HIV Ag modification in drug addict patients treated with Azidotimidine (1200 mg/die).
Methods: Fifty-four HIV Ab positive patients were studied and followed within a 3-12 months period (average 125 days): 9 AIDS (4 HIV Ag positive), 26 ARC (11 HIV Ag positive), 19 PGL (13 HIV Ag positive).
Results: Among the 28 HIV Ag positive patients, 8 (28.5%) became seronegative in an average period of 90 days (1 AIDS, 3 ARC, 4 PGL). Among the three ARC seronegative patients at the third month of therapy two seroconverted at the sixth and at the twelfth month respectively. Also two among the four PGL patients who were seronegative at the third month of therapy, were again positive at the sixth month but at antigenemic titles lower than before treatment. During the therapy, 3 ARC patients who were seronegative at time of recruitment (11.5%) became HIV Ag seropositive. At the same time one of these three patients was diagnosed as AIDS. There was the evolution to worse stages of the disease in four cases (7.4%): 3 ARC (5.5%) and 1 PGL (1.8%). Opportunistic infections were observed only in 2 AIDS patients during AZT treatment.
Conclusions: AZT treatment seems to lower seric HIV Ag levels and to reduce the evolution of the HIV correlated disease.

M.B.P.362 EFFECT OF ZIDOVUDINE ON HEPATITIS B VIRUS (HBV) REPLICATION IN PATIENTS WITH CHRONIC HIV AND HBV INFECTION.

An inhibitory effect of 3' Azido 3' Deoxythymidine Triphosphate on hepatitis B virus (HBV) DNA polymerase has been shown in vitro and in an animal model. Objective : to assess the effect of Zidovudine (AZT) on HBV replication, as reflected by serum HBV DNA, in patients with HIV-HBV coinfection. Patients and methods : fifteen patients, mean age 36 years (range 25-48) were studied : 13 were homosexual or bisexual, 2 were intravenous drug addicts. One patient had AIDS Related Complex (ARC), 2 had Persistent Generalized Lymphadenopathy (LPG) ; 12 had AIDS. All were chronic HBV carriers with replication (presence of HBeAg and HBV DNA in the serum). No patient had antibodies against Hepatitis Delta Virus. Twelve patients had elevated serum aminotransferase. All patients received AZT at full dose of 200 mg orally every 4 hours. The mean duration of treatment at full dose was 14 weeks (range 1-65) ; in 11 patients (73 %) AZT dosage was reduced by half because of leucopenia. Indeed AZT therapy was given for a mean total duration of 39 weeks (range 6-59). Serum HBV DNA was assessed every month during treatment.
Results : Serum HBV DNA remained positive in all patients, and did not change significantly in any patient at any time during treatment.
Conclusion : Our results show that AZT therapy has no inhibitory effect on HBV replication, as assessed by serum HBV DNA, in chronic HBV carriers with HIV infection.

M.B.P.363 EFFECT OF ZIDOVUDINE ON HIV RELATED ARTHRITIS

Goffi S., Vezzani F., Giudici M.G., Tuzza A.
Divisione Malattie Infettive, Arcispedale S. Maria Nuova, Reggio Emilia, Italy.

Objective: to investigate the effect of zidovudine on cure for migrating and relapsing arthritis in a subject with HIV infection.
Methods: a male 22 years old, irregularly drug user, was diagnosed as HIV-infected on April 1986, by enzyme linked immunosorbent assay and WB confirmatory test. The patient was well and showed no sign of immunodeficiency and so he was assigned to the II^{nd} group of CDC classification. Laboratory studies evidenced 2511/mm^3 lymphocytes (20% T helper; 43% T suppressor). The patient was well until August 1987, when he had a febrile acute athrosinovitis involving right knee. Synovial fluid analysis disclosed a sterile fluid with 12500 cells, mainly lymphocites (65%). Haematological studies showed 13740 WBC (62% N; 22% L; 13% M; 3%E); VPI 56, the body temperature was 38° C; No other possible cause of infection or secundary arthrosinovitis was revealed. X-Ray film of the knee showed no lesions. FANS were administered and the patient recovered and was discharged on the 9th day. After 1 month, the arthrosinovitis relapsed on the right knee with the same characteristics. Approximately four months after the first episode, another arthrosinovitis developed in the left knee. The same illness had 5 relapses in the following 7 months and the patient was always treated with FANS. 11 months after the first episode, HIV culture of synovial fluid was negative. We weren't able to demonstrate positivity for HIV-antigen on serum and articular fluid. We failed to demonstrate HLA B-27 also. In that time, laboratory studies evidenced total lymphocytes 2803 (26% T helper; 43% T suppressor). No clinical sign of worsening of immunodeficiency was desclosed. Zidovudine 1200 mg/die was administered and the arthrosinovitis didn't relapse over the succeeding 6 months. Conclusion: in spite of failure of the demonstration of HIV in the synovial fluid, it's very reasonable that HIV is directly involved in relapsing and migrating arthrosinovitis: that's demonstrated also by the efficacy therapy with zidovudine. However, further studies are necessary.

M.B.P.364 HIV-ASSOCIATED ALOPECIA IN A WOMAN AND REGROWTH OF HAIR AFTER ZIDOVUDIN-THERAPY (A CASE-REPORT)

Vernazza Pietro L., Galeazzi R.L.
Medizinische Klinik A, Kantonsspital, St. Gallen, Switzerland.

Hair loss is quite a common finding in ARC- and AIDS-patients. We describe a patient with diffuse alopecia and wasting-syndrome with reproducible regrowth after zidovudine-therapy.

A 26-year old white, HIV-positiv woman presented with atopic neurodermitis, recurrent fever and weight-loss and almost complete alopecia. Clinical and laboratory examinations showed no evidence of Lupus erythematodes, syphillis or an other illness, that could explain the alopecia.
After 4 months of therapy with zidovudin for her HIV-Infection, her hair showed a striking recovery and she stopped wearing her wig.

Then, zidovudin hat to be discontinued due to granulocytopenia. Two weeks later she developped a candida-esophagitis and was treated with ketoconazole for 10 days. From now on, she had no therapy at all except methadone.
After 3 months without any antiretroviral therapy, she presented again with an almost complete baldness. Zidovudin was readministred. One week later, we found growth of new and thin hair. Ten weeks after readministration of zidovudin at a dose of 200mg q6h we found marked growth of new and thick hair.
We conclude that HIV-associated alopecia may be reversible under zidovudin-therapy. Photographic documentation will be presented and possible pathophysiologic mechanism discussed.

M.B.P.365 DERMATOLOGICAL MANIFESTATIONS DURING ZIDOVUDINE TREATMENT

Fröschl,Monika; Stallmann,D.; Holzmann,H.; Landthaler,M.; Braun-Falco,O.
Dermatological department of Ludwig-Maximilians-University, Munich, FRG.

Objectives: To determine the course of dermatological symptoms during zidovudine treatment. Methods: Dermatological manifestations of 33 patients treated for 35.5 weeks (4 - 84 weeks) with zidovudine 6 x 200 mg or 4 x 250 mg orally were observed. Results: Regarding Kaposi's sarcoma, 6/12 patients showed a stabilisation or partial regression of their lesions. Oral hairy leukoplakia healed in 54.6 % of cases. In oral candidosis 6/10 had no relapse after antimycotic therapy at beginning of zidovudine treatment. Therapy-resistent psoriasis in 3 patients healed partially or completely 10 weeks after beginning of zidovudine treatment. Conclusions: Zidovudine treatment reduces relapses and leads to a better response to local therapy of dermatological manifestations.

M.B.P.366 TREATMENT OF ADVANCED AIDS RELATED KAPOSI'S SARCOMA (KS) EXPERIENCE WITH 112 PTS FROM ONE INSTITUTION.

Gill Parkash, Levine AM, Bernstein-Singer M, Espina B, Barick M. University of Southern California, Los Angeles, CA, USA.

Objective: To describe the treatment of AIDS related Kaposi's sarcoma (KS) in 112 patients from a single institution.
Methods: 112 Patients (Pts) who had advanced KS were accrued to three different treatment regimens, from 1985 to 1988. Pts received either Adriamycin (A) alone, combination of A, Bleomycin, and Vincristine (ABV) or BV. 21 pts were subsequently given recombinant alpha interferon 2A (Schering) as maintenance therapy at doses of either 5,10, or 15 million units SQ daily, at time of KS response.
Results: Pts had extensive KS with >60% having greater than 50 cutaneous lesions and 23% with symptomatic visceral involvement. Severe immune dysfunction was present with a history of opportunistic infection (OI) in 22% and CD4 lymphocyte <200/mm^3 in 90%. Response rates were: 88% with ABV (63 pts), 72% with BV (18 pts), and 48% with A (31 pts). Major toxicity was neutropenia <1000/mm^3 in 60% of pts receiving A containing regimens. Median survival was 9 months in all Rx groups. 20% of the pts receiving alpha INF 2A as maintenance therapy had further resolution of disease or prolonged freedom from progression without noticeable decline in p24 Ag levels.
Conclusion: 1) Advanced KS can be successfully treated with combination chemotherapy; 2) Survival is short, due to development of OI as well as KS progression; 3) factors predictive of short survival are weight loss and CD4 lymphocyte count <100/mm^3; 4) alpha INF 2A has limited but definite benefit as maintenance in some pts with advanced KS.

M.B.P.367 BONE MARROW CHANGES IN HIV-1 POSITIVE ASYMPTOMATIC PATIENTS ON ZIDOVUDINE

M. Fanning, K. Gelmon, J. Falutz, J. Montaner, C. Tsoukas, J. Ruedy, et al, Universities of Toronto, British Columbia, and McGill.

Objective: A Canadian Multicentre Dose Range Finding Study was initiated to determine the effect of escalating doses of zidovudine on the bone marrows of 72 HIV positive patients (CDC groups II, III, IVC$_2$).
Methods: Therapy consisted of 600 mg/day for 18 weeks, incrementally increased to 1200 mg/day at 27 weeks. Patients were clinically evaluated q 3 weeks and had bone marrow biopsies and aspirates at the start of therapy and at every dose change for a total of 5 studies per patient. 305 aspirates and 267 biopsies were obtained from 65 patients who completed the 42 week trial.
Results: Pretreatment marrows showed plasmacytosis in 10 patients (17%), lymphoid aggregates in 18 (20%) and abnormalities in iron stores in 37 (54%). 63 marrows were normoblastic; 66 had normal myelopoesis. After the initial dose of 600 mg/day, 3 marrows remained normoblastic, 33 were megaloblastic, 5 showed dyserythropoesis, and 27 showed both megaloblastosis and dyserythropoesis. With increasing dose and duration of therapy there was increasing dyserythropoesis. After a 6 week washout of drug, 18 of 60 marrows returned to normoblastic. One patient developed red cell aplasia at week 36. Marked changes were noted in the myeloid series with a left shift. Megakaryocytes varied unrelated to platelet counts.
Conclusion: The effects of zidovudine on the bone marrow occurred at a low dose of 600 mg/day. The lack of reversibility of the changes on the erythroid and myeloid series may suggest a stem cell defect. The large number of all types of iron abnormalities requires further study.

M.B.P.368 EVALUATION OF THE ASSOCIATION OF ZIDOVUDINE (Z) and VINBLASTINE (V) IN TREATMENT OF AIDS-RELATED KAPOSI'S SARCOMA (KS).

Gharakhanian Shahin, De Sahb R., Vaseghi M., Cardon B., Rozenbaum W. Infectious Disease Unit, Rothschild Hospital, Paris, France.

Objective. To evaluate tolerance of a treatment associating Z and V for patients with KS.
Methods. 22 male patients (pts), mean age 40.2 years (22-58), 6 of whom had had prior opportunistic infections, were followed-up for a mean 6 months (2-11) in an open study. Treatment with Z and V was initiated a mean 17±12 months (2-47) after diagnosis of KS. V was administered by weekly IV injection, mean dose 2.9 mg (2-6). Z was initiated at 600 mg/day. All pts received Trimethoprim-Sulfamethoxazole for prevention of pneumocystis. Evaluation was by monthly clinical examination and CBC, which were compared with pre-treatment values (M0) at M 1,2 and 3 (t-test).
Results. Compared to initial values, the Hb, WBC and PMN counts were significantly lower at M 2 & 3. WBC and PMN counts were significantly lower at M 6. Platelet counts were significantly higher at M 1,2 & 3 (table 1). PMN nadir was 500/mm³ and Hb nadir was 7.4g/l. V was interrupted at least once in 14 of 22 pts after 4.6±2.3 months, due to neutropenia. Z was reduced or interrupted in 11 pts. Of 16 pts followed-up for 6 months or more, 2 died (KS and toxoplasmosis) and 4 ended treatment (neutropenia). KS was stable in 12 pts, worse in 7 and improved in 2 (table2).

TABLE II

[illegible]	[illegible]	STABILIZATION	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]

[illegible]

Conclusion. The toxicity generated by the treatment of KS with an association of Z and V appears to be acceptable. A controlled study is necessary to assess the benefit on KS and immune function, of Z + V taken together or separately.

M.B.P.369 *RESULTS AFTER 18 MONTHS OF TREATMENT WITH ZIDOVUDINE.*

MªJosé Mellado, MJ.Cilleruelo, J.Villota, G.Barreiro, ML.Péres, PM.Fontelos. Instituto Carlos III. S.Pediatria. Madrid. SPAIN.

OBJECTIVES: We analyse the evolution of one child with AIDS who was the first case in Spain who received treatment with Zidovudine (ZDV).
MATERIAL AND METHODS: We study a female, 6 years old, who presents a Von Willebrand disease. On April 85, she got infected by HIV when she was transfunded with commercial VIII factor that later was confirmed to be contaminated by this virus. She's remited to our Centre in November 87 to be studied and she was includes in P$_2$CD$_2$D$_3$ class according to CDC classification for pediatric AIDS. On December 87 she began treatment with ZDV, 14 mg/K/d during 10 months and later this dosage was doubled.
RESULTS: Her clinical evolution depends on her lung disease, lymphocytic interstial pneumonia (LIP). She has suffered recurrent pneumonias by H. Influenzae, S. Penumonias and S. Aureus once a month. These processes have decreased in number, one every 3 months, after treatment with ZDV. Nevertheless, the increased pulmonary vascular resistance has led to tricuspid regurgitation that improves with Niphedipine. She presents recurrent mucocutaneous candidiasis, CMV + in cell culture and positive stool culture for Salmonella and Cryptosporidium without diarrhoea. The nutritional status improve at the beginning of treatment but now it's stationary. She continues - with immunological disorders, persistent polyclonal hipergammaglobulinemia and a low T$_4$/T$_8$ ratio. Serial titles of P$_{24}$ Ag have decreased since she began treatment with ZDV from 528pg/ml to 166pg/ml at the present time. We have detected a title of 16584 IgG to EBV, coinciding with a pneumonia. This title persist high at the present time.
CONCLUSION: We think treatment with ZDV has been useful in this patient, despite of the immunological deterioration and the recurrent lung infections. We base on the decrease in serum of P$_{24}$ Ag title and because she has prolonged her life 3 years, more than it was expected at the begining of the disease.

M.B.P.370 VIRAL ANTIGEN(HIV-Ag) EVOLUTION IN AIDS AND ARC PATIENTS WITH ZIDOVUDINE TREATMENT.

ME VALENCIA, R MARTINEZ ZAPICO, V PINTADO, JML DUPLA, P LAVILLA, A GIL. Hospital La Paz. Madrid. Spain.

Objective: To study the evolution of the HIV-Ag levels in AIDS and ARC patients during the treatment with Zidovudine (AZT).
METHODS: HIV-Ag was studied in 26 patients with HIV infection (18 AIDS, 8 ARC), before starting treatment and monthly during the follow up. The HIV-Ag was determined by ELISA (Pasteur). Levels of antigenaemia higher than 50 pg/ml were considered as positive. All positive sera were confirmed by a neutralization test. All patients were being treated initially with AZT 200 mg po-q4h and this dose was modified upon haematologic parameters. The mean follow-up period was 20 weeks.
Results: HIV-Ag was detected in 10 patients(38%).9 had AIDS, follow-up was completed in 8. A) 5 patients had HIV-Ag (+) before starting AZT. In 2 patients the Ag became negative in the 4th and 16th week. However HIV-Ag became positive later with levels higher than initial values. The 2 patients died in 3th and 6th month from starting therapy. In another patient Ag became negative in the 12th week and died 4 weeks later. In 2 patients Ag remained positive. One died in the 3th month of treatment and another is alive after 28 weeks of follow-up. B) In 3 patients antigenaemia was initially negative and became positive in the 4th, 28th and 32th week of AZT treatment and they are still alive.
Conclusions: AZT since to decrease initially the levels of HIV-Ag. This feature doesn't mean a better prognosis. Reappareance of HIV-Ag is a common finding after several weeks of treatment. Patients with Ag (+) prior to treatment seem to have a worse prognosis.

Clinical Manifestations

M.B.P.371 BACTEREMIA IN PATIENTS WITH HUMAN IMMUNODEFICIENCY VIRUS

Chow, Jean; Luten, I.; Thomas, G.; Garcia, M.; Ugokwe, C.; Gupta, A.
Lincoln Hospital and New York Medical College, Bronx, New York, USA.

Objective. To determine the rates and patterns of bacteremia including Nosocomial Infections (NI), in patients with Human Immunodeficiency Virus (HIV) infection.

Methods. Over a 24 month period, 462 adults with HIV infections were hospitalised. Computerized NI data for the hospitalized population and the HIV infected patients was analysed using NOSO-3 software.
Results. Forty (8.6%) episodes of NI developed in 27 (5.8%) of the 462 patients. The NI rates for the hospital and medical service were 1.9% and 1.7% respectively in the same period. Intravenous site (IV) infections occurred in 14 (52%) followed by bacteremias in 11 (41%). In 6 of 11 cases the pathogen causing bacteremias and IV site infections were similar. The NI bacteremia rate in HIV infected patients and the hospital population were 2.3% and 0.4% respectively. Mortality occurred in 13 (48%) patients during the hospitalisation when NI developed.

Interestingly, the NI pathogens isolated from the HIV infected patients and the hospital population were similar: S. aureus, 7 (29%), Acinetobacter anitratus, 5 (21%), and E. coli, 3 (11%).
Conclusion. HIV infected patients are at increased risk of secondary infections particularly, bacteremias and IV infections. Emphasis on IV site care may help in preventing these infections and perhaps the subsequent mortality.

M.B.P.372

PULMONARY TUBERCULOSIS AND HIV DISEASE IN INFANTS AND CHILDREN

Adel E.A. Malek, K. Mukelabai, E.P. Luo
University Teaching Hospital, Lusaka, Zambia.

OBJECTIVE: To determine the seroprevalence of HIV Disease in Infants and children with Pulmonary Tuberculosis, the clinical presentation and overall prognosis.
METHODS: Based on diagnostic scoring system, 96 in-patients with definite evidence of pulmonary tuberculosis were included in the study. For each patient we checked: Growth Chart, BCG Scar, and nutritional status. Physical examination and Chest X-Ray were done on admission and repeated after 2 months. Full Blood Count and ESR were done every 2nd week. Screening for anti-HIV antibodies was done using ELISA (Abbott or Wellcozyme) test. Any reaction to the antituberculous drugs (Streptomycin, Rifampicin, Thiacetazone and INH) was monitored.
RESULTS: Of 96 confirmed cases with pulmonary tuberculosis 23(24.0%) were seropositive, (peak: 1 - 2 years). While it was 3 - 5 years in the seronegative group. Twenty (87.0%) seropositive patients and 66 (90.0%) seronegative patients received BCG Vaccination. The nutritional status was poor in 19 (82.6%) seropositive and 52(71.2%) seronegative patients. Primary complex ± parenchymal lesion was found in 17 (74.0%) seropositive and 69 (94.5%) seronegative patients. Two (8.7%) seropositive and 3 (4.1%) seronegative patients had pleural effusion. Three (13.0%) seropositive and one (1.4%) seronegative patients had miliary tuberculosis. One (4.3%) seropositive patient had tuberculous meningitis with no cases in the seronegative group. Six (26.1%) seropositive and 47(64.4%) seronegative patients showed clinical improvement. One (4.3%) seropositive and two (2.7%) seronegative patients reacted to antituberculous drugs. Nine (39.1%) seropositive and 5 (6.8%) seronegative patients died during the study.
CONCLUSION: Pulmonary Tuberculosis is more aggressive when coupled with HIV Disease in infants and children. BCG Vaccination does not seem to offer significant protection against acquiring pulmonary tuberculosis.

M.B.P.373

HIV INFECTION AND TUBERCULOSIS IN MOZAMBIQUE

J.Barreto, C.Palha de Sousa, H.Djedje, L.Parkkali, L.Barquet, F.de la Cruz, F.Neves et al.
Immunology Lab.,Instituto Nacional de Saude,& Tuberculosis Control Programme,Maputo, Mozambique.

Objective: To assess HIV 1 and HIV 2 infection risk in Mozambique Tuberculosis Patients through a case-control study.
Methodology: TB patients under specific antituberculotic treatment aged more than 14 years are studied in the cities of Maputo and Nampula. A control group is being selected from blood donors matching age, sex, occupation and place of residence.Moreover TB occurrence is being actively searched and recorded in AIDS diagnosed cases.
HIV 1 and HIV 2 antibodies are screened by ELISA and those repeatedly positive, confirmed by Western Blot. Risk Ratio is estimated from the Odds-ratio using a Mantel Haenszel weighted average.
Results: Data already available reveals higher HIV infection rates among TB patients when compared with control population. Whereas, by December 1988, in 26 AIDS cases reported to WHO, 8 of them had the diagnosis of Tb (30.3%).
Conclusions: HIV infection risk seems to be high among Mozambican Tb Patients and Tb appears frequently as associated infection in AIDS cases.

M.B.P.374

HIGH CASE RATE OF EXTRAPULMONARY AND PULMONARY TUBERCULOSIS IN HIV INFECTED IN UPPER AUSTRIA

Simader, Renate,Geit,M.Pfeifer,W.
General hospital Linz, Upper austria, Austria

From 3/1985 to 1/1989 more than 30 % of all AIDS patients first presented with extrapulmonary tuberculosis (tb-adenitis, tb-meningitis or miliary tuberculosis).
In all of them, except one woman who died of infection with mycobacterium avium intracellulare, mycobacterium tuberculosis could be isolated and in vitro sensitivity testing could be done (results will be shown). Except one heterosexually infected woman and one man with unknown risk all patients belonged to the high risk group of intravenous drug abusers. The median range of CD4 cells in those patients was higher compared with AIDS patients suffering from other opportunistic infections.
In patients with LAS/ARC pulmonary tb was seen in 4 %.

Results of intracutaneous skin testing (we consider important in differential diagnosis to lymphoma) will be presented as well as the median survival rate of AIDS patients with extrapulmonary tb or the time to progression to AIDS in the others.

M.B.P.375

PREDICTORS OF MORTALITY IN PATIENTS WITH AIDS AND PNEUMOCYSTIS CARINII PNEUMONIA (PCP).

Krumholz, Harlan M.; Sullam, P.M.; and Tager, I.B.
Veterans Administration Medical Center (VAMC), San Francisco, and the University of California, San Francisco, CA, USA.

Objective. To identify the clinical and laboratory features on admission to hospital that are predictive of mortality in patients with AIDS and PCP.
Methods. We reviewed retrospectively the charts of all patients with AIDS and PCP admitted to the VAMC between January 1984 and August 1987. The respiratory rates, white blood cell counts (WBC), serum albumin concentrations, and arterial blood gases of survivors and nonsurvivors were compared.
Results. Fifty cases of PCP were identified, of which 35 survived hospitalization. On admission, survivors were significantly less tachypneic than nonsurvivors (mean respiratory rate ± S.D. = 21.7 ± 4.8 vs. 28.4 ± 8.0 breaths/min; $P<0.01$). The mean arterial pO_2 on admission was significantly higher ($P<0.01$) in survivors (69.0 ± 16.0 mm Hg) than in nonsurvivors (55.3 ± 11.2 mm Hg). Moreover, of 13 patients with $pO_2 \geq 75$ mm Hg, none died ($P<0.01$, when compared with the survival rate for $pO_2 < 75$). Severe hypoxia was not correlated with a poor outcome; all 3 patients with a pCO_2 <40 mm Hg survived. The WBC, serum albumin levels, arterial pCO_2 and pH were comparable in survivors and nonsurvivors.
Conclusions. In patients with PCP, an arterial $pO_2 \geq 75$ mm Hg on admission is associated with increased survival. By identifying patients with a good prognosis, the pO_2 may help select candidates for shortened hospitalizations or outpatient therapy.

M.B.P.376

RESULTS OF A CONSENSUS PANEL ON PROCESS OF CARE FOR PATIENT. WITH PNEUMOCYSTIS CARINII PNEUMONIA (PCP).

C. BENNETT, WC MATHEWS, J KOSECOFF, D KANOUSE, RAND Corporation, Santa Monica, Ca, UCLA Med Center, LA; UCSD Med Center, SD, Ca USA

Objective: To develop consensus opinions for defining process of medical care for the entire episode of illness for patients with PCP.

Methods: As part of a research study aimed at evaluation of quality of care for AIDS pts w/PCP, seven AIDS specialists with training in various specialties (Int Med,2; Pulmonary-1; Infectious disease-3; Immunology-1) evaluated process of care and clinical factors for treatment of PCP.

Results: Panelists agreed on: criteria for identification from the medical record of an initial episode of PCP, appropriate diagnosis, definitions of pulmonary severity and extrapulmonary comorbidity; and appropriate antimicrobial and adjunctive pharmacologic treatment and other process of care markers. Panelists also agreed on appropriate indications for out-pt therapy, clinical markers of response to initial treatment, and a temporal window for evaluating treatment response.

Conclusion: A panel reached consensus on many aspects of care that may be helpful in evaluating quality of medical care for the entire episode of illness related to PCP (pre-hospital, in-hospital, and post-hospital care) and might predict outcomes for episodes of PCP. These results will be presented at the conference.

M.B.P.377

SPLENIC PNEUMOCYSTOSIS

Piot, Didier; Gathe, J.; del Junco, G.; Stool, E.; Trujillo, R.
Park Plaza Hospital, Houston, Texas, U.S.A.

Objective: To describe splenic involvement with Pneumocystis Carinii (PC) as a manifestation of extrapulmonary pneumocystosis in the absence of clinical PCP.
Methods. A 27-year-old white, male homosexual was diagnosed with AIDS when he developed Candida esophagitis in October 1987. He had been maintained on AZT and twice monthly aerosolized pentamidine, when he presented with vague pleuritic left lower chest and abdominal pain and fever of 103.0 F. 12 months later. He initially responded to broad spectrum antibiotics, but his fever returned when they were discontinued.
Results. PE was remarkable only for a palpable spleen tip. Chest x-ray and gallium scan were normal. A CT scan of the abdomen showed multiple splenic masses. Splenectomy revealed multiple large masses of PC by GMS stain. Multiple microscopic foci of PC were also present and confined to the red pulp, confirming hematogenous dissemination. The white pulp showed lymphoid depletion. He responded well to pentamidine. Postoperative atelectasis lead to bronchoscopy with transbronchial biopsy and bronchoalveolar lavage which were negative for PCP.
Conclusions. 1. Although PCP is the most common opportunistic infection in AIDS, extrapulmonary pneumocystosis is rare.
2. Extrapulmonary pneumocystosis can occur in the absence of clinically evident PCP.
3. PC can spread to extrapulmonary sites via hematogenous or lymphagenous routes. Risk factors for dissemination remain unclear.
4. The spleen may be a site at risk for extrapulmonary pneumocystosis because of its filtration function.
5. To predict more cases of extrapulmonary pneumocystosis in patients who receive only pulmonary prophylaxis.

M.B.P.378 DISSEMINATED GRANULOMATOUS PNEUMOCYSTOSIS IN A PATIENT RECEIVING AEROSOLIZED PENTAMIDINE PROPHYLAXIS

Ward, Douglas J. George Washington University School of Medicine, Washington, D C

A 35 year old gay male had Pneumocystis pneumonia in 5/87. He was maintained afterwards on AZT plus aerosolized pentamidine prophylaxis. In 9/88 he again developed weight loss, chronic fevers and dyspnea, and was admitted with a spontaneous pneumothorax. Pneumocystis was diagnosed by bronchoscopy, and he was treated with pentamidine, which was switched to trimethoprim/dapsone because of renal failure. His status progressively deteriorated, complicated by renal failure, seizures, diarrhea and edema, and he died of respiratory insufficiency after two weeks. On autopsy he was found to have disseminated granulomatous Pneumocystis involving the lung, heart, lymph nodes, liver, spleen, GI tract, adrenal and thyroid glands and choroid, as well as disseminated cytomegaloviral inclusions.

There have been 17 cases of extrapulmonary pneumocystis reported in the literature, six of these in patients with AIDS. Only four of these, however, have been truly disseminated with multiple organ involvement (one with AIDS). This patient may have predisposed to disseminated disease because of his use of aerosolized pentamidine, which suppresses infection in the lungs, but has no extrapulmonary effect. As this form of prophylaxis becomes more widespread, extrapulmonary pneumocystis may become more common.

M.B.P.379 *PNEUMOCYSTIS CARINII* CHOROIDITIS

Cassey, D.M., Rao, N.A., and Zimmerman, P.L.
University of Southern California and the Estelle Doheny Eye Institute, Los Angeles, California, USA

Objective. To describe highly characteristic clinical features and light and electron microscopic findings of *P. Carinii* choroidal infiltrates in three patients with AIDS.
Methods. Three patients were followed antemortem for AIDS-related conditions; two had Cytomegalovirus retinitis treated with ganciclovir. New choroid lesions developed and retinal photographs were obtained. At autopsy, the globes of the eyes were examined grossly, by light microscopy and by electron microscopy.
Results. The characteristic fundus changes in *P. carinii* choroditis consist of multiple slightly elevated, plaque-like, yellow-white lesions in the choroid. Some of these choroidal lesions are round or oval, while others are geographic or multilobulated in shape. The lesions vary in size and are usually covered by relatively normal retinal pigment epithelium. However, some of the larger lesions may show areas of mild retinal pigment epithelial alteration consisting of fine mottling or granular change. The fundus changes are not associated with intraocular inflammation. The etiology of the fundus pathology was determined by electron microscopy demonstrating P. carinii organisms.
Conclusions. *P. carinii* can produce characteristic funduscopic changes in the choroid and such findings can indicate disseminated *P. carinii* infection.

M.B.P.380 INCIDENCE OF PNEUMOCYSTIS CARINII PNEUMONIA (PCP) IN MEN INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS-1 (HIV-1)

Phair, John, Muñoz, A., Detels, R., Rinaldo, C. and Saah, A., Multicenter AIDS Cohort Study, Chicago, IL.

Objective: To determine the risk of developing PCP in homosexual men infected with HIV-1.
Methods: 1744 seropositive homosexual men were enrolled into a prospective study of HIV-1 infection in 1984-85. A history, physical examination and T-cell phenotyping were obtained every 6 mo. Outcomes through 7/31/88 are included in the analysis.
Results: Of 1660 men with available baseline CD4 counts, 185 developed PCP. This table stratifies outcome over 3 years by CD4 number at entry.

CD4 Count	N	PCP	6 mo.(%)	12 mo.(%)	36 mo.(%)
0-200	78	22	8.3	17.9	38.2
200-350	231	53	0.4	3.7	24.1
350-500	391	43	0.0	1.3	9.5
500-700	479	46	0.0	0.4	9.0
>700	487	21	0.0	0.0	4.1

Among participants whose CD4 count cell decreased to $200/mm^3$ at some time during the study, weight loss and thrush significantly ($p \leq 0.01$) increased risk at 6, 12 and 36 months; fatigue and fever were predictive ($p \leq 0.01$) for short term (less $\leq$ 12 mo) development of PCP. Diarrhea, herpes zoster or hairy leukoplakia were not predictive.
Conclusion: Risk of developing PCP significantly ($p \leq 0.001$) increased with decreasing CD4 cell count. Specific signs and symptoms occurring in immunosuppressed participants significantly add to the risk of PCP.

M.B.P.381 PSYCHIATRIC MORBIDITY IN HIV INFECTED INDIVIDUALS IN INDIA

JACOB,K.S., MOSES,H., JOHN,J.K. AND JOHN,T.J.
Christian Medical College,Vellore,India.

Objective. To document the psychiatric morbidity among HIV carriers and AIDS victims.

Method. 24 subjects were assessed to document psychiatric morbidity.The diagnosis of HIV infection/AIDS was communicated in the context of the psychotherapeutic support provided.They were followed up for a period of 2 to 6 weeks and additional psychopathology documented.DSM-III criteria were used for diagnosis.
Results.Psychiatric morbidity at initial screening included Delirium(1),Major Depressive Disorder(1),Adjustment Disorder with depressed mood(7),and Marital discord(1).After the diagnosis of HIV infection was communicated the additional morbidity included Adjustment Disorder(3),Major Depression(1),Alcohol Dependence Syndrome(2) and Suicide(1).The individual who reacted with Major Depression also developed alcohol dependence and he committed suicide.
Discussion.The possibility that preexisting psychopathology predisposed these individuals to sexual promiscuity needs to be explored.The majority of individuals reacted with depression and could be supported through the crisis.

M.B.P.382 PREVALENCE AND COURSE OF PSYCHIATRIC DISTURBANCES ASSOCIATED WITH HIV INFECTION (CDC CATEGORIES II-IV)

Boom, Frans van den*; Sno, Herman**; Storosum, Jitsak**
* Netherlands Institute of Mental Health, Utrecht, The Netherlands. **University of Amsterdam, Dept. of Psychiatry, Amsterdam, The Netherlands

Objective: Gain insight in the prevalence and course of psychiatric distubances/disorders in HIV infected persons
Method: Every newly registered patient in a period of one year at the Academical Medical Centre (AMC) in Amsterdam will be followed during 12 months. A psychiatrist will give a DSM III R diagnosis at entrance, and after 6 and 12 months; a neurological examination will be executed at entrance; a psychiatric interview using the Diagnostic Interview Schedule will be held at entrance and 12 month later; with a bimonthly frequency several self report questionnaires (General health Questionnaire, Beck's Depression Scale) will be filled out, a neuropsychological test battery will be administered, and a 10 minute interview will be held.
For those who need psychiatric treatment, interventions and complications (eg with medication) will be monitored and registered. Special attention will be payed to organic complications.
Results: Preliminary results will be presented.

M.B.P.383 DIAGNOSIS OF DEPRESSION IN HIV INFECTED INDIVIDUALS

Hong, B.A.,; Rice, J; Brookshire, D. and Guedet, P.

AIDS Clinical Trials Unit, Washington University School of Medicine, Saint Louis, Missouri, USA.

OBJECTIVE. To examine the presence and course of depression in HIV infected individuals.
METHOD. A random sample of 26 seropositive individuals, 10 ARC and 10 AIDS patients who were enrolled in an AIDS Clinical Trial Unit were evaluated for depression by means of a standard psychiatric research interview. The SADS-L (Schedule For Affective Disorders and Schizophrenia-Lifetime) was used. Diagnoses were made by RDC (Research Diagnostic Criteria) criteria. Subjects were interviewed on the average of 15 months post HIV testing.
RESULTS. Fifty percent (N=23) met criteria for a depressive diagnosis during the interval from HIV testing to the time of the present assessment. Forty percent (N=18) experienced a major depression which lasted a week or longer. Ten percent experienced a minor depression. Twenty-one percent (N=10) had suicide ideation or death wish. Two subjects attempted suicide. Depression appeared to be less frequent one year or greater after HIV testing, as only two subjects reported current problems with major depression and three with minor depression.
CONCLUSION. It is noteworthy that half of the sample had a clinically significant depression. Further, depression appears to be less common as individuals have time to cope with their HIV status.

M.B.P.384 PREVALENCE DES TROUBLES PSYCHIATRIQUES PARMI LES PATIENTS HOSPITALISES POUR SIDA.

Zamperetti Marco*;Ferrazzi D.**;Schlacht I.**;Cusini M.***;Muratori S.***;
Zerboni R.***
*Servizio Psichiatrico "Origgi I"(Responsabile Prof.G.F.Goldwurm); **Reparto Infettivi Adulti (Responsabile Prof.F.Giannelli) - Ospedale Cà Granda Niguarda - Milano - ITALY
***Clinica Dermosifilopatica dell'Università degli Studi di Milano (Responsabile Prof.R.Caputo)

Objective. Plusieurs auteurs ont trouvé une prévalence des troubles psychiatriques,parmi les sujets infecté de l'HIV à different stade,qui oscille entre le 30% et le 50% selon l'étude.Nous avons voulu vérifier si cette donnée on peut la retrouver aussi parmi nos patients.
Méthodes. Nous avons pris en considération la population des sujets hospitalisés en maladies infectieuses à l'hôpital de Niguarda à cause de l'HIV. Depuis deux ans,parmi ces patients,on a observé la prevalence et les principaux aspects anamnestiques et cliniques des ceux qui avaient presenté des troubles psychiques.
Résultats. Les patients hospitalisés pour SIDA en 19 mois ont été 125,dont 107 (85,6%)mâles et 18 (14,4%)femelles;l'âge moyen a été 28,2a.. Parmi les facteurs de risque,l'utilisation des drogues a representé le 76,2%,l'homosexualité le 11%,les transfusions le 8,4% et les rapports hétérosexuels le 4,2%. La prévalence des troubles(t.) psychiques a été du 37,6%(47/125)dont les t. mentaux organiques étaient le 42,6%(20/47),les t. de l'humeur le 14,9%(7/47),les t.de l'adaptation le 12,8%(6/47),les t.de la personnalité le 8,5%(4/47),les t.d'anxiété le 8,5%(4/47),les schizophrénies le 4,2%(2/47) et enfin les t.psychotiques pas classés ailleurs le 8,5%(4/47).
Conclusions. Notre étude semble confirmer les travaux d'autres auteurs,soit pour la prévalence des troubles psychiques,soit pour le pourcentage des t. mentaux organiques.

Traitement de la PCP : Pentamidine et autres médicaments (diagnostic clinique)
PCP Treatment: Pentamidine and Other Drugs (Clinical Diagnosis)

T.B.P.1

EVALUATION QUANTITATIVE DU PARASITISME AU COURS DE LA PNEUMOCYSTOSE (PNCP) CHEZ LES PATIENTS ATTEINTS DE SIDA OU D'AUTRES IMMUNODEPRESSIONS.

ROUX Patricia, PARROT A., DENIS M., MAYAUD C., PARQUIN F., LANCASTRE F.
Hôpital TENON - 4, rue de la chine - 75020 - PARIS

Objectif : Rechercher si, comme pour l'expression clinique, il existe une différence dans l'intensité du parasitisme au cours des pneumocystoses survenant chez les sujets atteints de SIDA ou d'autres immunodépressions.
Méthodes : Cette étude concerne 80 patients : 67 SIDA (G1) et 13 autres immunodéprimés (G2); tous ont une pneumocystose diagnostiquée par lavage bronchiolo-alvéolaire (LBA), 29 ont une insuffisance respiratoire aiguë (IRA) avec PaO2 <50 mmHg. L'intensité du parasitisme a été évaluée sur le nombre d'amas présents dans 10 µl du culot de centrifugation du LBA selon une méthode semi-quantitative : parasitisme faible + à ++, intense +++ à +++++.
Résultats :

	G1		G2	
Parasitisme	faible	intense	faible	intense
PaO2<50 mmHg n = 26	0	19	7	0
PaO2>50 mmHg n = 54	16	32	5	1

Conclusions : Il existe des différences d'intensité du parasitisme dans les deux populations étudiées en particulier au cours des PNC.P sévères avec IRA : parasitisme intense dans G1, faible dans G2.

T.B.P.2

FINAL DIAGNOSIS IN PATIENTS WITH NEGATIVE BRONCHO-ALVEOLAR LAVAGE FOR PNEUMOCYSTIS.

Slim, Jihad*, Perez, G., Forrester, C., Shafii, A., Johnson, E.S.
Saint Michael's Medical Center, Newark, New Jersey, U.S.A.

Objective: To attempt and determine a final diagnosis in patients with a negative Broncho-Alveolar Lavage (BAL) for PCP.
Methods: Review of all hospital charts of HIV positive patients with bronchoscopy for suspected PCP. Further analysis of those charts with negative PCP on BAL included clinical symptoms, laboratory examinations, chest x-rays and gallium scans.
Results: 88 HIV positive patients underwent 93 bronchoscopies with negative silver methenamine stains for PCP. 13 of these events were felt to be PCP, these included five with positive results on transbronchial biopsy and eight with a compatible laboratory and clinical course. 22 were found to have positive mycobacterial cultures, seven of which were M. tuberculosis. Right sided endocarditis with embolic pneumonia accounted for six cases, 5 had positive fungal cultures and another five showed CMV. Seventeen remained without an etiologic diagnosis.
Conclusion: Most patients with suspected PCP with negative silver stains on BAL had an etiologic agent identified. These agents were usually treatable.

T.B.P.3

A PATHOLOGIC BASIS FOR BRONCHOALVEOLAR LAVAGE (BAL) NEUTROPHILIA IN PNEUMOCYSTIS CARINII PNEUMONIA (PCP).

Mason, Gregory R, Foutty LL, and Dickman PS. Harbor-UCLA Medical Center, Torrance CA, 90509, USA.

Objective. In 60 patients with PCP, > 5% BAL neutrophils predicted morbidity more sensitively and specifically than the degree of hypoxemia, hypoalbuminemia or increased LDH (Am Rev Resp Dis, in press). We sought to determine a pathologic basis of excess bronchoalveolar lavage (BAL) neutrophil percentages in Pneumocystis carinii pneumonia.
Methods. Transbronchial biopsies of 29 patients with documented PCP and specimens adequate to assess the histology the lung parenchyma were reviewed. Biopsies were scored from 0 (absent) to 3 (easily found in most fields) for the degree of diffuse alveolar damage (DAD) and for the presence of polymorphonuclear leukocytes (PMN's) as well as the presence of organisms, edema, chronic inflammation, fibrosis and intra-alveolar or interstitial PMN's.
Results. The presence of DAD and interstitial or intra-alveolar PMN's were the most common abnormalities in the lung parenchyma and each was found in 27 of 29 patients. The presence of fibrosis was the least common finding, present in only 6 of 27 patients.
Conclusions. DAD and neutrophilic infiltration were commonly found in the transbronchial lung biopsies in patients with AIDS. Neutrophilic infiltrates are not a well-recognized sequelae of PCP, however, PMN's in the lung may account for more severe clinical manifestations of this disease and provide the basis for staging of PCP with BAL neutrophils.

T.B.P.4

INTERET ET LIMITES DES EXPECTORATIONS INDUITES DANS LE DIAGNOSTIC DE LA PNEUMOCYSTOSE DU SIDA.

Delacour, Thierry* ; Roux, P.* ; Camus, F**. ; Fay, M.*** ; Denis, M.* et Girard, PM.***
*Hôpital Tenon, Paris, France ; **Hôpital Claude Bernard, Paris, France ; ***INSERM U13, Paris, France.

Objectif. Evaluation diagnostique de l'expectoration induite (EI) comparée au lavage bronchioalvéolaire (LBA).
Patients et méthodes. Un recueil d'EI et de LBA a été fait simultanément chez 132 patients HIV positifs suspects de pneumocystose dont 23 hospitalisés en soins intensifs. Des examens itératifs ont été faits chez 17 patients. EI : recueil après induction par un aérosol salé hypertonique (3 %) avec l'aide d'un kinésithérapeute. LBA : selon la technique habituelle.
Traitement des prélèvements : fluidification des EI (dihydroxydithiolbutane) puis centrifugation - colorations par Giemsa, impregnation argentique et/ou Bleu de Toluidine O et/ou Gram Weigert. la lecture des lames codées a été faite par deux examinateurs.
Résultats.

Service	LBA (%)	E I (%)	Sensibilité E I/LBA (%)
Maladies Infectieuses	50 / 120 (42)	32 / 120 (27)	32 / 50 (64)
Soins intensifs	16 / 31 (52)	4 / 31 (13)	4 / 16 (25)

Conclusion. 1) Spécificité des EI : 100 %. 2) Sensibilité des EI plus faible chez les patients de soins intensifs (25 % versus 64 %) probablement due au traitement anti Pneumocystis administré pendant plus de 7 jours dans cette série. 3) L'induction des expectorations s'est révélée impossible chez 20 % des patients. 4) Au total, chez des patients ne recevant pas de traitement anti Pneumocystis, le recueil du LBA pourrait être évité dans 24 % des cas.

T.B.P.5

ANTIBODIES TO PNEUMOCYSTIS CARINII. REDUCED LEVELS IN HIV INFECTED PATIENTS DURING PNEUMOCYSTIS INFECTION AND EVALUATION OF PASSIVE IMMUNISATION.

Burns, Sheila M.*; Read,J.A.*; YAP, P.L.**; Brettle, R.P.***.

* Regional Virus Laboratory, City Hospital, Edinburgh, Scotland.
** Scottish National Blood Transfusion Service, Edinburgh, Scotland.
*** Infectious Diseases Unit, City Hospital, Edinburgh, Scotland.

Objective. To follow the relationship between P.carinii antibody levels and acute infection in sequential samples from HIV antibody positive patients with respiratory symptoms and to investigate the possibility of using immunotherapy.

Methods. Using an IFA based on frozen sections of infected rat lung, P.carinii antibody estimations were performed on 38 HIV positive patients and 37 HIV negative immunocompromised patients with respiratory symptoms. Multiple samples from 25 symptomatic positive patients were examined and the P.carinii antibody level correlated with available bronchoalvolar lavage or induced sputum results.

Results. Five patients with proven P.C.P. had an acute fall in antibody level and a further 3 showed recovery of antibody following diagnosis and treatment. The same pattern was observed in those patients with suspected but not proven P.C.P. Antibodies to other viruses and serum immunoglobulins did not show a similar pattern. The P.carinii antibody level in 40 blood donors and in intravenous globulin (IVG) samples selected at random was estimated.

Conclusion. The use of IVG in acute infection with P.carinii and as prophylaxis against infection either alone or in conjunction with other therapeutic agents, is worth further evaluation.

T.B.P.6

PURIFICATION AND CHARACTERIZATION OF A MAJOR HUMAN PNEUMOCYSTIS CARINII SURFACE ANTIGEN

Lundgren, Bettina; Lipschik, G.; and Kovacs, J.A.
National Institutes of Health, Bethesda, Maryland, USA.

Objectives. Purified Pneumocystis carinii (PC) antigens are needed for investigations into host-organism interaction and host immune responses following infection. Since human and rat PC are antigenically different, antigens of human PC should be used in such studies. The goal of the current study was to purify a major antigen of human PC.
Methods. PC were obtained from autopsy lungs of patients that died of PC-pneumonia. Organisms were treated with zymolyase, a ß-1,3-glucanase, and the antigen was purified by HPLC using a sizing column followed by ion-exchange chromatography. To evaluate the size of the native molecule, a cross-linking study using bis(sulfosuccinimidyl)substrate (BS³) was done.
Results. Zymolyase treatment of PC solubilized the predominant antigen, which has a size of 95,000 MW when evaluated by SDS-polyacrylamide gel electrophoresis under reducing conditions. This antigen reacts with a monoclonal antibody (6B8) previously shown to be specific for human PC; immunofluorescence studies have shown that it binds to the surface of PC. Reactivity with the monoclonal antibody was used to follow purification. The size of the native molecule, based on sizing column chromatography, was greater than 290,000 MW. Following ion-exchange chromatrography, a single band of 95,000 MW was seen on SDS-PAGE, and this band reacted by immunoblot with antibody 6B8. Cross-linking of the molecule prior to SDS-PAGE suggests that the antigen is a trimer, based on the presence of a new 270 000 MW antigen on SDS-PAGE that also reacted by immunoblot with 6B8.
Conclusion. A major surface antigen of human P. carinii with a molecular weight of 95,000 under reduced and denatured conditions has been purified to homogeneity. This purified antigen can be used to develop assays to investigate the cellular and humoral response of humans to PC infection.

T.B.P.7

THE DIAGNOSIS OF PNEUMOCYSTIS CARINII PNEUMONIA IN HIGH RISK PATIENTS BY INDUCED SPUTUM USING A DIRECT IMMUNOFLUORESCENT ANTIBODY TEST

Heath-Chiozzi, Margo; Mitchell,M.; Rosol-Donoghue,J.; Cotton,D.; Hulme,P.; Hanff,P. Beth Israel Hospital, Harvard Medical School, Boston, MA, USA.

Objective. Evaluation of the Genetic Systems direct immunofluorescent monoclonal antibody test (DFA) to detect *Pneumocystis carinii* in induced sputum.

Methods. Induced sputum (IS) was collected from 27 patients who were HIV seropositive or in a high risk group and had interstitial infiltrates on chest x-ray, room air $PO_2 \leq 80$, and/or a positive Gallium scan. Bronchoalveolar lavage (BAL) was performed on most patients whose IS was nondiagnostic. IS and BAL were processed using published techniques and stained by Toluidine Blue O (TBO) and DFA. TBO smears with heavy yeast were considered uninterpretable (TBOU). Slides with ≥3 cysts were considered positive.

Results. There were 16 DFA positive IS smears of which 8 were also TBO +, 4 were TBOU and 4 were TBO -. Six of these 8 patients who were DFA + but TBOU or TBO - were confirmed to have pneumocystis pneumonia (PCP) by BAL whereas 2 patients refused BAL; 1 had a clinical course consistent with PCP, the other was lost to follow-up. Eleven IS smears were DFA negative; 10 were TBO - and 1 was TBOU. Six of these were confirmed negative by BAL. Of the 5 remaining patients who did not go on to BAL, 3 improved without specific PCP therapy, 1 had been reinduced to rule out a PCP treatment failure, and a final clinical diagnosis could not be made in 1 patient due to concomitant PCP and antibacterial therapy.

Conclusion. In patients at high risk for AIDS-related PCP, DFA is more sensitive than TBO and makes the diagnosis of PCP by induced sputum a simple, rapid, and highly sensitive test.

T.B.P.9

A MEASURE OF PNEUMOCYSTIS CARINII PULMONARY BURDEN.

Baughman Robert P, Frame PT.Department of Medicine, University of Cincinnati, Cincinnati, OH, U.S.A.

Objective. To develop a method for estimating the burden of *Pneumocystis carinii* (Pc) in bronchoalveolar lavage (BAL) fluid of AIDS patients (pts). Methods. BAL fluid from AIDS pts with Pc pneumonia were prepared with a cytocentrifuge and a modified Wright-Giemsa stain. The number of Pc in clusters was compared to the number of nucleated cells counted. Intra- and intersubject variability was determined by analysis of variance and the F-ratio (F) and p values calculated. Results. Pc clusters from BAL specimens of 20 pts were counted three times. The cluster number that was associated with 200, 500, and 1000 cells was noted. There was significant intersubject variability for the 200, 500, and 1000 cells (200 cells: F=9.0; 500 cells: F=13.3; 1000 cells: F=16.8, all p<0.001). The correlation coefficient for 500 cells between counts (R=.81, p<0.001) was higher than 200 cell counts, but similar to 1000 cell counts; the number of clusters with 500 cells was used thereafter. Because the BAL fluid volume may alter the cell differential, we studied BAL specimens aspirated after each of four introduced aliquots of 60 ml saline in 15 Pc pts. There was no significant intrasubject variability (F=.10,p=N.S.), but there was significant intersubject variability (F=53.7, p<0.0001). Sequential lavage specimens from 24 pts before (PRE) and after (POST) therapy for Pc pneumonia were studied. Sixteen pts responded to therapy; all had a decrease in Pc clusters (PRE=5.4±1.1 (Mean±S.E.M.); POST=.4±.2, p<0.001). Eight pts had persistent disease; the BAL contained the same or more Pc (PRE=5.2±1.6; POST= 5.5±1.6). Conclusion. Pc can be quantitated in BAL fluid; this may be useful in assessing therapy.

T.B.P.11

Rapid Diagnosis of Pneumocystis carinii pneumonia (PCP) in Patients with AIDS using a Direct Fluorescent Monoclonal Antibody (DFA) Assay.

Virani-Nzeeg*; Ng VL**; Chaisson RE*; Hadley WK**; Sphar HT*; Yajko D** and Hopewell PC**, U.S.A.
* Johns Hopkins Hospital, Baltimore, Maryland, ** San Francisco General Hospital, San Francisco, California.

Objective: To compare a new DFA (Genetic Systems) with a Giemsa (Diff-Quick) for the diagnosis of PCP from sputum and bronchoalveolar lavage (BAL).

Methods: Induced sputum from patients with suspected PCP was digested, centrifuged and smeared onto slides. Heat fixed Giemsa and acetone fixed DFA stained slides were examined for trophs and cysts. BAL was done on patients negative by sputum, when possible.

Methods: Of 111 patients evaluated, a total of 60 were diagnosed with PCP, 52/60 with Giemsa on sputum (87% sensitivity) and 51/60 on sputum with DFA (85% sensitivity). 5 patients had PCP diagnosed by both methods on a subsequent sputum after treatment of a bacterial superinfection. 8/32 patients negative on sputum induction were positive by both DFA and Giemsa as were 3 additional patients who had BAL alone. Of the 30 patients that did not go to bronchoscopy, other diagnoses became apparent in 18 and 7 remained indeterminate. There was one false positive and one false negative DFA sputum assay.

Conclusion: This DFA is a rapid and sensitive method of identifying *P. carinii* in sputum and bronchoscopy specimens and is comparable to the standard high yield Giemsa stain.

T.B.P.8

BRONCHOALVEOLAR LAVAGE (BAL) CMV CULTURE POSITIVITY (CMV+) IS ASSOCIATED WITH BETTER OUTCOME OF PNEUMOCYSTIS CARINII PNEUMONIA (PCP) IN MEN WITH AIDS.

Arcia, JM; Bozzette, Samuel A; Bartok, A; McCutchan, JA; Richman, DD; Spector, S. UC San Diego and The California Collaborative Treatment Group, San Diego, CA, U.S.A.

Objective: To determine the significance of CMV+ in confirmed PCP.
Methods: Retrospective cohort study of all patients undergoing bronchoscopy at UCSD for possible PCP between 1/1/85 and 12/31/87. CMV+ and CMV- patients were compared for prognostic factors at presentation and for outcome. Unfavorable outcomes were death within 30 days and intubation.
Results: Of 248 episodes, 136 were confirmed PCP. All had BAL fluid viral culture; 122 were uncontaminated and evaluable. Ten cases in women (1 CMV+) were excluded. Analysis of the remaining 112 cases showed:

PRESENTATION	Number	Age	1st PCP	PaO2	ABNL CXR	Hgb	LDH
BAL-CMV+ (%)	52 (46)	x=34	42 (81)	x=68	52 (100)	x=12	x=414
BAL-CMV- (%)	60 (54)	x=34	45 (75)	x=68	60 (100)	x=12	x=487

OUTCOME	Death	Intubation	Death or Intubation
BAL-CMV+ (%)	6 (12)	4 (08)	7 (13)
BAL-CMV- (%)	13 (22)	13 (22)	20 (33)
Rel Risk (C.I.)	.53 (.22-1.27)	.34 (.08-1.09)	.40 (.20-0.84)
	p = n.s.	p < 0.05	p < 0.02

Conclusion: Nearly 1/2 of men with PCP had BAL CMV+. CMV+ men had similar presentations but apparently better outcomes than CMV- men. CMV-mediated immunosupression may reduce lung injury in PCP or CMV+ men may have underlying lung dysfunction and present with earlier PCP.

T.B.P.10

DEFECTIVE PERIPHERAL OXYGEN UTILIZATION IN AIDS PATIENTS WITH RESPIRATORY FAILURE DUE TO PNEUMOCYSTIS CARINII.

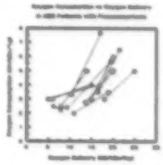
Wood, Robert D.; Ahl,B.; Tuchschmidt,J.; Swinney,R.S.; Boylan,C.T.
LAC/USC Medical Center, GH 11-900, 1200 North State Street, Los Angeles, CA 90033, U.S.A.

Objectives: A peripheral defect in oxygen utilization has been well described in septic shock and the Adult Respiratory Distress Syndrome (ARDS). Some have suggested that inadequate levels of oxygen transport to peripheral tissues may contribute to the mortality seen in these diseases. In this study we examined peripheral oxygen utilization in AIDS patients with severe respiratory failure secondary to *Pneumocystis carinii* infection (PCP).

Methods: We evaluated twelve patients (age = 34+/-8 yrs) with AIDS, documented PCP and severe respiratory failure (FIO2 = 0.86+/-0.16) requiring PEEP. We chose subjects who had no evidence of any concomitant bacterial, fungal, mycobacterial or viral infection as affirmed by lack of clinical site and negative cultures, including blood. Cardiac outputs were obtained by thermodilution and oxygen consumption calculated by the Fick equation.

Results: Our data showed

	CI	HgB	DO2I	VO2I	LACTATE
Init	4.3 + 1.1	10 + 1.7	539 + 164	152 + 65	2.4 + 1.1
12Hr	4.3 + 1.7	10 + 1.5	544 + 249	145 + 49	2.5 + 0.7
24Hr	4.4 + 1.9	10 + 1.5	546 + 304	138 + 55	4.4 + 1.9



Conclusion: Our patients with PCP and respiratory failure had a supply dependent oxygen consumption at higher levels of oxygen delivery than have been found in normal humans, suggesting a systemic defect in oxygen utilization similar to that seen in bacterial sepsis and ARDS. This may be significant with respect to management.

T.B.P.12

FREQUENT INABILITY TO CONFIRM THE DIAGNOSIS OF PRESUMPTIVE PNEUMOCYSTIS CARINII PNEUMONIA (PPCP).

Bozzette, Samuel A; Sattler, F; Chui, J; Gluckstein, D; Coffman, J; Hewlett, C. UC San Diego, U Southern Cal, UC Irvine, Kaiser/Sunset Hospital and The California Collaborative Treatment Group, San Diego, CA, U.S.A.

Objective: To assess the reliability of the diagnosis of PPCP and the utility of clinical assessment in distinguishing confirmable cases.
Method: The presentation and course of persons with PPCP was examined. All were patients enrolled into a randomized trial of corticosteroids which required subsequent confirmation of diagnosis. Only patients who had a positive induced sputum or underwent bronchoscopy were included.
Result: PCP was confirmed in 158 of 202 patients (78% pos and 22% neg).

Finding	% of PCP+ (Sensitivity)	% of PCP- (False Pos Rate)	Pos Predict Value	Neg Predict Value
Cough	91	84	79	32
Fever	87	75	81	36
Exert Dyspnea	93	84	80	39
Rest Dyspnea	61	46	83	28
Chest Tightness	56	57	78	21
PaO2 < median (65)	52	41	82	25

The pretest and posttest probabilities of disease were not significantly different for all findings and combinations of findings (not shown).
Conclusion: The diagnosis of PPCP frequently cannot be confirmed. Confirmable and unconfirmable PPCP present similarly. No finding alters the probability of confirmable disease to a clinically relevant extent. Actions based on a diagnosis of PPCP must be undertaken with caution.

T.B.P.13

A NEW METHOD FOR THE DIAGNOSIS OF PNEUMOCYSTIS CARINII IN BRONCHOALVEOLAR LAVAGE

Annick DATRY*, I. Hilmarsdottir*, P. Deletoille**, C. Katlama*, M. Danis*, M. Gentilini*.
*Dpt of Public Health, Parasitology and Tropical Medicine, Hôpital de la Salpêtrière, Paris, France, et Unité INSERM 313, Paris
**Diagnostic Pasteur, Marne-la-Coquette, France.

Objective. An indirect fluorescent-antibody technique is compared to a traditional silver staining method for the diagnosis of Pneumocystis carinii (P.c) cystes in bronchoalveolar lavage (BAL) specimens.
Methods. 200 BAL specimens from 140 patients are treated simultaneously with the indirect fluorescent-antibody technique (Detect IF P. carinii**) and Musto's rapid silver staining method.
Results. Of the 200 samples, 73 are positive for P.c., both method included. 90,4% of the positive sample are diagnosed by the indirect immunofluorescence (IIF) method and 80,8% by Musto's technique.
Conclusion. The IIF method permits again in the diagnosis of P.c. in BAL, especially when samples contain a small number of cysts. The technique is simple in performance and has the advantage of an easy and a rapid lecture.

T.B.P.14

PNEUMOCYSTIS CARINII: DIAGNOSIS IN NON-INDUCED SPUTUM BY IMMUNOFLUORESCENCE

Weber,Günter*,Tschechne,B.**,Brunkhorst,U.**,Gerdelmann,R.*,
Schedel,I.**,Deicher,H.**,et al.**
*Publ.Hlth.Labs.,**Sch.Med.,Hannover, Fed.Rep.of Germany.

Objective. To develop a reliable routine procedure for diagnosing Pneumocystis (PC) in spontaneously expectorated sputum of patients with AIDS or suspected AIDS.
Methods. Non-commercial indirect immunofluorescence test (IFT) based on polyclonal rabbit-antiserum to PC.
Results. Non-induced sputa of 128 HIV-patients with suspected pneumocystosis (PCP) were examined. The IFT was diagnostic in 50 (39 %) patients. In 30 out of the 78 patients with a negative sputum diagnosis, a bronchoalveolar lavage (BAL) was performed subsequently, because PCP still was suspected.
In 3 of these cases PC was detected in the BAL material. Another sputum diagnosis was taken for false-positive due to the further clinical course. Thus, on the basis of clinical parameters and comparative sputum/BAL examination, 94 % sensitivity and 99 % specificity of the test was attained in this cluster of patients.
Conclusion. Our results suggest that PC is commonly present in spontaneously expectorated sputum of HIV-patients with PCP. A properly designed immunofluorescence technique makes this material a most useful diagnostic specimen.

T.B.P.15

PREDICTIVE DATA FOR POSITIVE BRONCHOALVEOLAR LAVAGE RESULTS IN PNEUMOCYSTIS PNEUMONIA.

Slim, Jihad*, DeLuca, A., Perez, G., Forrester, C., Johnson, E.S., Saint Michael's Medical Center, Newark, New Jersey, U.S.A.

Objective: To determine if any factors may be predictive of bronchoalveolar lavage (BAL) recovery of PCP in suspected cases of pneumonia.
Method: A retrospective review of 127 bronchoscopies performed for suspected PCP was undertaken with analysis of hospital charts. Symptoms, chemistry profile, arterial blood gases, chest x-rays and gallium scans were compared in 62 patients with positive and 65 with negative results for PCP.
Results: Those with positive results had an average shorter duration of anti PCP treatment prior to (BAL), had a lower incidence of negative chest x-rays, had 100% incidence of positive gallium scans and higher lactic dehydrogenase levels. Symptomatically those with positive (BAL) had longer duration of symptoms and lower incidence of productive cough. Arterial blood gas measurements, complete cell counts and T-cell studies showed no differences between groups.
Conclusion: There are some laboratory data (lactic dehydrogenase, chest x-ray and gallium scan) and/or symptoms (duration and productive cough) which can be predicti-   ositive (BAL) results.

T.B.P.16

UNUSUAL PATHOLOGIC MANIFESTATIONS OF PNEUMOCYSTIS CARINII PNEUMONIA (PCP) IN AIDS.

William D. Travis, S Pittaluga, GY Lipschik, FP Ognibene, AF Suffredini, HC Lane, et al.
National Institutes of Health, Bethesda, MD, USA

Objective: To investigate the pathologic features of PCP in AIDS patients.
Methods: 162 lung biopsies (156 transbronchial, 6 open biopsies) from 71 NIH AIDS patients with PCP were reviewed. Serial biopsies in 55 patients (2-9 total biopsies) and autopsies in 31 enabled study of the evolution of pathology of PCP.
Results: Several unusual pathologic manifestations of PCP were observed:

Histologic Feature	No. Biopsies (%)
Fibrosis	
Interstitial	74 (63)
Intraluminal	42 (36)
Absence of alveolar exudate	21 (18)
Numerous alveolar macrophages	8 (7)
Granulomatous inflammation	5 (4)
Marked chronic inflammation	4 (3)
Hyaline membranes	4 (3)
Bullous cystic changes	2 (2)
Minimal histologic reaction	2 (1)
Vascular infiltration and vasculitis	1 (1)

Conclusion: PCP has a wide spectrum of pathologic manifestations in AIDS patients. It is important to recognise unusual pathologic features of PCP since it is the most common life-threatening pulmonary complication of AIDS.

T.B.P.17

How predictive are LDH-elevations for the severity of pneumocystis carinii pneumonia in AIDS patients?

Elsing,C. , Erckenbrecht, J.F. , Worth,H. , Strohmeyer,G.
Department of Medicine, University of Düsseldorf, 4000 Düsseldorf Moorenstr.5 FRG.

The elevation of plasma lactate dehydrogenase (LDH) is a common phenomenon during pneumocystis carinii pneumonia in AIDS. Prospectively we evaluated the reliability of LDH eleavation to predict severe respiratory distress; arteriell oxygen pressure (PO2) less than 60 mmHg; during pneumocystis carinii pneumonia (PCP). We, therefore, correlated LDH and PO2 in 13 patients with 14 episodes of PCP. A significant negative correlation between both values were found (r=-0.46; p 0.001). For LDH values less than 300 U/l, only 3 of 52 PO2 values were less than 60 mmHg (specifity 96.2%). For LDH values higher than 300 U/l only 38.5% of the PO2 values were less than 60 mmHg (sensitivity 38.5%). When LDH values were between 300 and 600 U/l the range of PO2 values was between 32 and 94 mmHg. Positive and negative prediction values of LDH 300 U/l for the diagnosis of severe respiratory distress were 50% (18/36) and 81% (13/16), respectively.
Conclusion: LDH and PO2 are significantly correlate in pneumocystis carinii pneumonia. However, due to low sensitivity and low predictive value, LDH determination is of limited value in prediction of severe respiratory distress in pneumocystis carinii pneumonia in AIDS patients.

T.B.P.18

COMPARISON OF FIRST EPISODE OF PCP IN COMMUNITY PATIENTS AND INMATES

Sharp, Victoria, Andrews A, Heyman B, Weiss R
Albany Medical Center, Albany, New York, U.S.A.

Objective: Compare survival of community patients (CP) and inmates (I) diagnosed with their first episode of PCP.
Methods: Retrospective review of all patients with primary PCP admitted to the AMC AIDS Treatment Center between 1/1/87 and 10/31/88. Only those patients with documented PCP, ie confirmed by bronchoscopy, were included in the study. Ethnic origin, risk group, lab parameters on admission, use of AZT and survival were evaluated.
Results: 20 community patients and 26 inmates were included in the study. In the community patients, there were 80% Caucasion, 10% black, 10% Hispanic. Among inmates there were 12% Caucasion, 27% black, 61% Hispanic. Risk group data showed community patients 65% bi/homosexual, 20% IVDA, 15% other. Inmates had 77% IVDA, 8% bi/homosexual, 15% IVDA/Homosexual. 20% of community patients were on AZT prior to admission; 5% of inmate patients were on AZT prior to admission. Average LDH on admission: CP=348; I=408. Average Hct on admission: CP=37.5; I=33.4. Mortality was CP=5%; I=23%. Mortality in those individuals not on AZT: CP=6%; I=24%.
Conclusion: Inmates with primary PCP arrived at AMC sicker than community patients, as evidenced by higher LDH and lower Hct in the inmate population. Furthermore, despite presumably similar workup and treatment by the medical staff at ATC, inmates did worse than community patients as evidenced by their significantly higher mortality.

T.B.P.19

PNEUMOCYSTOSE ET SIDA A BRAZZAVILLE, CONGO.

Carme, Bernard, Mboussa J., Mpele, P., Datry, A. Mouanga-Yidika, G. Itoua-Ngaporo A. et al. Centre Hospitalier et Universitaire de Brazzaville, Congo. Centre Hospitalo-Universitaire Pitié-Salpêtrière, Paris, France.

Objectif: Confirmer la rareté de la pneumocystose chez les sujets congolais atteints de SIDA.

Methodes: 30 sujets (16 hommes et 14 femmes), agês de 23 à 51 ans atteints de SIDA (sérologie VIH positive et critères de la définition OMS, Bangui 1985), présentant des manifestations pulmonaires et ayant eu une recherche de BAAR négative, on fait l'objet, à Brazzaville, d'un lavage broncho-alvéolaire (LBA). Les étalements du culot de centrifugation du produit de lavage ont été colorés selon la technique d'imprégnation argentique rapide de MUSTO et coll. afin de rechercher Pneumocystis carinii. Résultats: Pour les patients investigués, le tableau clinique associait dans 75% des cas toux, dyspnée, douleurs thoraciques et fièvres. La radiographie du poumon retrouvait chez la moitié des patients une pneumopathie localisée uni ou bilatérale et dans 25% des cas une pneumopathie interstitielle. La notion de prise de sulfaméthoxazole et triméthoprime, dans les jours ayant précédés le LBA, se rencontrait une fois sur 4. Quatre cas seulement de pneumocystose ont été diagnostiqués (13.3%)
CONCLUSION: La rareté de la pneumocystose est confirmée chez les sidéens brazzavillois.

T.B.P.20

NON OBVIOUS AIDS :
Pneumocystis carinii Pneumonia in the Elderly
VINTI, Henri ; PESCE, A. ; Taillan, B. ; DUJARDIN, P. ; CASSUTO, J.P.
Université de Nice, FRANCE.

Pneumocystis carinii Pneumonia (PCP) is the most common opportunistic infection in patients with AIDS. Diagnosis is mostly considered in young patients with risk factors ; it is obviousless in the elderly.
During the past two years, we observed in our department seven cases of PCP in patients over the age of 60. Four of these patients were shown to have AIDS (one homosexual man and three who had had a blood transfusion en 1984). The fifth, a bisexual man, had been seropositive for HIV since 1986, and the remaining two had other imunosuppressive disease. In all cases, diagnosis was established on finding the pathogen in the liquid of broncho-alveolar lavage. Except in the patient who was already known to be seropositive for HIV, diagnosis was delayed, and bronchoscopy was performed only when the clinical and radiological finding showed deterioration despite conventional antimicrobial treatment.
In our region, 15 % of patients with AIDS are over 60, because of the high prevalence of the disease (129 cases per million inhabitants) and the mean age of the population (27 % over 60). We think that PCP should be systematically considered in elderly patients with atypical, unresponsive chest infection.

Traitement de la PCP : Pentamidien et autres médicaments (traitement clinique)
PCP Treatment: Pentamidine and Other Drugs (Clinical Treatment)

T.B.P.21

PRIMARY AND SECONDARY PROPHYLAXIS AGAINST PNEUMOCYSTIS CARINII PNEUMONIA WITH FANSIDAR®

Ruf, Bernhard, Pohle, H.D., Schürmann, D.
II. Department of Internal Medicine, Rudolf Virchow University Clinic (Wedding), Freie Universität Berlin, FRG.

Objective: Because of the high incidence of Pneumocystis carinii pneumonia (PcP) in HIV infected patients and because of the high incidence of relapses after therapy, specific prophylaxis is essential. The efficacy of Fansidar® in primary prophylaxis and Fansidar® vs. aerosolized pentamidine in secondary prophylaxis was evaluated.
Methods: Fansidar® dosage: 2 tablets twice a week, folinic acid substitution. Aerosolized pentamidine: 60 mg every two vs. 300 mg every four weeks. Patients who had Fansidar® prophylaxis after CNS toxoplasmosis without PcP manifestation before, were enrolled in the primary prophylaxis group. Secondary prophylaxis with Fansidar® was started within one week after the end of PcP therapy.
Results: Five of 47 patients (10 %) who had secondary Fansidar® prophylaxis developed relapses of PcP, but 7/22 patients (32 %) without prophylaxis. Thirteen patients are under aerosolized pentamidine prophylaxis; none of the patients developed PcP relapses. In 1/35 patients (3 %) under primary Fansidar® prophylaxis a PcP episode was seen, but in 3/14 Patienten (21 %) without primary prophylaxis. Side effects related to Fansidar® were noted in 21/82 patients, but only in 3 patients Fansidar® had to be discontinued.
Conclusion. Fansidar® is highly effective in prophylaxis against PcP, especially in primary prophylaxis. First results showed aerosolized pentamidine probably equally effective.

T.B.P.22

A QUANTITATIVE SCORING SYSTEM FOR EVALUATING THE RESPONSE TO THERAPY OF PNEUMOCYSTIC CARINII PNEUMONIA (PCP)

Nichols, Larry*, Black, J.**, Sattler, F.', & Feinberg,J.+
*Research Triangle Institute, Research Triangle Park, NC,USA, **Indiana University, Indianapolis, IN,USA, 'University of Southern California, CA, USA, +Natl. Inst. of Allergy & Infectious Diseases, Bethesda, MD, USA.

Objective: Develop an instrument for measuring response to PCP therapy.
Methods: A "pneumonia evaluation" score for the key signs and symptoms of PCP was devised, incorporating subscores for respiratory rate, fever, cough, chest tightness, dyspnea and supplemental oxygen requirement. It was compared to arterial-alveolar (A-a) gradients, chest x-rays and global clinical assessments in the first 30 evaluable cases of an ongoing NIAID-sponsored AIDS Clinical Trials Group study of PCP therapy. Thirty more cases will ripen and be analyzed in April, 1989.
Results: In cases with favorable outcomes at day 21, all showed improved scores (average 81%, range 35-100%) at day 21 and all except 1 showed improved scores (average 49%, range 6-90%) at day 10. In those with A-a gradients calculated on room air, all showed improvements (average 49%, range 19-100%) at day 21 and all except 1 showed improvements at day 10, (average 31%, range 3-61%). In the 6 cases with clinically unfavorable outcomes, many of the scores had little room to worsen: one improved 7% and the other 5 worsened an average of 24% (range 7-61%). The chest x-ray results tended to lag behind both the scores and the A-a gradients.
Conclusion: This scoring system may reflect response to PCP therapy more rapidly and with greater amplitude than A-a gradients or chest x-rays.
(This work was supported by the NIAID AIDS Clinical Trials Group program.)

T.B.P.23

AEROSOLIZED PENTAMIDINE (AP) IN THE TREATMENT OF PCP EPISODES : AN OPEN MULTINATIONAL TRIAL, PRELIMINARY RESULTS ON 70 PATIENTS.

GIRARD, PIERRE MARIE* - LECOMPTE, T, ** - LAZZARIN, A *** and the A.P WORKING GROUP *HOPITAL BICHAT, CLAUDE BERNARD ; **HOPITAL ST LOUIS, PARIS, FRANCE ; ***HOPITAL L. SACCO, MILANO ITALY.

METHODS -HIV positive patients were enrolled if they met the following criteria : histologically proven PCP, mild or moderate episode defined by PO2 > 55 mmhg ; patients previously treated for the present episode were enrolled only if they had failed to respond to previous drugs. AP was administered at the dose of 300 mg once a day with a jet nebuliser (RESPIGARD II). It was intended to treat the patients a minimum of 7 days and a maximum 21 days ; patients were assessed clinically daily and 4 weeks after AP discontinuation ; ABG, lung X ray and lab values were repeated every 3rd day. A favorable response was defined by normal ABG, apyrexia, no dyspnea, and an improvement of the lung X ray at the end of therapy with no relapse after AP discontinuation.
RESULTS - Up to now among 120 patients planned, 70 males patients (mean age of 34.5 years) were enrolled, 63 of whom being considered as suitable for efficacy analysis.
43/63 patients suffered from their first bout of PCP ; 6/63 patients had failed to prior therapy ; the mean PO2 was 76.9 mmhg. Overall 68 % of the patients responded to AP and 32 % failed (one patient died) ; in the patients who responded to AP, dyspnea apyrexia and improvement were obtained with a mean of 7.5 and 8.9 days respectively ; patients with no pretherapy alveolar damage (on lung X ray) showed a higher cure rate than patients with alveolar damages (77 % VS 52,2 % p = 0.05). All clinical failures but 2 responded to Cotrimoxazole. Mild cough or bronchospasm occured in 25 % of the patients and the systemic tolerance was excellent.
CONCLUSION - The overall response rate was somewhat lower and the onset of improvement was slower than with cotrimoxazole or parenteral pentamidine. Because the tolerance was good, another clinical trial has been initiated to evaluate a 600 mg AP daily dosage.

T.B.P.24

SURVIVAL RATE AND PROGNOSIS FOR AIDS PATIENTS WITH SEVERE PNEUMOCYSTIS CARINI PNEUMONIA (PCP). REQUIRING MECHANICALLY VENTILATION (MV).

Nielsen, Thyge L.*, Guldager H.**, Pedersen C.*, Mathiesen L.*, Nielsen J.O.*
*Dept. of Infect. Dis.**Dept. of Intensive Care, University Hospital of Hvidovre, Copenhagen, Denmark.

Objective. To evaluate the prognosis for AIDS patients with severe PCP requiring MV.
Methods. Clinical outcome was evaluated in 19 consecutive patients (all men 17 homosexuals, 2 with unknown riskfactor) with first episode of PCP who required MV. Survivors were defined as patients discharged from hospital.
Results. lo patients (53%) survived. 2 (lo%) of the survivors died, 286 (Kaposi) and 4ol days (Bovine TB) after MV respectilleły. 8 (42%) patients are alive after mean 475+/- 22o days and 5 (26%) patients returned to their normal civil jobs. The mean time in hospital, before specific therapy was initiated, was 2.3 +/- 1.7 days for survivors compared to 8.o +/- 7.7 days for nonsurvivors (p=o.o3) and the mean duration of MV 5.4 +/- 2.4 for survivors compared to lo.8 +/- 5.7 days for nonsurvivors (p=o.o2).
There was no significant differences with respect to: 1. duration of symptoms before admission. 2. use of corticosteroids. 3. addition of secondary diagnosis or 4. respiratory status immediately after intubation.
Conclusion. The survival rate for first episode of PCP requiring MV are better than previously reported. The prognosis for survivors are equal to the prognosis for other AIDS patients. Early diagnosis and treatment seem to be important for the survival. The usefullness of corticosteroids still remains to be proved.

T.B.P.25

REDUCED DOSE OR AEROSOLIZED PENTAMIDINE TREATMENT FOR *PNEUMOCYSTIS CARINII* PNEUMONIA (PCP): 3-6 MONTH FOLLOW-UP

John E. Conte, Jr., D Chernoff, H Hollander, D Feigal, J Golden, Department of Medicine, University of California, San Francisco, San Francisco, California.

Objective: To investigate the toxicity, efficacy, and pharmacokinetics of reduced dose or aerosolized pentamidine for the treatment of mild PCP. Methods: 45 patients were entered into a randomized trial of reduced dose (3 mg/kg/day) intravenous pentamidine or aerosolized pentamidine (600 mg/day; Respirgard-2 nebulizer) for mild PCP ($PO2 \geq 60$ mm Hg). Pentamidine concentrations in plasma and bronchoalveolar lavage (BAL) were measured by HPLC. Results: Of 22 IV patients, 1 was excluded because PCP was not confirmed, 4 failed to respond to therapy, 2 developed major toxicity and 17/21 (81.0%) responded satisfactorily. Of 23 aerosolized patients, PCP was not confirmed in 1, 1 received no drug, 4 failed to respond, none developed major toxicity, and 17/19 (89.4%) responded satisfactorily. There were 2 deaths in the aerosolized group. The early relapse rate (3 months) were 0/17 and 10/15 ($p<.05$) for IV or aerosolized therapy.

Bronchoalveolar lavage concentrations of pentamidine were 89.8 ± 48.4 ng/ml and 110 ± 90.2 ng/ml ($p>0.05$; NS) in patients with or without relapse. Conclusion: Mild PCP responds satisfactorily to reduced dose IV or aerosolized pentamidine. The early relapse rate following aerosolized treatment is high and was not prevented by aerosolized pentamidine prophylaxis. BAL concentrations of pentamidine were not correlated with relapse. Pentamidine accumulates in plasma with daily intravenous therapy even in patients with normal renal function.

T.B.P.26

PENETRATION OF TRIMETHOPRIM(TMP) COMPARED WITH THAT OF SULFAMETHOXAZOLE(SMX) IN BRONCHOALVEOLAR LAVAGE FLUID (BALF) DURING PNEUMOCYSTIS CARINII PNEUMONIA (PCP).

Decazes, Jean-Marie*; Durand, S.*; Kitzis, M.D.**; Mohler, J.***; Hirsch, A.*.
Hospital Saint-Louis*, Saint-Joseph** and Bichat***, Paris, France.

Aim. To improve knowledge on local kinetics of high doses TMP/SMX by comparing penetration of TMP and SMX into the extracelluler fraction of alveolar exsudate where PC is present.
Methods. 10 HIV+ patients with suspected (and later confirmed) PCP received a constant infusion of TMP (20mg/kg/d)-SMX (100mg/kg/d), initiated 2h before BAL. BAL was performed in the right middle lobe. Blood and BALF samples obtained during BAL were centrifuged and stored at -80°. TMP and SMX were assayed by bioassay and HPLC, respectively.

Results	Serum (µg/ml)	BALF (µg/ml)	Pp (%)	[TMP] BALF/[TMP] serum [SMX] BALF/[SMX] serum
TMP	3.1 ± 1.3	1.9 ± 0.7	76 ± 36	57 ± 40
SMX	162 ± 12	3.0 ± 1.4	1.8 ± 1.2	

Discussion. Although BAL dilution may differ, it is clearly equal for both drugs in one individual patient. Thus, comparing BALF/serum ratios may be a way to compare aptitudes of compounds given simultaneously to penetrate into the extracelluler fraction of alveolar fluid.
Conclusion. In patients with PCP, TMP exhibits a markedly superior aptitude to penetrate into the extracelluler fraction of alveolar fluid as compared to SMX. Consequently a ≈1/1 ratio is present at the site of infection. This study suggests that TMP-SMX dosage ratios different from that commercially available may deserve studies in experimental models of PCP.

T.B.P.27

TRAITEMENT DE LA PNEUMOCYSTOSE DU SIDA PAR LE DFMO

Girard, Pierre-Marie*+ ; Garou, A.* ; Rozenbaum, W.* ; Perronne, C.* ; Wolff, M.* ; Coulaud, JP.*
*Hôpital Bichat - Claude Bernard, +INSERM U13, 75019 Paris, France.

Objectif. Evaluation de l'efficacité et de la tolérance du Difluorométhylornithine (DFMO) dans la pneumocystose au cours du SIDA.
Patients et méthodes. Le DFMO a été administré à la dose de 400 mg/kg/j IV pendant 15 jours puis 300 mg/kg/j P.O. pendant 30 jours. L'efficacité a pu être évaluée chez 22 patients : Groupe I (n=5) PaO_2 = 49 mmHg (27-68) : traitement de première intention, Groupe II (n=17) PaO2 = 63 mmHg (38-92) : traitement de relais après intolérance (n=11) ou échec d'un autre traitement (n=6). La tolérance a été évaluée chez 27 patients.
Résultats. La durée moyenne du traitement a été de 20 jours (4-57). Groupe I : 3/5 guérison ou améliorations. Groupe II : 15/17 (88 %) guérisons ou améliorations. 91 % de réponses favorables ont été obtenues chez les 11 patients dont la PaO_2 était supérieure à 50 mmHg versus 72 % chez les 11 patients avec PaO_2 inférieure à 50 mmHg. Les effets secondaires les plus fréquents étaient : thrombopénie (52 %), anémie (41 %), neutropénie (37 %), diarrhée (30 %). Ils ont nécessité l'arrêt du DFMO dans 9/27 cas (33 %).
Conclusion. 1) En traitement de première intention, l'efficacité du DFMO semble inférieure à celle des traitements conventionnels. 2) En relais, le taux global de réponse favorable (88 %) est élevé mais pourrait être lié à l'effet du traitement antérieur. 3) La toxicité hématologique est fréquente.

T.B.P.28

AEROSOL THERAPY WITH PENTAMIDINE ISETHIONATE IN ACUTE MODERATE CASES OF PNEUMOCYSTIS CARINII PNEUMONIA (PCP)

Arastéh, Keikawus, Schneider,Ch., Nehm,K., Schaefer,U., Heise,W., L'age,M.
Auguste-Viktoria-Hospital, FRG, Rubensstrasse 125, 1 000 Berlin 41

Objektive. To examine the effectiveness, side effects and pharmacokinetik data of aerosol therapy with Pentamidine.
Methods. Because of toxic side effects, Pentamidine isethionate by parenteral application can only be considered as a second choice in the therapy of PCP. In an open prospective multi-centered study in 1988, ten patients with light to moderate cases of PCP were treated with aerosol therapy. The most important criteria for inclusion in this study were PaO2 over 60 mmHg and expiratory volume over 2 liters or 50 % of the normal range. The histological diagnosis was supported by bronchoskopy. The patients received 300 mg of Pentamidine daily by inhalation (Respigard II) over a period of 21 days. Additionaly, the Pentamidine level in the blood and in 24 hour-urine samples were measured by a modified HPLC method. Controlled factors were blood count, blood sugar, lactic acid, and the laboratory levels of the liver and kidney functions.
Conclusion. For light to moderate cases of PCP, aerosol therapy with Pentamidine administered by the proper inhalation systems present an alternative to the formaly known methods. However, a 300 mg dosage appears too low. Further research is needed to determine the optimal dosage.
Results. Eight out of ten patients were successfully treated, although complications were created by accompanying infections and intrapulmonary Kaposi-Sarkoma. The measured Pentamidine level in the blood stayed in a range from 0-10 ng/ml. The secretion in the urine was found to be 00.1 - 0.5 o/oo of the inhaled dosage. A cumulative effect did not occur. Contrary to the above mentioned method of parenteral application, no toxic side effects were found.
Of the remaining two patients, one had an early relapse. The other had to be transferred to another form of therapy due to a worsened X-ray.

T.B.P.29

Eflornithine in the treatment of Pneumocystis Carinii Pneumonia (PCP).

Neibart, E.P., Dembitzer, F., Hammer, G.S., Dembitzer, R., Sacks,H.S., Hirschman, S.Z., Mt Sinai Hospital, New York.

Eflornithine (E) has been demonstrated to have activity against PCP. From 1985 to 1988 42 patients that had failed or had had significant adverse reactions to Pentamidine and TMP-SMX were treated with E. There were 23 definite responses (R) and 2 propable responses. One patient died of another opportunistic infection and 16 patient failed therapy (F). No differences were observed between responders and failures in the duration of AIDS, number of previous episodes of PCP,presence of other opportunistic infections or KS. Onlv 1 responder required mechanical ventilation at the start of therapy as opposed to 12/16 failures ($p<.001$). The initial WBC was 5.09 ∓ 1.88 in R as compared to 9.18 ∓ 4.26 in F ($p<.01$). There was a trend to higher A-a gradient in F (mean 80 ∓ 19) vs R (72 + 16) but this was not satistically different ($p>.2$). Adverse effects included thrombocytopenia, in 74% of patients, the WBC declined in 65% and hematocrit in 16%. No patient had significant bleeding or a secondary infection. Four patients had diarrhea requiring antimotility agents. E is effective therapy in patients with mild to moderate disease. As with standard therapy outcome is poor in patients with severe disease requiring mechanical ventilation. Further dose-response investigation to maximize efficacy and minimize toxicity is indicated.

T.B.P.30

CLINDAMYCIN PLUS PRIMAQUINE AS PRIMARY THERAPY FOR PNEUMOCYSTIS CARINII (PC) PNEUMONIA IN AIDS PATIENTS

Black, John R.[1]; Feinberg, J.[2]; Fass, R.J.[3]; Plouffe, J.F.[3]; Murphy, R.[4]; Leoung, G.[5]; et al. [1]Indiana University, Indianapolis, IN, [2]NIAID AIDS Treatment Branch, Bethesda, MD, [3]Ohio State University, Columbus OH, [4]Northwestern University, Chicago, IL, [5]San Francisco General Hospital, San Francisco, CA, USA.

Objective. An open-labelled, pilot study to determine safety and efficacy of clindamycin and primaquine for treatment of mild (A - a gradient < 30 mm/Hg) PC pneumonia in AIDS patients. Methods. Histologically proven PC pneumonia was required for entry. Patients were excluded if they had received prior antiprotozoal therapy or prophylaxis within 6 weeks prior to entry, or if they had significant diarrhea, absolute granulocyte count (AGC) < 1000/mm^3, platelet count < 100,000/mm^3, Hgb < 10 gm, creatinine > 2mg/dl, or SGOT > 5 times normal. Clindamycin 900 mg IV every 8 hours plus primaquine 30 mg orally per day were administered for the first 10 days. Clindamycin dosing was then changed to 450 mg orally every 6 hours if patients met defined criteria for clinical response. Total duration of treatment was 21 days. Outcome was determined by a pneumonia scoring system incorporating fever, respiratory rate, dyspnea, cough, chest tightness, supplemental oxygen requirement and chest X-ray, and by change in A - a gradient. Bimonthly aerosol pentamidine prophylaxis was begun 2 wks after completing therapy. Results. All 8 patients entered to date showed marked improvement by the 7th day of treatment. Six patients completed treatment with clindamycin and primaquine and were cured. Two patients experienced side effects mandating change to standard therapy during the second week; one developed fever and rash, the other transient, severe neutropenia (AGC of 300). Both were cured. Additional minor side effects included rash, mild neutropenia, and mild methemoglobinemia. No relapses have yet occurred (mean follow-up after treatment: 8 weeks; range: 1-21 weeks). An additional 3 patients were treated in San Francisco with a totally oral clindamycin and primaquine regimen. All improved clinically but failed to complete 21 days of treatment due to rash (2) or mild transaminase elevation (1).
Conclusions. Although further study is warranted, clindamycin and primaquine may represent an alternative treatment for PC pneumonia in AIDS.

T.B.P.31 CORRELATION BETWEEN ICU SURVIVAL AND REQUIRED CPAP/PEEP IN AIDS PATIENTS WITH PNEUMOCYSTIS CARINII PNEUMONIA

Skoutelis, Athanasios; Peruzzi, W; Currie, D; Murphy, R; Cane, R and Shapiro, B.
Northwestern University, Chicago, Il, USA.

Objective: The survival of patients (pts) with Pneumocystis carinii pneumonia (PCP) and AIDS who require ICU admission and mechanical ventilation has been shown to be poor. This study was undertaken to determine the survival rates of pts with PCP treated with positive airway pressure (CPAP by mask, CPAP by endotracheal tube, PEEP with mechanical ventilatory support).
Methods: The charts of all pts with PCP admitted to the ICU between 1985 and 1989 were reviewed retrospectively to determine patterns of survival and correlation between survival and treatment with CPAP/PEEP. The pts were treated by the same physician group using established protocols for airway pressure therapy to maintain adequate oxygenation.
Results: Preliminary data from 24 pts requiring CPAP/PEEP revealed that 6/24 (25%) were discharged from the ICU alive, and were ultimately discharged from the hospital. The highest CPAP/PEEP level needed to maintain adequate oxygenation was a mean of 10 ± 3.5 cm H20 in survivors and 15 ± 4.5 cm H20 in non-survivors. These differences are highly significant at $p < 0.001$ by chi square analysis.
Conclusion: We routinely use CPAP/PEEP to improve oxygenation in pts with PCP. The need for CPAP/PEEP levels of 15 cm H20 or greater to maintain acceptable oxygenation is associated with a significantly higher mortality in these pts. This is most likely related to a greater degree of lung involvement with pneumocystis in those requiring higher CPAP/PEEP levels.

T.B.P.33 PROSPECTIVE RANDOMIZED STUDY OF TMP/SMX (T/S) VERSUS PENTAMIDINE AEROSOL (P IN PNEUMOCYSTIS CARINII PNEUMONIA (PCP)

Dellamonica, Pierre* ; Durant J.*; Roger P.M.* ; Bernard E.* ; Mondain V.*; Lefichoux Y.*
* University Hospital, Nice, France.

In an open randomized study, 30 AIDS patients suffering from PCP whose arterial PO2 were higher than 60 mmHg were treated for 21 days with either T/S at 20/100 mg/kg/d (n = 15), or aerosol methanesulfonate Pentamidine (600 mg/d) administered daily during 30 minutes with an ultrasonic nebulizer system (n = 15). Patients were comparable in : age (38,6 v 38,5), first PCP episodes, arterial PO2 (71,6 v 71,5), and clinical and biological severity.
Results :

Number of patients	S/T 15	P 15	P Value
Treatment success	7	9	NS
Failures	1 (dead)	5 (dead = 2)	p = 0,06
Therapy modification (adverse reaction)	2	0	NS
Treatment success without modification but (minor adverse reaction)	5	0	p = 0,02
Not evaluable dead within 48 h	0	1	

NS = not significant
Conclusions : in our study a higher number of failures in the P group occured (p = 0,06), but no adverse systemic reactions (p = 0,02). Number of cured patients without treatment modification is not statitically different for the 2 groups. Patients in S/T group experienced more adverse reactions (p = 0,02).

T.B.P.35 THE USE OF STEROIDS IN THE THERAPY OF RESPIRATORY FAILURE COMPLICATING PNEUMOCYSTIS (PCP)

Schiff MJ; Farber HW; Kaplan MS. North Shore University Hospital & Cornell University Medical College, Manhasset, N.Y., U.S.A.

Objective. We studied the effect of adjuvant high dose corticosteroids in the treatment of 16 patients with AIDS and PCP resulting in respiratory failure.
Methods. Retrospective chart review of 16 patients with a PO2<60 on FIO2 ≥ 0.60 and/or PO2<50 on RA.
Results. Steroids was given in a dose of 20-40 mg Methylprednisilone intravenously q6h for 7-10 days. 13 men and 3 women, ages 20-65 were studied. Risk factors included homosexual (6), IV drug abusers (6) and 4 unknown. 4/16 were previously treated with Zidovudine at the time of admission. In 15/16 respiratory failure complicated the first episode of PCP. In 13/16 mechanical ventilation was required. 6/16 patients died without a response to steroids following respiratory failure. 5 recovered and were alive and discharged at 3 month follow-up. 4 appeared to recover initially but died within 1 month, and 1 initially responded but remains unconscious in the hospital. Of the 10 patients who appeared to respond initially to steroids, 8 had a relapse of PCP after stopping steroids. Relapse was defined as worsening chest x-ray and PO2 after an initial improvement. These were retreated for PCP.
Conclusion. Adjuvant steroid initially helped reverse respiratory failure due to PCP in 60% However, the relapse rate was high and only 31% remained alive 3 or more months later.

T.B.P.32 TREATMENT AND OUTCOME OF PNEUMOCYSTIS CARINII PNEUMONIA IN AIDS PATIENTS.

Lundgren, Jens D.; Pedersen, C.; Nielsen, T. Department of Infectious Diseases, Hvidovre University Hospital, Denmark.

Objective. To evaluate the efficacy and safety of treating Pneumocystis carinii pneumonia (PCP) in AIDS patients.
Methods. Analysis of a standardized protocol from 75 consecutive HIV positive patients diagnosed of having PCP admitted to our department.
Results. Eighty nine episodes of PCP were recorded, 83% by histologic verification and 17% by clinical criteria. Chest x-ray of 13 (15%) patients taken initial in the episode were normal. Patients were treated with sulfamethoxazole/trimethoprim (ST) (82 episodes, median daily dose of S/T : 4900/980 mg, median duration 20 days) and/or pentamidine (P) (17 episodes, median daily dose 200 mg, median duration 11 days). Two episodes of PCP were not treated. The ST and P regimens resulted both in about 50% objective side effects, but only 10% treated with ST and 24% treated with P had their treatment discontinued because of side effects. Of patients with primary PCP 7 (10%) patients died of PCP inspite of drug therapy. Twelve (16%) primary PCP patients and 5 (36%) patients with recurrent episodes of PCP died during hospitalization. No patient who died had a normal chest x-ray. Relapse of PCP after secondary prophylaxis with low dose ST (daily dose of S/T : 800/160 mg, average followup time 261 days) occurs in 3 (6%), compared to 11 (69%) patients who did not receive prophylaxis (average followup time 131 days) (p<0.00001). The survival rate after 1 year among patients with primary PCP with the diagnosis made in 1986 (23 patients) and 1987 (39 patients) was 0.52 and 0.74, respectively, as opposed to 0.08 when diagnosed prior to 1986 (13 patients) (p<0.01). Seven (64%) of 11 patients requiring mechanical ventilation were discharged from the hospital.
Conclusions. In most of our PCP patients, treatment with ST and P and secondary prophylaxis with ST is safe and effective. Controlled studies are needed to verify that newer alternatives are superior to treatment with ST and P. Furthermore, early diagnosis of PCP may improve the prognosis. Lastly, mechanical ventilation is a reasonable option when needed in patients with PCP.

T.B.P.34 THE BIOAVAILABILITY OF CO-TRIMOXAZOLE IN PATIENTS WITH AIDS RECEIVING TREATMENT FOR PNEUMOCYSTIS CARINII PNEUMONIA.

Wells, Carole*; Kapembwa, M.*; White, L.**; Cairns, C† and Wansbrough-Jones, M.*. *St George's Hospital, London, U.K.
**Southmead Hospital, Bristol, U.K.

Objective. To investigate the bioavailability of co-trimoxazole in AIDS patients with normal and abnormal fat absorption.
Methods. Five HIV antibody positive males mean age 38 years (20-60years), mean weight 60kg (48-70kg) receiving a mean dose of 124mg/kg/day co-trimoxazole for the treatment of P. carinii pneumonia were studied. Plasma concentration time profiles for trimethoprim (TMP) and sulphamethoxazole (SMX) were obtained during a 6 hour dosage interval after the same dose of co-trimoxazole given intravenously and orally. Serum levels of TMP and SMX were measured using high performance liquid chromatography. Fat absorption was determined by the measurement of $^{14}CO_2$ in breath following ingestion of a test meal containing ^{14}C triolein with 60g fat. Bioavailability was calculated using standard pharmacokinetic methods.
Results. The mean bioavailabilities of TMP and SMX in patients with fat malabsorption were 108 (±12SD)% and 91 (±11SD)% respectively. By comparison the mean bioavailabilities of TMP and SMX in patients with normal fat absorption were 90 (±4SD)% and 101 (±7SD)% respectively.
Conclusion. Preliminary data suggest that in patients with AIDS oral and intravenous co-trimoxazole achieve similar serum TMP and SMX levels even in the presence of abnormalities of fat absorption.

T.B.P.36 DIAGNOSIS AND TRATMENT OF PNEUMOCYSTIS PNEUMONIA: A SURVEY OF OREGON AND VANCOUVER, WASHINGTON PHYSICIANS

SAMPSON, JAMES M. *, SPENCE, CAROLE JANE *
*GOOD SAMARITAN HOSPITAL AND MEDICAL CENTER, PORTLAND, OREGON, USA.

OBJECTIVE: To describe how physicians in the state of Oregon and Vancouver, washington responded to questions about the diagnosis and treatment of pneumocystis pneumonia.
METHODS: Physicians were surveyed in the Portland area(including Vancouver) and the state of Oregon who were primary providers of care to those with AIDS. Physicians were offerred $20.00 payment for their time in filling out the survey. Forty five surveys were sent out with a three week return.
RESULTS: Thirty four surveys were returned with a 76% response rate. The following were the results found. The top lab results utilized at the initial evaluation were CBC and ABGS. Induced sputums and bronchoscopic BAL were the primary methods used in the diagnostic workup. The noninvasive test marker used in diagnosis was the abnormal chest X-Ray. When requested about the initial therapy prior to diagnosis, 29% used TMP/SMZ (IV) with varying dosages, 25% used oral TMP/SMZ and 23% used Pentamadine (IV). The second agent of choice after failure or toxicity, was IV Pentamadine by 53% and Inhaled Pentamadineby 15% of the respondents. Physicians favored Inhaled Pentamadine at 48% for maintenance therapy, with 26% using TMP/SMZ. Only 29% of the respondents did prophylactic treatment. Universal criteria for prophylactic treatment was CD T4 <200. Overall the physicians had seen approximately 642 patients with the majority seeing 10-20pts.
CONCLUSION: We will use the data to educate involved physicians in treatment.

T.B.P.37 PROSPECTIVE RANDOMIZED TREATMENT FOR PNEUMOCYSTIS CARINII-PNEUMONIA (PCP) IN AIDS PATIENTS.

Klein, N.C; Duncanson, Frederick P.; Lenox, T.H.; Kaswoff, O.; Pitta-Alvarez, A.; Wormser, G.P.; et al. New York Medical College, Valhalla, New York., U.S.A.

Despite the high incidence of PCP in HIV infection, few large scale prospective treatment trials have been reported. Objective: To compare trimethoprim-sulfamethoxazole (TS) (20 mg T & 100 mg S/kg/day) vs pentamidine isethionate (P) (4 mg/kg/day) both given IV for 21 days. Methods: One hundred sixty patients were randomized; ninety-two patients received TS and 68 P. Results: There were no significant differences in mean age (TS=36.8 P=36.3), % male (TS=80 P=81), risk factors (% IVDA TS=69 P=63; % homosexual/bisexual men TS=18 P=22; % other TS=13 P=15), % first episode of PCP (TS=91 P=88), mean temperatures (°F) (TS=102.2 P=102.0), mean A-a O_2 gradient TS=48 ± 17 P=44 ± 20) and mean lymphocyte count (TS=1090 P=1133). On or after day 5, patients were evaluated for response to therapy. Failure to complete therapy on initial drug was common 74 (80%) for TS and 47 (69%) for P (NS). Of those receiving TS, 4 died within 5 days, (42%) required change in therapy for failure to respond, and 31 (34%) required change for severe toxicity (neutropenia 15, rash 11, hepatitis 4, nausea and vomiting 4, renal insufficiency 1). Of those receiving P, 3 died within 5 days, 27 (40%) required change in therapy for failure to respond, and 17 (25%) required change for severe toxicity (hypoglycemia 5, neutropenia 4, hypotension 4, rash 3, renal insufficiency 3, fever 1). The overall survival was similar in the TS (67%) vs P (74%) groups. The survival rates for those requiring change in therapy were: TS followed by P (TS-P) due to failure 46%, TS-P due to toxicity 97%; P followed by TS (P-TS) due to failure 56%, P-TS due to toxicity 94%. Survical rates (at end of therapy) for groups not requiring change and completing 5 days of therapy were TS (83%) and P (79%) (NS). Conclusion: TS and P are equivalent therapy for PCP in AIDS patients. Neither can be relied on solely in the treatment of this pneumonia. Change in therapy due to drug toxicity is not associated with a worsened survival rate (96%) in contrast to change due to failure to respond (50%) ($p < .01$)

T.B.P.38 PENTAMIDINE USE IN A TERTIARY CARE HOSPITAL 1984-1988

Miedzinski, L.J.; Taylor, G.D. and Nazarali, S.
University of Alberta, Edmonton, Canada.

Objective: To review use of Pentamidine at a tertiary care centre in Northern Alberta, since first reported case of AIDS in 1983 and first cardiac transplant in 1985.
Method: Patient chart review of pharmacy list.
Results: Increasing use of pentamidine was noted annually from 1984 (1 course) through 1988 (23 courses). A total of 31 patients (27 male, 4 female) received 36 courses of treatment ranging from 2 to 30 days. Most patients had an underlying disorder of AIDS (22), but 7 patient had other predisposing factors to Pneumocystis carinii pneumonia (PCP) including 4 patients with cardiac transplants. The diagnosis of PCP was confirmed on 23 occasions. Fifteen courses of pentamidine were started after inital cotrimoxazole had produced side effects while 8 were started for failure to improve on cotrimoxazole.
On 12 occasions pentamidine was discontinued because of well recognized side effects. In 1 case, hypoglycemia persisted 2 weeks following discontinuation of the drug. In 50% of the cardiac transplant recipients, other drug level management was complicated by pentamidine.
Conclusion: Use of the unlicensed drug pentamidine has increased at our centre with increasing numbers of HIV infected patients and transplantation recipients. A significant number of cases (13%) occurred in cardiac transplant recipients where drug management was made more difficult.

T.B.P.39 ERYTHROMYCIN IN THE TREATMENT OF PcP IN AIDS PATIENTS

Dörlemann, Alois; Reisinger, E.; Schwander, S.; Meyer, A. and Dietrich M.
Clinical Dept., Institute for Tropical Medicine, Hamburg, Fed. Rep. of Germany.

Objective. We studied retrospectively 17 episodes of PcP in 14 patients diagnosed between April 1985 and October 1988 which were treated by erythromycin. The patients had a known or an acutely appearing allergic/toxic reaction to the standard therapy by TMP/SMX and/or parenteral pentamidine.
Methods. In 11 out of 17 episodes, the diagnosis of PcP was histologically proven. All of the 17 episodes were characterized by PcP-typical clinical picture, the typical x-ray changes of the lungs, and elevation of ESR, LDH, neopterin and serum immunoglobulins. All patients had a marked cellular immunodeficiency. The erythromycin regimen was 4-6x 500 mg daily. The mean duration of therapy was 23 days. Severe side effects were not seen. In 5 cases, erythromycin was administered immediately after diagnosis.The other 12 episodes had been pretreated by TMP/SMX and/or parenteral pentamidine. The mean duration of pretreatment with TMP/SMX was 10 days, with pentamidine 7 days.
Results. In 15 of 17 episodes of PcP, erythromycin treatment was successful and achieved complete cure. In 2 cases of PcP proven by bronchoscopy and histology and pretreated by TMP/SMX, the symptoms did not improve under a 7-day treatment with erythromycin. These patients received pentamidine i.v. which resulted in cure. The follow-up showed that after 7 episodes treated successfully with erythromycin, relapse occurred after a mean of 7.2 months. Eight of the 14 patients died after a mean of 5.2 months because of other opportunistic infections or kachexia without a relapse of PcP.
Conclusion. Erythromycin is effective in the treatment of PcP. Prospective comparative studies are desirable.

T.B.P.40 TREATMENT OF AIDS-RELATED PCP BY PENTAMIDINE INHALATION

Meyer, Andreas; Dietrich, M. for the German Multicenter Study Group
Inst. f. Tropical Medicine, Clin. Dept., Hamburg, Fed. Rep. of Germany.

Objective. To evaluate the safety and efficacy of aerosol pentamidine isethionate.
Methods. 28 patients with mild or moderate PcP ($PO_2 \geq 55$ mm Hg) were treated by inhalation of pentamidine, 300 mg once daily for 21 days using a Respigard II nebulizer. Successful treatment was defined as substantial improvement after the first week of treatment and an untreated relapse-free period of at least 4 weeks' follow-up.
Results.

Successful treatment	Early failure within the first days	Failure	Chest x-ray not completely cleared	Early relapse (within 4 weeks)
17 (61%)	4	5	1	1

Initial PO_2 in patients with successful treatment ranged from 56-126 (median 78 mm Hg). In the group of treatment failure (n=11) the initial PO_2 ranged from 55-98 (median 66 mm Hg). This difference was not significant (Wilcoxon's Test, $p > 0.1$). Major side effects could not be observed. Continuously taken blood samples showed serum levels of pentamidine ranging from 0-10 ng/ml, whereas i.v. administration leads to serum levels of about 400 ng/ml. However, half of the patients developed cough during the first days of inhalation. This could be prevented by the previous administration of terbutaline. Some patients had a bitter taste which disappeared within minutes after inhalation, in some cases loss of appetite occurred. One case of mild erythroderma responded to antihistaminic treatment.
Conclusion. The efficacy of aerosol pentamidine is comparable to standard therapy by cotrimoxazole or pentamidine (i.v., i.m.). Acceptance by the patients was satisfactory. No severe adverse reaction occurred.

T.B.P.41 TRAITEMENT DE LA PNEUMOCYSTOSE PAR LE COTRIMOXAZOLE

TRAORE Bougary; ECKERT D.; ROSENHEIM M.; GENTILINI M.
Département de Médecine Tropicale,Santé Publique et Parasitologie
Université de Paris VII.France.

Objectif. Analyser l'efficacité et la tolérance du cotrimoxazole dans le traitement de la pneumocystose.
Méthodes.Etude retrospective portant sur des patients atteints de pneumocystose entre 1985 et 1988. Les résultats sont exprimés en m±ds; les comparaisons sont faites à l'aide du test apparié de Student.
Résultats. 100 sujets, moyenne d'âge=36±9 ans. 76 étaient homosexuels, 10 toxicomanes intraveineux, 4 polytransfusés et 13 autres. Le traitement était efficace pour 86 patients,inefficace pour 4 patients, parmi lesquels 3 présentaient une infection pulmonaire associée. 10 sujets avaient arrêté le traitement pour raison d'effets secondaires.

Paramètres biologiques	N° patients	Période du traitement J0	J20	p
P.neutro	66	4215±2462	2262±2107	<0.0001
P.éosino	58	83±99	129±132	<0.002
Hémoglob.	70	11.33±2.08	10.47±1.70	<0.0001
SGOT	47	49±69	68±99	<0.02
SGPT	47	43±41	90±116	<0.004

Conclusion Le cotrimoxazole est efficace dans le traitement de la pneumocystose,mais des effets myélotoxiques demeurent.

T.B.P.42 PNEUMOCYSTIS CARINII PNEUMONIA IN THE ACQUIRED IMMUNE DEFICIENCY SYNDROME (AIDS)

David Haase*, W.Ghesquiere*, L.Johnston*, W.Schlech*, T.Marrie*, J.Whalen**. Depts. of Medicine* and Radiology**, Victoria General Hospital, Halifax, N.S., Canada.

Objective. Analysis of Pneumocystis carinii pneumonia (PCP) in patients with AIDS. Methods. Retrospective chart and CXR review. Results. Since 1983 we have treated 31 patients with AIDS and PCP. All except 5 were homosexual males, with 22 (71%) having PCP as the initial manifestation of AIDS. All patients had CXR changes on presentation. Three had atypical changes including lobar consolidation and multiple cavities. Arterial pO_2 on room air ranged from 33-87 (av61). Diagnosis was made in 32 of 39 episodes (82%) using bronchoalveolar lavage. Therapy was initiated with trimethoprim-sulpha (T-S) or pentamidine (P). Nine of 27 episodes (33%) were successfully treated with T-S alone vs 3 of 11 (27%) with P alone. Eleven of 21 (52%) experienced adverse effects with T-S vs 8 of 11 (73%) to P. Adjunctive steroid therapy was required in 16 of 39 episodes (41%) with 9 deaths subsequently. Overall 11 of 39 episodes (28%) resulted in death, 7 in association with concomitant CMV infection. Ten of 31 patients (32%) had two or more episodes of PCP occurring within 5-27 (av11.4) mo. of successful therapy.
Conclusion. Our experience parallels that reported from other centres in N.America.

T.B.P.43

HIGH RATES OF RECURRENT PNEUMOCYSTIS PNEUMONIA AND TOXICITY IN AIDS PATIENTS TAKING PYRIMETHAMINE-SULFADOXINE PROPHYLAXIS.

Miller, Laurel; Cohn, D. Denver Disease Control Service (DCS), Denver, CO, USA.

Objective: To evaluate recurrence rates of Pneumocystis pneumonia (PCP) and toxicity in AIDS patients (pts) receiving pyrimethamine-sulfadoxine (P-S) for secondary prophylaxis of PCP.
Methods: A retrospective analysis was done of all pts at DCS's AIDS Clinic who received P-S from March 1987 through December 1988. All patients had AIDS and at least one episode of PCP prior to initiation of P-S, and were on variable doses of zidovudine (AZT).
Results: There were 38 pts who received both AZT and P-S (1 tablet weekly) from 0.5 to 22 mos (mean 6 mos). They were followed for 3 to 41 mos (mean 15.5 mos) from time of first episode of PCP. Four pts were lost to follow-up, 2 were noncompliant, and 2 had non-PCP related deaths while taking P-S. Of the remaining 30, 9(30%) had recurrent PCP, 14 (47%) discontinued P-S due to adverse reactions, 3 discontinued P-S to receive another form of prophylaxis, and 4 remained on P-S. Adverse reactions included maculopapular rash (4), Stevens-Johnson syndrome (3), hematologic abnormalities (4), elevated liver function tests (2), and malaise (1). The 9 pts who developed PCP took P-S for 4-12 mos (mean 7.4 mos), and recurrences occurred 6-11 mos (mean 9.8 mos) after first episodes of PCP. Eight pts had positive sputum Giemsa stains, and 1 had presumptive PCP; 7 required hospitalization. Of the 16 who discontinued P-S for adverse reactions or noncompliance, 5 developed recurrent PCP 1-7 months after discontinu-ation, none of whom received another form of PCP prophylaxis.
Conclusion: Recurrence rates of PCP in pts taking P-S (30%) were higher than those reported previously and P-S was poorly tolerated, requiring discontinuation in an additional 47% of evaluable pts. Life threatening toxicity developed in 10% (Stevens-Johnson Syndrome). Controlled, prospective trials are necessary to establish the most effective and least toxic regimen(s) for prophylaxis of PCP in AIDS.

T.B.P.44

PRIMARY VERSUS SECONDARY PCP PROPHYLAXIS

Slavin, M.; Hoy,J.; Mijch, Anne; Lucas,C.R..
Fairfield Infectious Diseases Hospital, Melbourne, Victoria, Australia.

Objective. To compare the efficacy of primary and secondary PCP prophylaxis.
Methods. From November 1986, all patients whose CD4 cell count fell below 200/ul, or who developed an AIDS defining illness (ADI) other than PCP, were offered primary (1°) prophylaxis with either dapsone 100mg twice weekly, sulphadoxine-pyrimethamine one tablet weekly, or nebulized pentamidine 400mg monthly. Secondary prophylaxis was given to all patients following treatment for their first episode of PCP. One of the above agents or TMP-SMX one bid was used. All but 9 patients received AZT during the study period. Endpoints of the study were PCP, or death. Follow-up continued to December 1988.
Results. 107 pts received 1° prophylaxis and 93 pts received 2° prophylaxis.

Development of PCP on	1° prophylaxis	2° prophylaxis
Dapsone	25/81 (31%)	19/48 (40%)
Sulphadoxine/pyrimethamine	3/18 (17%)	6/14 (46%)
Pentamidine	1/8 (13%)	1/20 (5%)
TMP-SMX	0	2/12 (17%)
Total	29/107 (27%)	28/93 (30%)
Mean time to PCP	8.9±6.7 mths	9.6±6.7 mths
Mean PCP-free interval	10.9±7.2 mths	7±4.9 mths
Deaths	10	9
Toxicity	13	4

Conclusion. There was no difference in efficacy of primary versus secondary prophylaxis for PCP.

T.B.P.45

SECONDARY PROPHYLAXIS OF PNEUMOCYSTIS CARINII PNEUMONIA WITH SYSTEMIC PENTAMIDINE

Winslow, Dean*; Bincsik, A.; Lincoln, P.; Smolka, H. and Holloway W.
*Medical Center of Delaware, Wilmington, DE, USA.

Objective. To determine the efficacy of intermittent systemic pentamidine for secondary prophylaxis of PCP in AIDS.
Methods. Since January 1987, all patients with histologically-confirmed PCP who gave consent and had adequate peripheral venous access were acutely treated with a 21 day course of either TMP/SMZ or pentamidine, then given pentamidine 4 mg/kg IV weekly x 4, then 4 mg/kg IV every 4 weeks. Most patients also received zidovudine concomitantly with maintenance pentamidine.
Results. Eighteen patients were followed for a mean of 8.5 months to date (range 2-23 months). Three episodes of PCP occurred, but all were mild cases, none of which required ventilatory support. No deaths from secondary cases of PCP have occurred to date. Glucose intolerance developed in one patient after a 21 day course of daily pentamidine followed by 2 months of q. 4 week treatment.
Conclusion. Secondary prophylaxis of PCP with systemic pentamidine is effective in preventing mortality from recurrent pneumocystis pneumonia Larger prospective studies should be done to optimize pentamidine dose and compare this modality to other PCP prophylactic regimens.

T.B.P.46

CLINICAL AND PHARMACOKINETIC INTERACTIONS OF COMBINED ZIDOVUDINE (ZDV) THERAPY AND SULFADOXINE-PYRIMETHAMINE (FANSIDAR) PROPHYLAXIS IN POST-PCP AIDS PATIENTS (ACTG 021).

Hardy, W.David*; Holzman, R.S.**; Avramis V.***; Bawdon, R.+; Fall, H.*; Feinberg, J.++.
Univ. of Calif. - Los Angeles, Los Angeles, CA, USA, **New York Univ., NY, USA, ***Children's Hospital, Los Angeles, CA, USA, +Univ. of Texas Health Science Center, Dallas, TX, USA, +++NIAID AIDS Treatment Program, Bethesda, MD, USA.

Objective. Combination anti-retroviral and PCP prophylactic therapy are commonly used in HIV-infected patients. Potential clinical and pharmacokinetic interactions of combined ZDV and secondary PCP prophylactic therapies are investigated in this study. Data from the ZDV/Fansidar cohort are reported.
Methods. 30 AIDS patients recovered form an initial episode of PCP are randomized equally to receive ZDV (200 mg q 4h) plus either TMP-SMX (1 DS qd, 7d/wk) Fansidar (1 tab/wk) or aerosol pentamidine (150 mg q 2 wks). Intensive clinical, biochemical, hematologic, and pharmacokinetic parameters are followed for one year. Among 5 patients receiving ZDV/Fansidar, no significant clinical (specifically rashes), hematologic, biochemical abnormalities have developed nor PCP recurrence over a mean 16 week (range 8-24 weeks) follow-up period. ZDV pharmacokinetic analyses have shown a prolongation in time to peak ZDV concentration from 0.5hr. to 2.5hr., and an increase in $t_{1/2}$ from 1.0 hr to 2.0 hr. following the addition of Fansidar in 3 of 5 patients. Steady state ZDV concentration has increased from 0.6-0.8 uM to 4.9 uM after 6 weeks of combined therapy in 3 of 5 patients as well.
Conclusion. These data indicate that ZDV and Fansidar are clinically well-tolerated and effective but dosage adjustment may be necessary due to possible pharmacokinetic interaction of the 2 drugs over time.

T.B.P.47

UTILISATION DU FANSIDAR POUR LA PROPHYLAXIE DE LA PNEUMOCYSTOSE ET DE LA TOXOPLASMOSE.

LIVROZET Jean-Michel*, MOUNILAILA K.*, GARIN J.P.**, MOJON M.**, GARNIER J.L.* & TOURAINE J.L.*
*HOPITAL E. HERRIOT, PAV.P, PLACE D'ARSONVAL, 69437 LYON CX3
**FACULTE ROCKFELLER, 8 AVENUE ROCKFELLER, 69008 LYON, FRANCE

Objectif : Evaluer l'efficacité de l'association sulfadoxine-pyrimétamine (Fansidar) en prophylaxie primaire de la pneumocystose et de la toxoplasmose cérébrale chez des patients infectés par le VIH.
Méthodes : 42 sujets (39 hommes et trois femmes) ont reçu 3 comprimés de Fansidar tous les quinze jours et une supplémentation en acide folique (Spéciafoldine 1 comprimé par jour ou Lederfoline 50 mg 1 ampoule per os une fois par semaine). Ces patients avaient un taux de lymphocytes T4 inférieur à 200/mm³ et n'avaient pas eu de pneumocystose ou de toxoplasmose préalables. 17 étaient asymptomatiques, 10 présentaient un ARC et 15 un SIDA. La durée moyenne du traitement a été de 304 jours (de 15 à 923 jours).
Résultats : Aucun cas de pneumocystose ou de toxoplasmose n'a été observé chez les malades traités. Les effets secondaires observés ont été mineurs : 5 cas d'allergie cutanée(11,9%), 1 cas de leuconeutropénie (2,38%) et un cas de céphalées (2,38%) ayant nécessité l'arrêt du traitement. Une anémie macrocytaire a été observée chez un seul malade qui ne prenait pas la prescription d'acide folique.
Conclusion : La tolérance et l'efficacité de la prophylaxie primaire de la pneumocystose et de la toxoplasmose par le Fansidar apparaît, à la dose de 3 comprimés tous les 15 jours, meilleure que celle rapportée dans les études antérieures réalisées à des posologies différentes.

T.B.P.48

PYRIMETHAMINE-SULFADIAZINE IN THE PROPHYLAXIS OF PNEUMOCYSTIS CARINII PNEUMONIA IN AIDS PATIENTS WITH CEREBRAL TOXOPLASMOSIS

Pierone, Gerald; Turett,G., Masci,J., and Nicholas,P.
Mt. Sinai School of Medicine, Elmhurst Hospital Center,Elmhurst, N.Y., U.S.A.

Objective. To determine if maintenance therapy with sulfadiazine-pyrimethamine (SP) in patients with central nervous system toxoplasmosis (TOXO) and the acquired immunodeficiency syndrome (AIDS) is effective in the prophylaxis of Pneumocystis carinii pneumonia (PCP) or if such patients require additional preventive therapy.
Methods. We reviewed the records of patients maintained on SP following an initial episode of TOXO. The diagnosis of TOXO was established by the presence of typical ring-enhancing lesions on brain CT scan and clinical and radiographic response to therapy with SP in patients at high-risk for HIV infection.
Results. 20 patients who had received at least 3 months of SP, including 3 who had had previous or coincident PCP, were identified. The dosage of sulfadiazine ranged from 2-6 grams per day, pyrimethamine 25-50 mg. per day. Zidovudine was also administered to 6 patients (35 patient-months). During 162 patient-months of followup, none of the patients developed PCP (mean 8.1 months, range 3-20 months).
Conclusion. Maintenance therapy with SP provides effective prophylaxis of PCP in patients with AIDS.

Prophylaxie par la pentamidine
Prophylaxis with Pentamidine

T.B.P.49 PREVENTION DES RECHUTES DE PNEUMOCYSTOSE PAR LES AEROSOLS DE PENTAMIDINE : ETUDE PROSPECTIVE RANDOMISEE CHEZ LES PATIENTS SIDA TRAITES PAR AZT.

Girard, Pierre Marie*+ ; Landman, R* ; Gaudebout, C** ; Leprêtre, A* ; Michon, C* ; Saimot, AG*
*Hôpital Bichat - Claude Bernard, *+INSERM U13, 75019 Paris, France.

Objectif. Evaluer l'efficacité et la tolérance des aérosols de Pentamidine (APM) dans la prévention des rechutes de pneumocystose (PCP).
Patients et méthodes. 51 patients ayant présenté une PCP récente (moins de 5 mois) et ne recevant pas de prophylaxie anti-Pneumocystis ont été randomisés : Groupe I : AZT plus APM, Groupe II : AZT seule. Les APM ont été délivrés tous les 15 jours le 1er mois puis tous les mois à la dose de 4 mg/kg par un appareil ultrasonique. Les doses initiales d'AZT de 1200 mg/j étaient adaptées selon la tolérance hématologique.
Résultats. Les deux groupes étaient comparables sur le plan des critères démographiques de la gravité du déficit immunitaire et du suivi de l'AZT. Parmi les 48 patients évaluables, le nombre de rechutes après un recul moyen après la PCP de 9,4 mois a été de 2/22 (9 %) dans le Groupe I et 16/26 (61 %) dans le Groupe II. Aucune réaction d'intolérance systémique n'est survenue. Les principaux effets secondaires étaient la toux (41 %) et une gêne respiratoire au décours de l'inhalation (32 %), conduisant à un seul arrêt prématuré.
Conclusions. 1) Les rechutes de PCP sont fréquentes chez des patients traités par AZT. 2) Les aérosols de Pentamidine diminuent le risque de PCP. 3) L'intolérance bronchique est le principal effet secondaire observé.

T.B.P.50 COMPLIANCE AND LABORATORY DATA PREDICT RELAPSE RATE OF PNEUMOCYSTIS CARINII PNEUMONIA (PCP) DURING PROPHYLAXIS WITH AEROSOL PENTAMIDINE

Opravil, Milos; Weber, R.; Lederberger, B.; Speich, R.; Siegenthaler, W. and Lüthy, R.
Department of Medicine, University Hospital, Zürich, Switzerland.

Objective. To assess the effect of patients' compliance during pentamidine prophylaxis (PX) and of laboratory data during the initial PCP episode on PCP relapse rate (PCPR).
Methods. The inhalation compliance of all 44 AIDS patients treated with aerosol pentamidine (60 mg every 2 weeks) for PX of PCPR and the laboratory data during the initial PCP episode were retrospectively analysed. Laboratory data for lymphocyte subpopulations and serum lactate dehydrogenase (LDH) were available for 30 patients. All PCPR were recorded. Patients who missed ≥ 3 inhalations and at least 15% of all scheduled ones were stratified into the non-compliant Group A, all others into the compliant Group B.
Results. Median duration of pentamidine PX was 31 weeks (range 2 - 77 weeks). During this period 10 PCPR occurred (2.8 per 100 patient-months). Two of them were fatal. Only 16 patients had 100% compliance. Two patients suffered a second PCPR, both after repeated PX non-compliance.

Group	Patients	1st PCPR	Median PX duration	PCPR probability/1st year (95% C.I.)	
A	14	5	28.4 weeks	65%* (32% - 95%)	*p < 0.05 (life-table,
B	30	5	30.2 weeks	18,2%* (6% - 40%)	Peto-Peto Wilcoxon test)

Parameter	Assumed change	Increased relative risk for PCPR/assumed change	
% missed PX	10% up	1.5*	*p < 0.05, univariate Cox regression, 44 patients)
CD4 cells	20% down	2.1**	**p < 0.05, multivariate Cox regression, 30 patients)
LDH	200 U/l up	2.1**	

Conclusion. Poor compliance with prophylactic pentamidine inhalations leads to a significantly higher rate of PCPR. The laboratory values significantly associated with higher rate of PCPR were elevated levels of LDH and depressed levels of CD4 lymphocytes during the initial PCP episode.

T.B.P.51 SUCCESSFUL CHEMOPROPHYLAXIS OF PCP BY POSTURAL INHALATION AND LOW DOSE AEROSOLIZED PENTAMIDINE

Keyes, Craig; Rodgers,P; Marte,C; Wolbert, J; Kelly,J; Ribble,D.
Bellevue Hospital Center/Community Health Project, NY, NY USA.

OBJECTIVE: To evaluate the efficacy of low dose aerosolized pentamidine when administered by postural inhalation. METHODS: 97 patients[52 AIDS(37 S/P PCP) 45 ARC] intolerant of sulfa drug PCP prophylaxis were followed for a median of 11 months(range 5-19). Pentamidine isoethionate was administered by Pulmosonic nebulizer(2.5-3.5 microns) at a dose of 60 mg. every 3 weeks via postural inhalation, i.e., in the supine and left and right lateral decubitus positions each for 10 minutes. Those experiencing bronchospasm were subsequently prophylaxed with albuterol inhalent prior to each pentamidine administration. RESULT: Of 97 patients followed at this dose for a median of 11 months there were 3 episodes of PCP(1 AIDS, 2 ARC). All 3 episodes were diffuse in nature and were successfully treated with IV pentamidine. All 3 episodes occurred in noncompliant patients who had missed 2 or more consecutive doses(accounting for a 9 week or greater interval between doses). There were no severe adverse reactions to the drug. Minor adverse effects included: cough-46(47%), bronchospasm-14(14%) and metallic taste-58(60%). No episodes of PCP occurred in patients compliant with the protocol.
CONCLUSION: Postural inhalation may allow for improved efficacy and/or reduced dose of prophylactic aerosolized pentamidine. Controlled trials with larger numbers, more efficient nebulizers and of longer duration are indicated.

T.B.P.52 HOME AEROSOLIZED PENTAMIDINE PROPHYLAXIS IN AN INNER CITY POPULATION.

Samuels, Jonathan*, Hilton, M., Hendrix, J., Small, C.B.
North Central Bronx Hospital/Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, New York, U.S.A.

OBJECTIVE: To determine efficacy, tolerance and compliance (comp) with home aerosolized pentamidine (AP) prophylaxis in AIDS and ARC patients (pts) of poor, minority and intravenous drug use background in a NYC clinic.
METHODS: Pts received instruction in the use of the Pulmosonic® Nebulizer (PN) and in the preparation of Pentamidine for aerosolilization. Standard dose was 60 mgs. weekly for the first 4 weeks (wks) and biweekly thereafter. Evaluable pts were followed for ≥ 4 wks.
RESULTS: 58 pts were evaluable. 45 males, 13 females; 38 Hispanic, 17 black, 3 white. Mean age 36 (range 22-59). 30/58 (52%) IVDUs, 13/58 (22%) heterosexual partners, 12/58 (21%) homosexuals, 1 (2%) transfusion recipient, 2 (3%) no known risk. 52/58 (90%) had AIDS, 48/58 (83%) status-post PCP. 6/58 (10%) had ARC with low CD4 (mean:87). 6/58 (10%) had asthma. Pts were followed for a mean of 23 wks (range 4-44 wks), total 1307 pt wks. 57/58 (98%) were also on AZT. 9/58 (16%) developed PCP; all were noncomp with AP for at least 4 wks prior to PCP. Reasons for noncomp in the 9 pts included: drug use (3), AP-induced respiratory symptoms (2), fear of treatment (Rx) (2), poor understanding of AP importance (2). 5/9 with PCP (56%) were also noncomp with AZT. Of 48 pts receiving AZT who did not develop PCP, 10 (21%) were comp with <50% of AP Rxs: 4 (8%) were comp with >50% but <100% of AP Rx: 34 (71%) were comp with 100% of AP Rx. 4/48 (8%) were also noncomp with AZT.
CONCLUSION: Home AP by PN is a safe, effective method of PCP prophylaxis in an inner city population of primarily IVDUs. AP comp was less than AZT comp.

T.B.P.53 LONG TERM SAFETY AND EFFECTIVENESS OF AEROSOL PENTAMIDINE FOR PREVENTION OF PNEUMOCYSTIS CARINII PNEUMONIA

Bernard, Edward M.; Dickmeyer, M.S.; Schmitt, H. and D. Armstrong. Memorial Sloan-Kettering Cancer Center, New York, New York, U.S.A

Objective. To determine the safety of aerosol pentamidine and its effectivness in preventing PCP compared to historical controls.
Methods. Aerosol pentamidine was administered weekly for four weeks and then biweekly at a dose of 60 mg via and ultrasonic nebuliser (Fisoneb). Toxicity was judged based on examinations, pulmonary function, hematologic, and biochemical tests. Efficacy was judged based on comparison of rates of PCP versus NIAID protocol 002.
Results. A total of 266 participants were treated for 1-20 months (9.6 ± 5.2 mos). Most were homosexual men; 90% had AIDS; 71% had a previous episode of PCP. At entry the mean time since diagnosis of AIDS was 11.7 ± 10.1 mos. There were no serious adverse reactions and no systemic toxicity was seen; 14.2% of patients required a bronchodilator; 91% of patients had a stable or improving pulmonary function. There were 49 withdrawals and 72 deaths. A total of 25 cases of PCP occurred; the occurence rate was 3.8% among patients (n=80) with no previous episodes; it was 4.9% among those (123) with one episode; it was 25.4% among those (63) with two or more previous episodes. There were 6 pneumothoraces and 3 cases of extrapulmonary pneumocystosis. Based on historical controls, there was a 16-fold reduction in the recurrence rate of PCP among patients who had one previous episode.
Conclusion. Aerosol pentamidine was safe and it prevented PCP. Higher or more frequent doses may be needed as immune deficiency progresses.

T.B.P.54 AEROSOLIZED PENTAMIDINE FOR THE SECONDARY PROPHYLAXIS OF PNEUMOCYSTIS CARINII PNEUMONIA IN THE ACQUIRED IMMUNODEFICIENCY SYNDROME: A REPORT FROM THE CANADIAN COOPERATIVE TRIAL. *

Montaner, JSG; Lawson, L; Falutz, J; Hyland, R; Rachlis, A; Gervais, A; Rouleau, P; McFadden, D; Fong,IW; Garber, GE; Martel, A; Schlech, W; Louie, T, Chan, C. , Vancouver, BC, Canada

OBJECTIVE. To evaluate the safety and effectiveness of aerosolized pentamidine for the secondary prophylaxis of Pneumocystis carinii pneumonia (PCP) in the acquired immunodeficiency syndrome (AIDS).

METHODS. Trial Design: randomized, double blind, placebo-controlled. Inclusion Criteria: (I) Recovered from first episode of AIDS-related PCP within 2 to 24 weeks, (II) No other AIDS defining opportunistic infection or active pulmonary pathology (III) No antiretroviral or immunomodulating agents (except AZT) during the study or within 30 days of entry (IV) Pulmonary function test VC ≥ [illegible] of predicted; FEV-1 ≥ 65% of total FEV and corrected DLCO >60%. Intervention: Patients were randomly allocated to receive pentamidine 60mg per dose or placebo. The study drug was delivered via a hand held ultrasonic nebulizer (FISONEB®, MAD=2.5-5.0, microns [depending on the sizing technique]) in a supervised fashion over 15 to 20 minutes. Patients received 5 doses during the initial 14 days followed by one dose every 2 weeks for a total of 24 weeks. Follow-up: Complete history, physical and laboratory evaluation including PFT's were performed at regular intervals. Anti-PCP medications were prescribed unless PCP was documented.

RESULTS. 162 patients from 16 centres were randomized at the time the study was terminated. A total of 32 cases of PCP were diagnosed, 27 of them occurred among the 78 placebo treated patients while 5 occurred among the 84 patients receiving aerosolized pentamidine (p<.0001 Chi square). Median follow-up was not significantly different in both groups.

CONCLUSION. Aerosolized pentamidine is highly effective in the secondary prophylaxis of AIDS-related PCP.

* Supported by a grant from Fisons Co.

T.B.P.55 PROPHYLACTIC INHALATION PENTAMIDINE IN PATIENTS WITH HIV DISEASE

Ernst,Jerome A.*; DiPasquale,L.*; Sy,E.R.*; Rubinstein,D.*
*Bronx Lebanon Hospital, Bronx, NY, USA.

Objective. To evaluate inhalation pentamidine in the prophylaxis of PCP in immunosuppressed HIV positive patients.
Method. We prospectively studied 46 HIV positive immunodeficient patients. 200 mg of pentamidine in 4 cc sterile water were delivered by inhalation every other week using an Aerotec II apparatus. Three groups of patients were studied. 1. 10 HIV positive patients with a T4 count less than 250 LZ and no history of PCP. 2. 9 HIV positive patients with a history of PCP but no tissue documentation. 3. 27 HIV positive patients with biopsy-proven PCP.
Results. 46 patients were treated an average of 20.8 weeks. There were 5 episodes of presumed PCP pneumonia. 8 patients were lost to followup. The overall recurrence rate was 13.2%. The results in each group are as follows:

Group	Average Treatment Time	(Range)	Recurrences	Rate
1	5.8	(2-20)	0	0
2	4.3	(2-20)	1	16.7%
3	7.7	(2-36)	4	18.0%

All 5 of the patients who developed pneumonia were treated with anti-PCP therapy. 3 of these 5 patients died.
Conclusion. We noted an overall recurrence rate of 13.2% in patients on aerosolized pentamidine which is below that reported for patients without prophylaxis. Although our numbers are small the study is ongoing. The fact that the majority of our patients were IVDA's and still followed the treatment protocol is encouraging.

T.B.P.56 A CLINICAL EXPERIENCE WITH AEROSOLIZED PENTAMIDINE (AP).

SD Nightingale, RS Ferguson, SM Pounders, JD Jockush & KJ Robertson. Parkland Memorial Hospital, Dallas, TX, USA.

Since 6/22/88 we have treated 308 HIV positive patients with AP 300 mg q month for 112 +/- 80 days. Four withdrew after 1 treatment because of cough; treatments were otherwise uncomplicated. Serial pulmonary function tests in 24 patients before and after 6 months of treatment were:

	FEV1(%pred)	FVC(%pred)	FEV25-75(%pred)	DLCO(cor for Hb)
Pre	94	86	113	20.2
Post	92	94	91	21.3
P	NS	<.01	<.01	=.0502

14 patients developed PCP while on AP: 1/99 with ARC or CD4 <400, 2/56 with AIDS but no prior PCP, and 11/153 with AIDS and prior of PCP. These 11 had had their 1st PCP an average of 422 (range 253-908) days before starting AP. 5/11 (45%) of the recurrent PCP episodes were fatal, and 2 were complicated by pneumothoraces. For comparison, from 7/1-12/31/88 we saw 93 1st PCP cases in patients not on AP of which 22 (24%) were fatal and 2 were complicated by pneumothoraces. Finally, 3/153 developed bacterial pneumonia that responded to antibiotic therapy.

This uncontrolled experience suggests that AP may reduce the frequency, but not the severity, of PCP in HIV positive patients. While AP was well tolerated and DLCO stable, a decrease in small airway flow (FEF25-75) appears to be a subclinical but statistically significant complication of therapy.

T.B.P.57 ABSOLUTE PULMONARY DEPOSITION OF NEBULISED PENTAMIDINE ISETHIONATE

Thomas, Simon; O'Doherty, M.; Page, C.; Barlow, D.; Croft, D. and Bateman, N.
St. Thomas' Hospital, London, UK.

Objective. To measure the absolute pulmonary deposition of two doses of pentamidine administered using two different nebuliser systems.
Methods. Following salbutamol pre-treatment, 8 patients with AIDS inhaled 50 and 150 mg pentamidine mixed with 37 MBq (0.05 mg) 99mTc human serum albumin (total volume 3 ml) via two nebuliser systems, System 22 Mizer (S22M, Medicaid UK) and Respigard (RII Marquest) using gas flow of 6 L/min. Pulmonary and non-pulmonary (oropharyngeal and gastric) deposition was measured using a gamma camera and absolute deposition calculated using a correction derived from lung phantom studies. Spirometry was measured before and after salbutamol and after pentamidine inhalation and adverse effects were recorded.
Results. Absolute pulmonary pentamidine deposition (mg±SEM) results are shown in the table:

	S22M		RII	
Nebuliser dose	Both lungs	R lung	Both lungs	R lung
50 mg	2.78±0.42	1.46±0.22	1.53±0.31	0.82±0.15
150 mg	7.24±0.16	3.74±0.63	4.47±0.53	2.42±0.32

S22M delivered more drug to the lungs and in a shorter time, with over 90% deposited within 10 min. RII produced less pulmonary and non-pulmonary deposition and fewer adverse effects. Inhalation of 150 mg pentamidine produced small reductions in FEV1 with both S22M (16.2%, p<0.01) and RII (7.5%, p<0.01).
Conclusions. Pulmonary pentamidine deposition was greatest using S22M but RII was associated with fewer adverse effects.

T.B.P.58 AEROSOL PENTHAMIDINE FOR TREATMENT AND SECONDARY PROPHYLAXIS OF PNEUMOCYSTIS CARINII (PCP)

Flamholc, Leo; Haidl, S.; Westin, E. and Prellner, T.
University of Lund, Dept of Infectious Diseases, General Hospital, Malmö, Sweden.

Ten patients with PCP were treated with aerosol penthamidine 400 mg daily for 10 days followed by secondary prophylaxis of 400 mg once weekly. We used the nebulizer Viasol MA2 that produces particles <2 u and has a residual volume of 0.2 ml. Monitoring for assessing effectiveness and side-effects included hemoglobin oxygen saturation during exercise, biochemical parameters, FEV1 and VC. Follow-up bronchoscopy was performed at least once after >30 days of secondary prophylaxis.
Results. 8/10 patients responded to therapy, 2 patients did not and were given trimethoprim-sulfamethoxazol (TS) concomitantly. After improvement TS was discontinued and secondary prophylaxis continued. All patients were negative for pneumocystis at follow-up bronchoscopy. Neither clinical signs nor monitored parameters indicated any relapses. Three patients died after 6 weeks, 6 months and 17 months. At autopsy none of them had pneumocystis.
Conclusions. In our study aerosol penthamidine was effective for PCP in 8 of 10 patients. Controlled studies are needed to establish its role in the treatment of PCP. There is also a need to compare different nebulizers. In 10 patients given secondary prophylaxis we observed no relapses. We find this very encouraging. Despite the high dose given no adverse effects were observed besides ligth cough and complaints of unpleasant taste.

T.B.P.59 PROPHYLACTIC TREATMENT WITH AEROSOL PENTAMIDINE TO PREVENT RELAPSE OF PCP.

Birgitte Nybo Jensen*, TL Nielsen**, B Lerche*, V Backer*, L Mathiesen**, P Skinhøj*.
* State University Hospital, Copenhagen;
**University Hospital, Hvidovre, Copenhagen, Denmark.

Objective: To evaluate the efficacy of aerosol pentamidine in the prophylaxis of PCP relapses.
Patients: 45 AIDS patients were prophylactically treated with aerosol pentamidine 60mg every 2 weeks, with an Acorn System 22. The patients had all experienced an episode of PCP 2.5 months (± 4) before start of treatment. Time from AIDS diagnosis to start of prophylaxis was 1 - 22 months (mean 7.4).
Results: The patients were treated for 1 - 22 months (mean 8.4). No significant adverse reactions were seen.
Failing patient compliance in 2 patients, were followed by relapse of PCP. Of the remaining 43 patients, 2 mild cases of PCP occurred after 8 respectively 9 months of treatment. One were clinically suspected, one histologically verified.
The relapse rate of PCP per 100 patient months were 0.54% among patients treated with this regimen.
Conclusion: Pentamidine aerosol seems to be effective as prophylaxis against relapse of PCP in this regimen. Only mild side effects were observed. A controlled study comparing aerosol pentamidine with co-trimoxazole is in progress.

T.B.P.60 EFFICACY OF MONTHLY INTRAMUSCULAR PENTAMIDINE IN THE PROPHYLAXIS OF RECURRENT PNEUMOCYSTIS CARINII PNEUMONIA

Miller,Steven and Sifris,Dennis. HIV Clinic, Johannesburg Hospital, Johannesburg, South Africa.

Objective. To evaluate the efficacy of monthly intramuscular pentamidine in the prophylaxis of recurrent Pneumocystis carinii pneumonia (PCP) in pepple with AIDS.
Methods. Fifteen patients who have previously experienced at least one episode of PCP were enrolled in the study. Their ages ranged from 23 to 42 years. All had peripheral blood T helper/inducer cell counts of 400/mm^3. Three patients were receiving zidovudine 1200mg daily. Prophylaxis with cotrimoxazole was precluded in 13 patients because of hypersensitivity and in 2, because of severe leucopenia. Pentamidine isethionate (Maybaker) 200 mg was administered as a monthly intramuscular injection. Patients were prospectively assessed for adverse effects and recurrence of PCP.
Results. Duration of pentamidine prophylaxis has ranged from 6 to 24 months and there has been no recurrence of PCP. Nine patients have died from other AIDS-related conditions since enrollment. Pain at the injection site for 24 to 48 hours was reported by all subjects. One patient developed a sterile abscess following the injection. Hypotension and hypoglycaemia were not documented.
Conclusions. 1) Monthly intramuscular pentamidine isethionate provides effective prophylaxis for recurrent PCP. 2) Side effects are generally minor. 3) Monthly intramuscular pentamidine is more cost effective than weekly aerosolised pentamidine. 4) Intramuscular pentamidine is easy to administer and should be considered where there are no facilities for nebulisation.

T.B.P.61 PHARMACOKINETICS OF AEROSOLIZED PENTAMIDINE IN AIDS PATIENTS BEING TREATED FOR ACUTE PNEUMOCYSTIS CARINII PNEUMONIA.

Yana J.Paulson*, RJ Ko*, RT Koda*, CT Boylen**, TM Gilman*.
Schools of Pharmacy* and Medicine**, University of Southern California, Los Angeles, California, U.S.A.

OBJECTIVE: To study the pharmacokinetics of aerosolized pentamidine in AIDS patients who are receiving treatment for mild episodes of Pneumocystis carinii pneumonia.
METHODS: Seven patients received investigational treatment with pentamidine (600 mG/day over 30 min) via the Respigard II nebulizer. Serial blood specimens were obtained from each patient on 3 occasions (days 1, 14, and 21). Serum pentamidine concentrations were measured by high-pressure liquid chromatography.
RESULTS: Maximum concentrations were 14.4 ± 5.3 nG/mL in samples obtained 1 to 5 minutes after completion of the dose. The rate of disappearance from serum was rapid and serum concentrations were undetectable 45-60 minutes after each inhalation treatment. There was no difference in the magnitude of the peak concentrations between day 1, day 14, and day 21 of therapy.
CONCLUSION: No serum accumulation of the drug was noted over the 21 day period of treatment. Urine concentrations are needed to better characterize the pharmacokinetic parameters of inhaled pentamidine.

T.B.P.62 COMMUNITY STUDY OF THE EFFICACY OF INHALED PENTAMIDINE ON THE PREVENTION OF PNEUMOCYSTIS CARINII PNEUMONIA - CONTINUING EXPERIENCE.

Weisman, J; Gilman, TM; Rogolsky, E; Rothman, P; Scarsella, A; Eppolito, L; Hitt, S; Boylen, CT. LAC-USC Medical Center, GH 11-900, 1200 North Street, Los Angeles, CA, U.S.A.

Of the 150 patients receiving inhaled pentamidine prophylaxis to prevent Pneumocystis carinii pneumonia (PCP) reported last year, 56 are now deceased. None of these patients died of PCP. Four patients have had recurrent PCP. Those who have developed recurrent PCP have tended to have multiple mild episodes. Five patients have developed pneumothoraces while on this regimen, all after having at least one episode of PCP. Two of these patients required surgical intervention. None of the patients have developed clinically significant side effects from the inhaled pentamidin such as hypoglycemia, pancreatitis, or impairment of renal function. Serial spirometric determinations have shown no deterioration during the course of prophylaxis, although some of the patients did have self-limited deterioration in pulmonary function during acute infectious exacerbations. We conclude that inhaled pentamidine is effective prophylaxis in preventing recurrent PCP.

T.B.P.63 INHALED PENTAMIDINE AS PRIMARY PROPHYLAXIS IN A HIGH RISK GROUP - CONTINUING EXPERIENCE

Weisman J; Paulson, YJ; Rogolsky, E; Rothman, P; Scarsella; Hitt, S; Eppolito, L; Boylen, CT. LAC-USC Medical Center, GH 11-900, 1200 North Street, Los Angeles, CA 90033, U.S.A.

We have given inhaled pentamidine prophylaxis to 250 patients who are in a high risk group for PCP with T_4 counts below 400. These patients have received 150mg of inhaled pentamidine bi-weekly from 6 months to 21 months. None of the patients have developed pneumocystis pneumonia in this time interval. None of the patients have developed hypoglycemia, impaired renal function, or pancreatitis from their prophylaxis. Pulmonary function studies have been obtained at periodic intervals and no deterioration has been seen in spirometric values. No pneumothoraces have developed in this group. We conclude that primary prophylaxis with inhaled pentamidine in this high risk group appears to offer significant promise without apparent risk. We believe that further controlled studies of primary prophylaxis urgently need to be done in these seriously immuno-compromised patients.

T.B.P.64 COMPARISON OF NEBULISER EFFICIENCY FOR AEROSOLISING PENTAMIDINE

Smith, Don; Erskine D.; Steele, J.; Mills, D.; Gazzard, B.G.
St. Stephen's Hospital, London, England.

Objectives To determine which is the most efficient nebuliser system when used to aerosolise 300mg of Pentamidine isethionate (May & Baker Ltd.) in terms of droplet size, aerosol output and nebulisation time.
Methods The following brands of nebuliser were assessed: Acorn System-22 (Medic-AID Ltd.) with and without Mizer attachment, Respigard II (Marquest Medical Products) and Fisoneb (Fisons Corp.). Four models of each brand of jet nebuliser were tested at flow rates of 8L/min., the Fisoneb was tested at maximum setting. Droplet size was assessed using a Malvern Instruments 2600HSD laser particle and droplet analyser - aerosol output was assessed by spectrophotometry of solution remaining within the nebuliser. The nebulisation time was also recorded.

Results	Flow Rate	MMD(um)	%<5.0um	Amount <5um	Neb time(min)
ACORN	8L/min	2.5	74.6%	143.6mg	15.5
ACORN+MIZER	8L/min	3.9	63.1%	ND	ND
RESPIGARD II	8L/min	1.2	96.3%	127.3mg	18.2
FISONEB	-	4.7	56.3%	82.7mg	4.0

Conclusions The Respigard II nebulisers produced the greatest amount of small droplets but aerosolised the least amount of drug. The Acorn aerosolised the largest amount of drug of sufficient droplet size to achieve alveolar deposition.

T.B.P.65 EFFECT OF AEROSOL CHARACTERISTICS ON PULMONARY DEPOSITION OF PENTAMIDINE

Simonds, Anita; Newman, S; Johnson, M; Talaee, N; Lee, C; Clarke, S.
Royal Free Hospital, London, UK.

Objective. An evaluation of pulmonary delivery of aerosol pentamidine relating alveolar deposition and side effects to droplet size profile of nebuliser.
Methods. In a single blind crossover study, 9 patients with AIDS and stable respiratory status received 150 mg radiolabelled pentamidine isethionate from A) Respirgard II nebuliser (Marquest) B) Respirgard II nebuliser with inspiratory baffle removed and C) Acorn System 22 nebuliser (Medic Aid). In 6 patients an Acorn nebuliser modified by addition of an inspiratory baffle (one-way valve insert, Inter-Surgical) was studied (D). Alveolar deposition (24 hour whole lung retention of radioactivity), incidence of cough and breathlessness and pulmonary function were measured. Droplet size profiles from the nebuliser systems A-D were characterised and expressed as % droplet mass < 2 um (P2), mass median diameter (MMD) and maximum droplet size (dmax).
Results. Droplet size profiles (P2, MMD, dmax) were A) 78.9, 1.0 um, 6.9 um, B) 50.5, 1.7 um, 19.3 um C) 39.6, 3.4 um, 25.3 um and D) 72.8, 1.0 um, 8.0 um. Alveolar deposition was directly related to P2 and incidence of cough and breathlessness proportional to dmax. Insertion of an inspiratory baffle into the Acorn System (D) markedly improved alveolar deposition of pentamidine and reduced adverse airway effects.
Conclusion. Optimisation of droplet size profile from nebulisers can enhance alveolar targeting of pentamidine.

T.B.P.66 LOW PCP RELAPSE RATE USING HIGH DOSE (300mgs) NEBULIZED PENTAMIDINE PROPHYLAXIS BUT POOR LONG TERM SURVIVAL.

DON.E.SMITH. D.HERD. D.HAWKINS. B.G.GAZZARD.
ST STEPHENS HOSPITAL, FULHAM ROAD, LONDON, ENGLAND.

OBJECTIVE : To assess the effectiveness of high dose Nebulized Pentamidine on Pneumocystis Carinii Pneumonia (PCP) incidence and whether preventing PCP affects the long term survival in AIDS patients.
METHOD : 94 patients received Nebulized Pentamidine 300mgs fortnightly on a primary or secondary prophylactic basis over an 18 month period. The number of episodes of PCP and number of deaths from HIV were recorded over this period.
RESULTS : Of 47 patients on primary prophylaxis, no episodes of PCP and 1 death were seen (average follow up 4.5 months). Of 47 patients on secondary prophylaxis, only one episode of PCP occurred (average follow up 6.1 months). However, of 29 patients who received greater than six months prophylaxis post PCP over a maximum follow up period of 18 months, 11 (38%) died of other AIDS complications. Average time to death was 6.8 months (range 2-16) after their pneumonia. None of the deaths were caused by PCP.
CONCLUSION : Although Nebulized Pentamidine at a dose of 300mgs/fortnightly is highly effective at preventing PCP, mortality rate post PCP still remains very high.

T.B.P.67

THE EFFECT OF INITIAL PENTAMIDINE SOLUTION VOLUME ON TOTAL PULMONARY DEPOSITION

O'Doherty, Michael; Thomas, S.; Page, C.; Nunan, T. and Bateman, N.
St. Thomas' Hospital, London, UK.

Objective. To assess pulmonary deposition of 50 mg pentamidine when dissolved in 3 or 6 ml solution.
Methods. Following pre-treatment with salbutamol 4 patients with AIDS inhaled 50 mg of nebulised pentamidine made up in a final volume of 3 or 6 ml with 99mTc human serum albumin added as a marker. Each patient received these dilutions from 2 nebulisers, System 22 Miser (S22M, Medicaid UK) and Respigard II (RII, Marquest) at a gas flow rate of 6 L/min. Pulmonary and non-pulmonary (oropharyngeal and gastric) deposition was measured for each dilution and each nebuliser using a gamma camera. Spirometry was recorded before and after each nebulisation.
Results. S22M produced greater deposition than RII for both the 3 and 6 ml dilutions with deposition completed in 10 min and 30 min respectively. For both systems, the 6 ml dilution prolonged pulmonary deposition, reduced adverse effects and increased final pulmonary deposition by over 50% compared with the 3 ml dilution.
Conclusion. The larger volume delayed dynamic deposition but significantly increased total deposition within the lungs. It was preferred by patients but a longer treatment period was necessary.

T.B.P.68

PROPHYLAXIS FOR PNEUMOCYSTIS CARINII PNEUMONIA (PCP): A COST-EFFECTIVENESS ANALYSIS.

Freedberg, Kenneth A; Cohen,CJ; Cotton,DJ and Tosteson,AHA.
Beth Israel Hospital and Harvard Medical School, Boston, MA, USA.

Objective: To determine the cost-effectiveness of primary prophylaxis for PCP in HIV-infected patients.
Methods: Based on T4 lymphocyte count (<200, 200-400, >400) and prophylaxis with trimethoprim-sulfa (TS), aerosol pentamidine (AP), or nothing (NOPRO), we modeled the annual risk of PCP or other AIDS-related complications, and estimated average life expectancies (LE), costs, and marginal costs per year of life saved ($/YLS) with TS or AP. Baseline estimates from the literature and hospital charges when T4<200 included: efficacy of prophylaxis (90%), cost of treating PCP ($6000), probability of AIDS in the first year (30%), probability of PCP if AIDS develops (70%), complication rate of TS (50%).
Results:

	NOPRO	TS		AP (VS NOPRO)		(VS TS)
T4 COUNT	LE	LE	$/YLS	LE	$/YLS	$/YLS
<200	2.2	4.4	$2,300	4.8	$9,900	$50,000
200-400	5.0	5.6	$6,700	5.7	$41,000	$202,000
>400	5.9	6.1	$20,000	6.1	$155,000	$606,000

Results were minimally affected by clinically reasonable changes in estimates. Prophylaxis with dapsone, depending on its efficacy and toxicity, may be as or more cost-effective than TS.
Conclusion: Primary prophylaxis for PCP with TS is more cost-effective than most widely accepted treatments for many diseases. In contrast, AP is more costly than these treatments, except in the highest risk group (T4<200).

T.B.P.69

AEROSOLIZED PENTAMIDINE AS CHRONIC SUPPRESSIVE THERAPY FOR *P. CARINII* PNEUMONIA IN A HETEROGENEOUS AIDS POPULATION

Rodriguez, Kassandra; Deziel, P; Fischl, M. University of Miami School of Medicine, Miami, Florida, USA.

Objective. To evaluate efficacy and safety of aerosolized pentamidine (Pentam) in a non-selected group of AIDS patients who were unable to receive trimethoprim-sulfa (THP/SMX) for *P. carinii* pneumonia prophylaxis.
Methods. A retrospective medical record review of all patients who received aerosolized Pentam at clinic for a minimum of 10 wks and who were not actively enrolled in any experimental protocols from October 1987 through October 1988. Patients were stratified according to type of HIV disease and looking at zidovudine and use of bronchodilators as independent variables.
Results. 124 patients received aerosolized Pentam of whom 97 were evaluable.

Stratification of Patients with Breakthrough Rate

	# pts.	# breakthroughs	%
1° Prophylaxis	28	0	0
2° Prophylaxis	69	10	14
Multiple PCP Episodes	15	4	26
Kaposi's Sarcoma	30	2	6.6
Overall	97	10	10
Use of Bronchodilators	32	4	12.5
Use of Zidovudine	55	7	12.5

Conclusions. Even though bronchospasm was documented in 30% of patients, this was overcome by use of bronchodilators in all cases. No other systemic adverse reactions were documented. Aerosolized Pentam appears to be effective and well tolerated in patients who are intolerant of THP/SMX.

T.B.P.70

Aerosolized Pentamidine (AP) Prophylaxis for Pneumocystis carinii pneumonia (PCP) in a Boston community health center.

Moon, MM, Harris, S, Feldman, R, Mayer, KH. Fenway Community Health Center, Boston, MA., USA.

Objective: To describe the first year's experience with AP treatment(tx) for PCP prophylaxis in a community health center(CHC). Methods: Descriptive and statistical analyses. Results: 150 mg of AP have been administered every 2 weeks via Respigard II nebulizer starting 1/88 to 64 pts. 50 are still in the program--none have died and no relapses were seen in those followed > 1 month. 14 changed providers or moved out of town. Mean age = 37 (range 25-54). 32 had prior PCP, 26 CDC IV non-AIDS, and 6 with other AIDS diagnoses. 20% pre-treat with Alupent. Side effects include metallic taste in mouth in approx. 50% of clients, and asymptomatic post-tx hypotension in 25% of clients. For 40 pts. seen > 1 month, there was an aggregate of 200.5 client months of tx (mean = 5.0 months). 13 have been treated > 6 months. All are on AZT therapy; 2 on AL-721 too, 6 also on acyclovir. Of these 13, 3 have had bacterial pneumonias during AP, one of them X3, all of which have responded to rx. Reimbursement for AP includes 59% third party payors, 25% Medicaid, and 16% self payors. A 10% failure rate in the Respigard II nebulizer system has been noted (leaks, valve sticking). Conclusion: That a CHC setting provides a stable environment for providing AP tx which is well tolerated.

T.B.P.71

PROPHYLAXIE SECONDAIRE DE LA PNEUMOCYSTOSE PULMONAIRE PAR LA PENTAMIDINE EN AÉROSOL

M. Eliaszewicz, F. Lacassin, J. Lebas, MC. Meyohas, M. Perrin, O. Picard
Hôpital Saint-Antoine, Paris, France.

La pneumocystose pulmonaire (PNP) représente l'infection opportuniste inaugurale chez 65% des patients atteints de SIDA et met en jeu le pronostic vital chez un quart d'entre eux. Les taux de rechute après un premier épisode atteignant 35% à 6 mois et 60% à 12 mois, une prophylaxie secondaire paraît indispensable; le cotrimoxazole exposant à des effets indésirables dans 50% des cas, d'autres prophylaxies sont à l'étude dont la pentamidine en aérosol.
Patients et méthodes: 35 patients sous AZT bénéficient d'un aérosol de mésylate de pentamidine (4 mg/kg) tous les 15 jours sur un nébuliseur ultrasonique de Vilbis; 26 d'entre eux sont traités depuis plus de 6 mois. Il s'agit de 25 hommes et 1 femme d'âge moyen 37 ans (26 à 69) dont 25 homosexuels et 1 transfusée. Résultats: L'observance des aérosols est bonne chez les 26 patients; leur tolérance est parfaite chez 19/26 (toux: 6, bronchospasme: 1, neutropénie:14 , manifestations systémiques: 0). 3/26 patients ont rechuté à 6 mois (11,5%, intervalle de confiance à 95% 4-20%). Discussion: La toxicité des aérosols paraît nulle. La méthodologie reste mal standardisée (appareillage, posologie, répartition pulmonaire). Dans la littérature, après 6 mois d'AZT sans autre traitement prophylactique, le taux de rechute de PNP est de l'ordre de 19% ; en prophylaxie secondaire, les aérosols semblent donc apporter un bénéfice modéré chez les patients sous AZT. Conclusion: Les aérosols de pentamidine semblent faire preuve d'une efficacité modérée en prophylaxie secondaire de la PNP du SIDA dans les 6 premiers mois; leur bénéfice reste à comparer à celui d'autres traitements prophylactiques.

T.B.P.72

SINGLE AND MULTIPLE DOSE PHARMACOKINETICS (PK) OF REDUCED DOSE (3 MG/KG) INTRAVENOUS PENTAMIDINE

John E. Conte, Jr.
UNIVERSITY OF CALIFORNIA, San Francisco,California, U.S.A.

Objective: To investigate the single-and multiple-dose PK of reduced dose intravenous pentamidine in AIDS patients with *Pneumocystis carinii* pneumonia (PCP).
Methods: Serial plasma and urine pentamidine concentrations (HPLC) was measured in 6 previously reported patients with normal or near-normal renal function who received 3 mg/kg/day of intravenous pentamidine as a 2-hour timed infusion. Concentration-time data were fit to 2-and 3-compartment (2c or 3c) models with the Prophet Computer Resource.
Results: Plasma concentration (mean ±SD) at the completion of infusion, and at 1,6 and 16 hours following completion of infusion were 221 ± 85.5, 16.6 ± 6.8, 4.0 ± 1.6, and 1.4 ± 2.3 mg/ml. First dose PK parameters are summarized in the table:

	Parameter				
Model	Vol 1 (liters)	VSS (liters)	AUC (mcg hr/ml)	Clearance (1/h)	$T^1/_2$ (h)
2c	66.5±38.3	542±357	513±145	392±102	5.1±3.6
3c	56.5±24.0	140±6.2	924±343	236±38.7	93.6±36

On day 5 (n=4), 7 (n=3), 11 (n=3), 12 (n=2), 13 (n=2) and 18 (n=1) the mean (+SD) plasma concentrations were 10.3 ± 10.1, 24.6 ± 12.2, 34.5 ± 5.3, 48.3 ± 32.9 and 69.6 ng/ml.
Conclusion: The true elimination half-life of pentamidine is long (approximately 4 days) and daily dosing leads to progressive plasma accumulation even in patients with normal or near-normal renal function

T.B.P.73 Nebulized Pentamidine in the primary and secondary Prophylaxis of PcP

Staszewski S., Odewald J., Gottstein A., Rehmet S., Müller R., Stimmel K.H., Helm E.B., Universitätsklinik Frankfurt. Zentrum der Inneren Medizin. Infektions-Ambulanz. FRG.

Although AZT significantly prolongs the survival time after the first PCP episode it does not influence the occurrence of opportunistic infections (OI) principally. Of 185 patients treated with AZT in Frankfurt. 32 (17%) developed PCP. In 12 cases. PCP first occurred under AZT. PCP is the most common OI also under AZT; as a consequence. PCP prophylaxis. aimed at preventing or reducing the occurrence of PCP. is required.

We therefore perform an open study to assess efficacy and tolerance of nebulized pentamidine as primary or secundary PCP prophylaxis. One group of patients additionally gets Fansidar 2 tablets/wk as CNS-toxoplasmosis prophylaxis. Pentamidine loading dose is 200mg on 4 following days. maintanance dose is 200mg every 2 weeks. nebulized with Respigard II.Up to now. 63 patients have enroled in the study. 30 of them had PCP prior to pentamidine prophylaxis. Indication for inhalation prophylaxis was a T4 cell count <150/ l and AZT treatment.

Results: After a median observation time of 230 days. no patient under pentamidine developed PCP. 20 patients developing PCP during this period did not take pentamidine.

In the mentioned dosage. the agent was well tolerated. Systemic side effects were not observed. Because of heavy cough. 2 patients additionally needed a broncho-dilatator.

T.B.P.74 EFFICACITE' ET SURETE' DE LA PROPHYLAXIE AVEC PENTAMIDINE PAR AEROSOL DANS DES TOXICOMANES E.V. ITALIENS ATTEINTS DE SIDA, EN THERAPIE AVEC ZIDOVUDINE.

Caffa S., Giudici M.G., Vezzani F., Tumma A., Calonghi G.F.
Divis. Malattie Infettive, Arcispedale S.Maria Nuova, Reggio Emilia, Italy.

Objectif. Prophylaxie des premières crises et des récidives de PCP dans les toxicomanes atteints de SIDA.

Methode. Du mars 1988 jusqu'à aujourd'hui 15 patients toxicomanes italiens atteints de SIDA pratiquent la prophylaxie par aerosol de pentamidine en traitement ambulatoire, 6 patients ont commencé depuis plus de 12 mois, 1 patient est mort par une première crise de PCP au 9^{me} mois de prophylaxie, 8 parmi eux sont en traitement jusqu'à aujourd'hui depuis 2-6 mois, 1 patient a suspendu la prophylaxie parce qu'il est atteint d'une démence qui l'invalide. Tous les patients sont traités avec zidovudine au dosage de 600/1200 mg/die. 4 patients ont présenté avant la prophylaxie une episode de PCP. La pentamidine est administrée au dosage de 4 mg/kg/séance. Les séances sont bimensuel au cours du premier mois, en suite mensuel.

Conclusion. La PCP arrive dans plus de 60% des patients atteints de SIDA. Dans les patients sans prophylaxie on croit qu'elle arrive dans le 31-41% des patients dans les premières 24 semaines depuis la première crise de PCP. L'efficacité et la sureté de la Pentamidine par aerosol a été prouvée. Les concentrations pulmonaires sont plus grandes dans les poumons que dans le foie et les reins. Cette sorte de distribution empêche l'apparition des effets indésirables. Selon les premiers resultats de notre étude on n'a pas des effets indésirables; au contraire on a demontré de façon évidente une frequence plus pétite de PCP, soit des premiers épisodes, soit des rechutes dans les toxicomanes atteints de SIDA.

T.B.P.75 PROPHYLAXIS FOR PNEUMOCYSTIS CARINII PNEUMONIA (PCP) WITH AEROSOL PENTAMIDINE (AP) OR ORAL DAPSONE (OD) IN PATIENTS WITH AIDS OR SEVERE ARC.

Ramon A. Torres; Palermo B; Gregory C; Carlo C; Barlamides M; Chanin E et. al.
St. Vincent's Hospital, New York, N.Y. USA.

Objective: To evaluate and compare the efficacies and toxicities of AP and OD in the prophylaxis for PCP in patients with AIDS or severe ARC.

Methods: Since November 1987, 141 patients were enrolled and randomized to two treatment arms: AP (100mg every 2 weeks, delivered under supervision with a Pulmosonic nebulizer (DeVilbiss), MMAD 3.5 microns), or self-administered OD (100mg biweekly). Randomization was stratified into groups with prior PCP (n=76), no previous PCP (n=30), severe ARC (n=35). Relapse rate of historical controls is approximately 35% at 6 months.

Results: Mean length of follow-up was 26 weeks in AP arm and 20 weeks in OD arm. Of 118 patients evaluable, 65 were on AP and 53 on OD; 23 patients withdrew voluntarily, were lost to follow-up or expired prior to the first 6-month endpoint. Sixty percent of patients in each group were on AZT. Relapse rates were not significantly different for either drug in any group: Fisher's exact test: P>0.05

	Entire Group	s/p PCP	<1 mo.*	>1 mo.*	no PCP	ARC	AZT
Relapse Rate							
OD	6%	14%	12%	32%	0	0	10%
AP	9%	14%	5%	20%	0	8%	13%

*Interval from last episode PCP to onset of prophylaxis.

Transfusion requirements were similar in both groups and improvement in diffusion capacity occurred in 81% (AP) and 100% (OD) after 6 months. Bronchospasm occurred in 15% patients on AP, and rash requiring discontinuation of Rx, occurred in 7.5% of patients on OD.

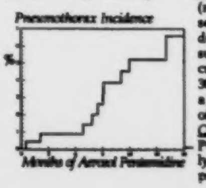
Conclusion: Oral Dapsone and aerosol Pentamidine are both effective prophylactic agents for PCP with similar rates of relapse and low rates of complications.

T.B.P.76 PNEUMOTHORAX IN PATIENTS RECEIVING AEROSOL PENTAMIDINE FOR *PNEUMOCYSTIS CARINII* PNEUMONIA PROPHYLAXIS.

Leoung, Gifford S.*; Wardlaw, L.*; Montgomery, A.B.**; Abrams,D.I.*; Feigal, D.W.*; and the SF County Community Consortium.
* Department of Medicine, San Francisco General Hospital, Univ. of California, SF; ** SUNY at Stonybrook, NY., U.S.A.

Objective: To determine the incidence of pneumothorax in patients on aerosol pentamidine for prophylaxis against *Pneumocystis carinii* pneumonia (PCP) in high risk HIV infected patients.

Methods: 408 patients were randomized to treatment with either 30mg q2w, 150mg q2w or 300mg q4w of aerosol pentam (AP) stratified into groups: prior PCP (PCP, n=256); Kaposi's Sarcoma (KS, n=56); or ARC and other AIDS diagnoses (OT, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.42 microns). Pneumothorax was prospectively documented as a component of study follow-up.



Results: Mean follow up in ongoing patients was 301 days (range 190-347). Thirteen episodes of pneumothorax were observed two of which were complications of invasive procedures. Three episodes were bilateral and seven patients had subsequent episodes. All but one patient had prior PCP. 4 occurred on the 30 mg q 2 week, 7 on 150 mg q 2 week and 1 on 300 mg q 4 week. Kaplan-Meier estimates of incidence showed a roughly linear trend in the group post PCP with an incidence of 1.4% at 6 months and 5.2% at 12 months.

Conclusion: Pneumothorax is a well recognized late sequelae of PCP. The lack of dose response and occurrence almost entirely in men post PCP suggests that aerosol pentamidine is not a primary factor.

T.B.P.77 AZT-AEROSOL PENTAMIDINE VS AZT ALONE IN LONG TERM AIDS SURVIVORS: A RETROSPECTIVE CASE-CONTROL SURVIVAL ANALYSIS.

SD Nightingale, SM Pounders, RS Ferguson, JD Jockusch. Parkland Memorial Hospital, Dallas, TX, USA.

40 of our 609 AIDS patients a) had PCP, b) survived >365 days after PCP, c) received AZT, and d) were started on aerosol pentamidine (AP), 300 mg q month, >365 days after PCP. Each was matched to a member of a control group of 41 patients who fit a), b), and c), but never received AP. Potential controls were all controls who had survived as many days as the case had survived before the case began AP; the control chosen was the one whose 1st PCP date was closest to that of the case. Case survival was evaluated from the day AP was begun. Control survival was calculated from the day after PCP its matched case was begun on AP.

We began AP in June 1988 and offered it to all AIDS patients thereafter. No other factor appeared to influence which of our patients became cases and which controls.

16 cases survived > controls, 4 controls survived > cases, and in 20 cases censored values made survival indeterminate (chi-square 14.4, p<.001). Actuarial survival on AP of the cases was 87% at 90 and 82% at 180 days vs 82% at 90 and 10% at 180 days for the controls (Wilcoxon p<.025,log rank p<.001).

Within the limits of the retrospective case-control method, the data suggest that AP can significantly prolong life in AIDS patients on AZT who have survived an episode of PCP by > 1 year.

T.B.P.78 DOUBLE-BLINDED RANDOMIZED TRIAL OF AEROSOL PENTAMIDINE FOR SECONDARY PROPHYLAXIS OF *PNEUMOCYSTIS CARINII* PNEUMONIA.

Leoung, Gifford S.*;Montgomery, A.B.**; McGinty, E.*; Feigal, D.W. *and the *LyphoMed* Consortium Investigators.
*University of California at San Francisco, USA.;** State University of New York at Stonybrook, USA.

Objective: To determine the safety and efficacy of aerosol pentamidine for *Pneumocystis carinii* pneumonia (PCP) prophylaxis in AIDS patient after first episode PCP.

Methods: 243 patients within 6 months after first episode PCP were randomized to 30mg or 150mg every 2 weeks of aerosol pentamidine (AP) via the Marquest Respigard II nebulizer (particle MMAD=1.42 microns) at 7 centers.

Results: 4 patients were disqualified for not meeting inclusion criteria, 2 for medication violations and 1 was never treated. After 9 months of enrollment with a mean follow up of 4.67 months, of the 236 PT on trial, 10 have had recurrent PCP with 2 deaths. 4 died from other causes, and 4 were too ill from other causes to continue. There were 2 episodes of pneumothorax; one associated with a PCP relapse. Systemic side effects are prospectively monitored at two month intervals. One patient discontinued therapy for thrombocytopenia.

Conclusions: Aerosol pentamidine is well tolerated and is associated with a low rate of early recurrence of PCP in high risk patients started shortly after first episode PCP. Systemic complications occur infrequently and extrapulmonary pneumocystosis has not been observed.

T.B.P.79

IS UPPER LUNG DEPOSITION OF NEBULISED PENTAMIDINE IMPROVED BY INHALATION LYING DOWN?

O'Doherty, Michael; Thomas, S.; Page, C.; Bradbeer, C.; Nunan, T. and Bateman, N.
St. Thomas' Hospital, London, UK.

Objective. To determine whether inhalation of pentamidine in the supine posture improves deposition in the upper zones.
Methods. Following salbutamol pre-treatment, 9 patients with AIDS inhaled 50 mg nebulised pentamidine mixed with 37 MBq 99mTc human serum albumin in the supine and sitting positions. To allow supine aerosol inhalation, 2 nebuliser systems, System 22 Mizer (S22M, Medicaid UK) and Respigard II (RII, Marquest) were modified by adding 150 ml tubing between nebuliser and mouthpiece. Pulmonary and non-pulmonary pentamidine deposition was measured when inhaled via the unmodified and modified apparatus by dynamic and static scanning using a gamma camera. For each patient a 133Xe equilibrium scan was obtained in both postures to correct upper to lower zone deposition ratios for relative lung volume.
Results. Absolute pulmonary deposition in mg (total [T] and right upper zone [RU]) is shown in the table for each nebuliser in each position:

Posture		S22M		RII	
		unmodified	modified	unmodified	modified
Sitting	[T]	2.78±0.42	1.35±0.23	1.53±0.31	1.87±0.16
	[RU]	0.38±0.27	0.16±0.04	0.18±0.04	0.22±0.03
Supine	[T]	–	1.49±0.27	–	2.36±0.35
	[RU]	–	0.19±0.04	–	0.29±0.05

In the sitting posture, modification of the systems reduced drug deposition using S22M (p<0.05). Total pulmonary deposition was not changed by lying down but the upper to lower zone ratio (corrected for lung volumes using the 133Xe counts) was increased.
Conclusion. Modification of S22M reduces its efficiency and is not recommended. The largest upper zone deposition was observed using an unmodified S22M in the sitting position. Using RII in the supine position increased upper zone deposition.

Diagnostic : Analyse de flux cytométrique et RCP
Diagnosis: Flow Cytometric Analysis and PCR

T.B.P.80

QUANTITATION OF HIV 1 PCR PRODUCTS BY SOLUTION HYBRIDIZATION WITH 125I-DNA PROBES.

Kuhns, M.*; McNamara, A.*; Bankowski, Matthew**; Kessler, H**
Landay, A.**; Falk, L.*, et al.
*Abbott Laboratories, North Chicago, IL. **Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL, U.S.A.

Objective: Polymerase chain reaction (PCR) amplified sequences are usually evaluated by spot or Southern blot hybridization or gel electrophoresis of PCR products after restriction enzyme treatment. A novel solution hybridization assay was used as a convenient, sensitive and quantitative method for detection of HIV-1 DNA and RNA following amplification by PCR.
Methods: The PCR product of a 680 base pair segment of the gag region was hybridized in solution with a high specific activity, single stranded 125I-DNA probe. The reaction was then applied to a gel column to separate hybrids from free probe in a single elution step. The hybridization assay itself has a sensitivity of $6x10^{-20}$ moles and is quantitative over 3.5 orders of magnitude in target concentration.
Results: The quantitative solution hybridization assay of DNA PCR products routinely detected 1-5 HIV-1 infected cells in $2.5X10^5$ uninfected cells. HIV DNA was detected in 28/28 anti-HIV positive patients (including asymptomatic, acute and AIDS stages) and in 0/18 negative controls. The frequency of HIV infected cells in AIDS patients ranged from fewer than 9 (4% of patients) to more than 400 (13% of patients) per 10^6 mononuclear cells.
Conclusion: These methods may be useful in monitoring DNA and RNA levels during anti-viral therapy.

T.B.P.81

DETECTION OF HIV-1 WITH POLYMERASE CHAIN REACTION IN RELATION TO RESULTS OF VIRUS CULTURE

Sönnerborg A*,**, Johansson B*, Strannegård Ö*.
* Central Microbiological Laboratory, Stockholm, Sweden, **Roslagstulls Hospital, Karolinska Institute, Stockholm, Sweden.

Objective. To compare the sensitivities of the polymerase chain reaction (PCR) and cultivation in detecting HIV-1.
Methods. PCR was performed using primers pairs with location 1551-1578 and1639-1665 in the gag gene and location 7801-7820 and 7923-7942 in the env gene on specimens from HIV-1 culture-positive or negative patients in different stages of infection.
Results. There was no complete agreement between the results of PCR and cultivation. Thus, some patients were repeatedly negative by PCR in spite of the fact that cultures yielded infectious virus. Conversely, PCR was positive in two subjects, who had symptoms indicative of HIV-infection, but were HIV-1 seronegative and culture negative. Specimens from HIV-1 seropositive persons, infected in Europe or USA, were more frequently positive by PCR than samples from individuals infected in Africa.
Conclusion. Detection by PCR of HIV-1 sequences in th gag and env region of the genome seems to be useful for the demonstration of HIV-1 infection in both seropositive and seronegative subjects. Because of possible strain differences the selection of primers is crucial for interpretation of results.

T.B.P.82

FAILURE OF THE POLYMERASE CHAIN REACTION (PCR) TO DETECT VIRAL HIV-1 DNA BY AMPLIFICATION OF A GAG SEGMENT IN HEMOPHILIACS WITH HIV ANTIBODIES.

Eyster, M. Elaine*, Goedert, J.** and Kumar, R.***
*Pennsylvania State University, Hershey, PA, **National Cancer Institute, Bethesda, MD, ***Frederick Cancer Institute, Frederick, MD, U.S.A.

Objective. To detect HIV DNA by PCR in multi-transfused hemophiliacs at high risk for HIV infection.
Method. A 115 base pair segment of the gag region of HIV was amplified by PCR and analysed by the rapid hybridisation method (probe-shift assay) described by Kumar et al (AIDS Res and Human Retrovirus, in press).
Results.

	PCR Pos.	PCR Neg.
HIV Antibody Pos. n=6	3*	3
HIV Antibody Neg. n=16	3	13
HIV antibody Seroconversion n=7		
Pre-conversion (5/7 tested)	3*	2
Post-conversion (6/7 tested)	3	3

*Two PCR pos. patients were also p24 antigen positive
Conclusion. PCR using a single probe and one set of gag region primers failed to detect HIV DNA in 50% of seropositive hemophiliacs. The use of short term culture of lymphocytes, additional probes, and multiple samples of cell lysates may improve detection. Definitive diagnosis of HIV infection in hemophiliacs may require a combination of immunological and molecular approaches. (Supported by NCI Contract NO1-CP-85649)

T.B.P.83

MULTIPARAMETRIC FLOW CYTOMETRIC ANALYSIS (LYMPHOCYTE P24-FCA) ALLOWS RAPID QUANTITATION OF ACTIVE HIV-1 INFECTION IN PERIPHERAL BLOOD CELLS

Ohlsson-Wilhelm, Betsy M.*; Cory, J.M.*; Kessler, H. A.**; Eyster, M. E.*; Rapp, F.*; and Landay, A.**
*The M. S. Hershey Medical Center, The Pennsylvania State Univ., Hershey, PA; and **Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL, USA.

Objective. To quantitate active HIV-1 infection rapidly (<24 hrs) in asymptomatic, HIV antibody positive, serum HIV p24 antigen negative homosexual men.
Methods. Lymphocyte p24-FCA was used to quantitate active HIV-1 infection in peripheral blood cells. The assay is based on binding of monoclonal antibody specific for p24 core protein; thus, only cells with actively replicating HIV are detected and results expressed as % p24 positive cells. Viral isolation was by standard coculture methods.
Results. Forty-one samples from 36 individuals were stratified by lymphocyte p24-FCA (range: <0.1-13.6%). (1) All (10/10) samples with lymphocyte p24-FCA >1.0% were positive by virus culture; only 2 of the remaining 31 samples were virus culture positive. (2) Neither monocyte nor granulocyte p24-FCA correlated with virus culture. (3) Lymphocyte p24-FCA did not correlate with % or number of CD4+ or CD8+ lymphocytes. (4) Serial samples from one individual showed an increase over 2 wk from 0.3% to 6.0% concomitant with conversion to virus culture positivity.
Conclusion. Lymphocyte p24-FCA allowed rapid (<24 hrs) monitoring of HIV-1 replication in seropositive, asymptomatic serum p24 antigen negative individuals and may be a valuable tool in monitoring antiretroviral therapy.
(Supported by USA NIH HLBI NO1-HB-67023 Project #221924 and AI25915).

T.B.P.84

USE OF FLOW CYTOMETRIC ANALYSIS (LYMPHOCYTE P24-FCA) TO EVALUATE ACTIVE INFECTION IN FEMALE SEXUAL PARTNERS AT HIGH RISK FOR HIV-1 INFECTION

Cory, J.M.; Ohlsson-Wilhelm, B. M.; Rapp, F. and Eyster, M.E.
M. S. Hershey Medical Center, The Pennsylvania State Univ., Hershey, PA, USA.

Objective. To monitor active HIV-1 infection rapidly (<24 hrs) in female sexual partners of multitransfused HIV-1 antibody positive hemophiliacs.
Methods. Multiparametric flow cytometry detected peripheral blood lymphocytes bearing HIV-1 major core protein p24 (lymphocyte p24-FCA). Thus, actively infected cells were quantitated and results expressed as %p24-positive; lymphocyte p24-FCA results >1.0% correlated with positive viral culture.
Results. (1) Of 15 samples from antibody(-) women, all had lymphocyte P24-FCA values ≤0.2%; partners of 4 of these women had AIDS. (2) Four antibody(+) women had lymphocyte p24-FCA values of 0.1, 0.2, 1.1 and 1.7%. (3) Serial samples 5 months apart (0.1%, 1.7%) were available for 1 woman, whose sexual partner died of AIDS. Further evidence of active infection within months of lymphocyte p24-FCA testing included the birth of a son who died of AIDS at <1 yr. Her CD4+ lymphocyte counts were stable in the 300-500/mm^3 range and she remained serum p24 antigen(-). (4) The lymphocyte p24-FCA result of 1.1% derived from another woman whose partner was persistently p24 antigen (+). Her CD4+ lymphocyte counts remained stable in the 200-300/mm^3 range and she remained serum p24 antigen(-).
Conclusions. Lymphocyte p24-FCA was used to assess active HIV-1 infection rapidly when other measures of infection remained stable.
(Supported by USA NIH HLBI, NO1-HB-67023 Project #221924, NCI NO1-CP-85649).

T.B.P.85 MONITORING THE ACCURACY OF THE TOTAL LYMPHOCYTE COUNT TO IMPROVE THE ABSOLUTE CD-4 COUNT

Anderson, Robert E.*; Hirschkorn, D.*; and Edmondson, S.**
*ViRx, Inc., San Francisco, CA, USA; **Sequoia-Turner Corporation, Mountain View, CA, USA.

Objective. To improve the accuracy of the total lymphocyte count, a key part of the absolute CD-4 lymphocyte count.
Methods. The white cell differential was determined using the Becton Dickinson FACSCAN with Simulset Software and Simultest Reagents (BD), microscopically on Wright-Geimsa stained smears (manual), and by electronic impedance on the Sequoia-Turner Cell Dyn 2000 (SQ) on a clinic-based HIV positive population.
Results. BD lymphocyte percentages were lowered when additional wash steps, vortex mixing, or aggressive aspiration (Asp) was used in cell preparation.

MEAN % LYMPH	SQ	BD	MANUAL	MAN-SQ (%)	MAN-BD (%)
Wash/Vortex/Asp	34.1	26.2	35.2	1.1 (3.1)	9.0 (25.6)
Vortex/Asp	36.2	33.8	39.2	3.0 (7.6)	5.4 (13.7)
Neither	37.7	37.4	39.4	1.7 (4.3)	2.0 (5.1)

Twenty-one room-temperature ACD whole blood specimens held for 0, 24 and 48 hours gave a mean percent lymphs of 36.8, 34.9 and 37.8 respectively, compared with 34.8 for EDTA.
Conclusion. With best technique, lymphocyte percentages from the FACSCAN, impedance, and manual methods are comparable. Monitoring all three methods insures good recovery from lymphocyte preparation methods. If processing delays occur, ACD is a superior anticoagulant for lymphocyte phenotyping.

T.B.P.86 WHERE LIES THE TRUTH ? METHODOLOGICAL INFLUENCE ON THE DETERMINATION OF CD4 AND CD8 LYMPHOCYTE SUBPOPULATIONS.

Fierz,W.; Vogt,M.; Lüthy,R. and Grob,P.; University Hospital, Zürich, Switzerland.

Objective. The number of CD4-positive lymphocytes in the peripheral blood of HIV-infected patients is an important prognostic parameter. However, the results of CD4 determinations from different laboratories are often not comparable. One of the reasons might be methodological differences.
Methods. We compared three different methods used to measure lymphocyte subpopulations:
- M1: Separation of mononuclear cells on a density gradient (Lymphoprep™, Nycomed), and staining with FITC-labeled monoclonal antibodies against CD4 and CD8 (Becton-Dickinson).
- M2: Whole blood was double-stained with FITC-labeled anti-CD4 and PE-labeled anti-CD8 monoclonal antibodies (Simultest™, B-D), and red cells were lysed with a one step lysing reagent (B-D).
- M3: Whole blood was double-stained with FITC-labeled anti-CD4 and PE-labeled anti-CD8 monoclonal antibodies (Coulter), and red cells were lysed with a three step lysing procedure on a Coulter Workstation™.

In all three methods the labeled cells were measured with a cytofluorometer (EPICS PROFILE™, Coulter). Results were compared using a linear regression model.
Results. M1 and M2 were compared with blood from 57 HIV-infected patients and from 29 healthy blood donors. CD4 values established with M2 were only 80% of the values determined with M1. Correlation coefficient (r) was 0.90. A retrospective comparison of the means of 500 consecutive CD4 determinations by M1 with 500 consecutive measurements by M2 in HIV-infected patients resulted as well in a similar difference. CD8 values correlated less well (r=0.79) but, in contrast to CD4, were about 10% higher if determined with M2 than with M1.
M2 and M3 were compared with blood from 36 HIV-infected patients and from 20 healthy blood donors. CD4 values measured with M3 were 25% higher than M2-determined values (r=0.95), which makes them comparable with M1-determined values. CD8 values, however, were again about 10% higher with M3 than with M2, moving them further apart from M1-determined values.
Conclusion. Methodological effects on CD4 (and CD8) values are substantial and have to be considered when comparing different studies. A simple explanation for the observed differences could not be found.

T.B.P.87 FLOW CYTOMETRIC METHODS FOR HIV SEROLOGY AND ANTIGEN QUANTITATION USING RECOMBINANT HIV ENVELOPE (ENV-9) PROTEIN

Campbell, D.*, Gentsch, Jon**, Papadopoulos, T.**, Janney, K.**, Rifat, S.*, Douglas, S.D.*
*University of Pennsylvania, Philadelphia, PA, USA, **E.I. Du Pont de Nemours & Co., Wilmington, DE, USA.

Objective: Flow cytometric (FC) methods were developed as potentially improved alternatives to enzyme-linked immunosorbent assays (ELISA) for the detection of HIV specific antibodies, and for the quantitation of HIV proteins.
Methods: Recombinant HIV envelope (ENV-9) protein was covalently coupled to 2.39um caboxylated polystyrene microspheres by carbodiimide mediated reactions and served as the solid phase antigen for both the FC serologic assay and for the FC antigen competition assay. The primary antibody probe for both assays was affinity-purified, biotin-conjugated goat anti-human IgG, while the fluorescence probe was FITC-avidin.
Results: The evaluation of forty four human sera by FC and ELISA revealed a high level of correlation (coefficient of correlation = 0.874) between FC mean channel fluorescence and ELISA endpoint titer. The FC antigen competition assay detected less than 50 picograms of recombinant HIV envelope protein.
Conclusion: The results of the FC HIV antibody detection assay and the FC HIV antigen competition assay demonstrate the potential usefulness of flow cytometry as an alternative method for the quantitation of HIV antibodies and detection of HIV antigens in infected cells.

T.B.P.88 IDENTIFICATION AND QUANTITATION OF HIV INFECTED CELLS IN PERIPHERAL BLOOD FROM AIDS PATIENTS BY FLOW CYTOMETRY

McSharry, James*; Echols, R.*; Stevens, R.** and Lehman, J.* *Albany Medical Center, Albany NY and **New York State Department of Health, Albany NY.

Objective: To develope a rapid method for quantitating the amount of HIV antigen in HIV seropositive patients. Methods: After obtaining informed consent, peripheral blood was taken from patients attending the AIDS Clinic at the Albany Medical Center. The mononuclear cells were isolated by centrifugation onto ficoll-hypaque, fixed in 90% methanol, incubated with monoclonal antibody to p24 antigen as the primary antibody and then with FITC - conjugated goat anti mouse IgG (Fab') as the secondary antibody. The cells were then treated with RNAse to remove RNA and then with propidium diiodide to determine the cell DNA profile. The stained cells were then analyzed by flow cytometry. Controls consisted of peripheral blood mononuclear cells obtained from HIV- seronegative patients with normal blood counts. Results: Flow cytometric analysis of treated mononuclear cells revealed that HIV-seronegative patients have essentially no p24 antigen- positive cells whereas HIV-seropositive patients had significant numbers of p24 antigen- positive cells. The % positive cells correlated with the CDC criteria for clinical staging of the disease in that patients in stage II had fewer p24 positive cells than those in stage III and stage IV. Furthermore, in all cases tested, and at each stage of the disease, the p24 antigen-positive cell was of the monocyte/macrophage lineage on the basis of size as determined by light scatter and adherence to fetal bovine serum coated petrie dishes. Conclusion: These results suggest that flow cytometry can be used as a rapid, quantitative system to determine the antigen status of HIV-seropositive patients which may be useful as an indicator of disease progression.

T.B.P.89 STATISTICAL ANALYSIS OF FLOW CYTOMETRIC DATA: A NON-PARAMETRIC APPROACH

Lacouture, Yves; Cardno, T; Tsoukas, C. Flow Cytometry Laboratory, Montreal General Hospital, Montreal, Quebec, Canada.

Objective: To evaluate non-parametric approaches to the statistical analysis of T cell subsets. The enumeration of CD4 positive lymphocytes is currently considered essential for monitoring the course of HIV infection. Lymphocyte subsets are furthermore dependent variables used to enroll patients in clinical trials and to evaluate outcomes of treatments. Despite the practical importance placed on quantitating T cell subsets little attention has so far been placed on the statistical methods used for analysis.
Methods: Flow cytometric data was obtained on 100 HIV seronegative volunteers and 200 HIV seropositive patients with varying clinical stages of HIV disease. Dual staining of cells with monoclonal reagents conjugated to either fluorescein or phycoerythrin were used to identify T helper, suppressor, inducer, cytotoxic, NK and activated cells.
Results: The observed distribution of flow cytometric data did not follow a Gaussian probability function and traditional parametric methods were inadequate for analysis. Percentile ranges and absolute median deviation were used instead of standard deviation as dispersion indices; median and mode instead of mean as localization indices. These statistical estimators provided a cleaner view of the skewed distribution of the data (presented using exemplar distributions). A non-parametric test, the Mann-Witney U-test, was noted to be useful for hypothesis testing.
Conclusion: Although statistically less powerful the non-parametric hypothesis testing leads to improved reliability in flow cytometric data analysis.

Diagnostic : Détection des antigènes
Diagnosis: Antigen Detection

T.B.P.90 ANTIGENEMIE VIH AU COURS DE LA PRIMOINFECTION

Schiavini D.*, Puel Jacqueline*, Averous S.**, Bazex J.**
*Laboratoire de Virologie, CHU Purpan, Toulouse, FRANCE
**Service de Dermatologie, CH La Grave, Toulouse, FRANCE.

Objectifs. Etudier la précocité de l'antigénémie lors de la primoinfection Il a été écrit qu'elle pouvait précéder la séroconversion de 34 mois(Ranki A. Lancet 87;ii:589) ou de quelques mois (Goudsmit J.Lancet 87;i:317- Allain JP Lancet 86;ii:1233) mais ces résultats sont controversés (Courouce AM,Lancet 87;ii:1025).
Méthodes.
Détection, titrage de l'antigénémie p24 (technique Abbott) et confirmation par neutralisation réalisée sur des sérums recueillis 2 à 14 mois (moyenne : 9 mois) avant la séroconversion observée chez 19 patients homosexuels.
Résultats.
-Aucune antigénémie n'a jamais été détectée avant la séroconversion, toutefois nous n'avons pas disposé de sérum dans le mois précédant la séroconversion.
-Au moment de la séroconversion une antigénémie a été observée chez 15 sujets Elle a disparue en 1 mois dans 11 cas, en 3 mois dans 4 cas.
-Une antigénémie a été observée chez un patient un mois seulement après la séroconversion, elle a disparu en 3 mois.
Conclusion. L'antigénémie n'est donc pas un marqueur sérologique précoce et fiable de l'infection VIH; accompagnant la séroconversion, elle est fugace, inconstante, parfois retardée.

T.B.P.91

PRODUCTION AND CHARACTERIZATION OF HUMAN IMMUNODEFICIENCY VIRUS ANTIGENIC DETERMINANTS AND THEIR USE IN DIAGNOSTICS OF AIDS

S.Arsenian, O.Voloshin*, A.Shevalier*, M.Michailov*, I.Nikolaeva**, V.Rostapshov, and E.Sverdlov
M.M.Shemiakin Inst.Bioorg.Chem., Acad.Sci.USSR; *RPA Biotechnology Minmedbioprom; **Inst.Immunol. Minzdrav; Moscow, USSR.

With a view to have immunodiagnostic kits for detection of AIDS in humans we obtained bacterial strains expressing recombinant proteins which include amino acid sequences of the main antigenic determinants of human immunodeficiency viruses (HIV). The spectrum of expressed antigenic determinants overlaps their variability among different HIV isolates. The content of the expressed recombinant protein in cell lysates amounts to 30-50% that enables one to use the synthesized antigens for immunological reactions without further purification. Using a large panel of sera taken from AIDS patients interaction of the recombinant antigens with anti-HIV antibodies was statistically analysed.

T.B.P.92

SENSITIVITY OF FIVE COMMERCIAL HIV-ANTIGEN DETECTION METHODS.

Casado C., Varela J.M., Vallhonrat E., Garcia Saiz A., Najera R.
Instituto de Salud Carlos III, Madrid, Spain.

OBJETIVES.- To present data about the perfomance of commercial -- kits for HIV - antigen detection by testing with a panel of sera and infected cell-culture supernatants.

METHODS.- To build our evaluation panel we have selected antibody positive sera which didn't show any reactivity for anti-CORE antibodies by the CIA -RA (ENVACOR HIV-1, Abbott) method.

The chance of a serum to be antigen reactive is higher than if it was entCORE positive.

The antigen detection methods used in this work have been: Abbott HTLV-III Antigen EIA, Du Pont p24 CORE Antigen ELISA, ELAVIA AgI (Diagnostics Pasteur), Coulter HIV Ag assay and Vironostika HIV Antigen (Organon).

The sensitivity study was completed by setting up the end-point dilution in cell-culture supernatants for each method.

RESULTS.- We have found relevant differences of sensitivity by testing the sera panel and the dilutions.

CONCLUSIONS.- We think that our study may give information about the antigen detection ability of five commercial Kits. This could be an additional approach in order to decide which HIV antigen detection kit might be selected.

T.B.P.93

USE OF TRITON-X IN THE HIV ANTIGEN ASSAY TO ASSESS THE PRESENCE OF INFECTIVE HIV.

James L. Stewart*; Ketchum, S.*; Coombs, R.W.**; and Allain, J.P.*
*Abbott Laboratories, N Chicago IL and **University of Washington, Seattle WA, USA.

Objective. Compare the performance and significance of the current HIV antigen (HIV Ag) capture assay to a modification using Triton X-100 to disrupt potential whole viral particles in the samples.
Methods. Serum plasma samples were tested neat or in the presence of 0.5% Triton X-100 according to previously described methods (Lancet 1986, 2, 1233). In some cases, results were compared to the capacity of plasma to infect stimulated normal peripheral blood lymphocytes.
Results. In 36 samples from 7 patients collected at close interval pre and post seroconversion, 11 samples were HIV Ag + in the presence and 7 in the absence of Triton. All 5 HIV Ag + samples tested were infectious in culture while 3 of 10 HIV Ag- were infectious. In 140 seropositive samples (49 asympcomatic, 41 ARC and 50 AIDS) 52 and 47 were HIV Ag + in the presence or absence of Triton, respectively. This additional sensitivity seemed to correspond to the disruption of whole virions since in 18 samples where HIV plasma culture was performed, all 15 positive culture samples were positive with the Triton treated HIV Ag assay.
Conclusion. The treatment of samples for HIV Ag testing with Triton X-100 inactivated infective HIV and improved the assay sensitivity by increasing the amount of antigen available to capture. The good correlation betweer culture infective plasma and positive result of Triton treated HIV Ag as suggested that the presence of HIV Ag reflected active viral replicatio

T.B.P.94

EVALUATION OF TWO HIV ANTIGEN ENZYME IMMUNO ASSAYS ON EUROPEAN AND AFRICAN SERA

Vercauteren, Gaby, van der Groen, G., Piot, P.
Institute of Tropical Medicine, Antwerp, Belgium.

Objective: To compare the performance of two HIV antigen capturing enzyme immunoassays (EIA) (Abbott and Innogenetics for the detection of free HIV antigen in human serum).
Methods: Two hundred seventy anti-HIV positive (51 African, 219 European), and 42 anti HIV negative sera were screened with the HTLV III antigen EIA (Abbott) and the Innotest HIV antigen (Innogenetics distributed by Organon Teknika and Wellcome). Reactive samples were tested for confirmation with a neutralisation assay of the respective manufacturers.
Results: Initial screening yielded 49 sera reactive in the Abbott and 66 sera reactive in the Inno test. Fourty-one samples were reactive in both assays. Eighty-eight percent (36/41) of the samples reactive in both assays were confirmed with the Abbott test while 98 percent (40/41) were confirmed with the Inno-test. Three out of the 8 excusively Abbott reactive samples and 13 out of the 25 exclusively Innogenetics reactive sera were confirmed. Antibodies to p24 (Abbott HIV1 anti core EIA), were absent or of very low level in the discrepant antigen reactive sera. All of these patients, except one, which was stage 1, were classified as having ARC or AIDS. We therefore presume that regardless the assay the confirmed samples are true HIV antigen positive sera. The HIV antigen seropositivity in the African and European sera was respectively 5.9 % (3/51) and 24.2 % (53/219) (p = 0.006). Among the African sera 64.7 % had ep24 levels higher than ratio 10.0 (OD cut off/OD samples) while this was only the case in 17.8 % of the European sera ($p < 10^{-6}$).
Conclusion: We obtained more HIV antigen confirmed positive results with the Innotest HIV antigen EIA. This observation can perhaps be explained by a higher sensitivity of this test or by its capability to capture a wider range of HIV antigens. Our results confirm that HIV antibody positive sera from African patients contain less often free HIV antigen, possibly because of a higher production of anti p24 antibody.

T.B.P.95

LACK OF CORRELATION OF P24 ANTIGENEMIA WITH CLINICAL STATUS OR PERIPHERAL BLOOD T4 LYMPHOCYTES (PBT4) IN WOMEN WITH HIV INFECTION.

Charles CJ Carpenter. Mayer KH. McCrow L. Danforth S. Brown University Medical Center. Providence. RI USA.

Objective. To determine the relation between p24 antigenemia. PBT4. and clinical status in women with HIV infection. Methods. 24 HIV-seropositive women were periodically evaluated for 24 months. with monitoring of clinical status and PBT4. and monthly determinations of serum p24 antigen (p24Ag) in individuals with antigenemia. Results. In 14 asymptomatic (AS) women (mean age 27). mean PBT4 count was 787 ± 127 (SEM). In 5 women (mean age 34) with AIDS-related complex (ARC). mean PBT4 was 191 ± 60 (SEM). In 5 women (mean age 35) with AIDS. mean PBT4 was 60 ± 24 (SEM). 3 individuals (1 AS. 1 ARC. 1 AIDS) had persistent p24 antigenemia. In the AS individual. mean p24Ag was 63 pg/ul: mean PBT4 was 862. In the person with ARC. mean p24Ag was 130 pg/ul: mean PBT4 was 194. In the women with AIDS. mean p24Ag was 78 pg/ul: mean PBT4 was 170. Each antigenemic women has been clinically stable during the past 12 months. The individual with AIDS had one brief hospitalization for perineal herpes: the other two antigenemic women had no limitation of activities of daily living. Conclusions. These data confirm a highly significant correlation between PBT4 and clinical status. but fail to show correlation between persistent p24 antigenemia and either clinical status or PBT4 counts in these 24 HIV-positive women.

T.B.P.96

CORRELATION OF HIV CORE ANTIGEN, ANTIBODY AND IMMUNE COMPLEX LEVELS IN SERA OF HIV-INFECTED INDIVIDUALS

Ujhelyi, E.*, Lange, J.**, Goudsmit, J.**, Salavecz, V.*, Füst, G.*, Hollán, S.R.* et al.
*Natl.Inst.Haematol.Blood Transfusion, Budapest, Hungary; and **Dept. Virol., Acad. Med. Center, Univ. Amsterdam, Amsterdam, The Netherlands.

Objectives. To measure the relationship between the presence of HIV core-anti-core (core IC) and env-anti-env (env IC) immune complexes on the one hand, and the amounts of free core antigen, free core and env antibodies on the other. Methods. Levels of core IC and env IC were measured by the method of Ujhelyi et al (AIDS,1,161,1987). HIV antigen was detected by a sandwich ELISA assay, free core and env antibodies were measured by the ENVACOR test. Sera of HIV-infected individuals containing core IC and/or env IC (18/40) were selected for the study. Results. Free core antigen was found in 8/18 samples. Free env antibodies were present in all sera tested, free core antibodies were found in 12 samples. Core IC and env IC were detected in 11 and 14 samples, resp., in 9 sera both types of complexes could be detected. The presence of core IC were associated with a decreased titre of free core antibodies (13.3±25.5 vs 110.0±32.3, p=0.01) and increased incidence (7/11 vs 1/7, p=0.05) of free core antigen. Conclusion. Formation of core-anti-core immune complexes in HIV-infected individuals is due to the increase of the antigen load and binding of antigen to the specific antibody.

T.B.P.97

DETECTION OF HIV-1 P24 ANTIGEN IN SERUM WITH A NEW MONOCLONAL EIA

Dascal,Andre*;Rene,P.**,Spira,B.*,Chan-Thim,J.*,Mendelson,J.*, Wainberg,M.* et al.*SMBD-Jewish General Hospital and **Royal Victoria Hospital, McGill University, Montreal, Canada.

Objective. To evaluate a new 4 hour EIA for the detection of HIV-1 p24 antigen in serum samples.
Methods. We compared a new monoclonal antigen enzyme-immunoassay (EIA) from Dupont (DP) with a widely used commercially available EIA from Abbott (AB) for the detection of HIV-1 p24 antigen in 203 sera: 99 sera from confirmed HIV-1 antibody seropositive patients (HIV+), 28 from HIV-1 antibody seronegative patients with autoimmune disease (AUT), and 76 from HIV-1 antibody seronegative normal patients (NL). Sera were processed as recommended by the respective manufacturers except that they were run in single wells because of limited sera quantities. Two cut off values for the new EIA,DP, were evaluated: a) 0.1 + mean optical density (O.D.) of control negative sera (CNS) supplied in the kit, and b) 0.08 + mean O.D. of CNS. Confirmatory tests were run on AUT and NL samples that were either DP or AB positive.
Results. Analyzing the data with DP cut off O.D. values of 0.1+ mean O.D. of CNS 19% (19/99) of HIV+ were positive by both DP and AB, 4% (4/99) were positive by DP and not AB, whereas 4% (4/99) were positive by AB but not DP. 4 and 1 of AUT were falsely positive by DP and AB respectively. Of the 76 NL sera 2 were falsely positive by DP and 4 by AB. However using a DP cut off value of 0.08+ mean O.D. of CNS resulted in 20% (20/99) of HIV+ being positive by both DP and AB, 3 being positive by AB only and 8 by DP only.Results of AUT and NL groups didn't change. DP O.D. values tended to be higher than AB.
Conclusion. There was no statistically significant difference in sensitivity and specificity of DP and AB when sera were tested. However, DP in this study tended to have higher O.D. values than AB and at a O.D. cut off of 0.08 + mean CNS DP tended to pick up more positives in the HIV+ group. Further studies with this short (4 hr.) EIA are warranted.

T.B.P.99

Specificity of HIV antigen capture assays

Ivo-dos-Santos, J.; Couto-Fernandez, J.C. and Galvão-Castro, B. Department of Immunology, Oswaldo Cruz Foundation, Ministry of Health, Who Collaborating Centre, Rio de Janeiro, Rio de Janeiro, Brazil.

Objective: To evaluate the specificity of two HIV antigen capture assays with antigens obtained from several pathogens.
Methods: The Abbott HTLV-III antigen EIA and Organon Vironostika HIV antigen Micro-ELISA systems were tested with antigens obtained from: a) Viruses: dengue, hepatitis A, B and delta, herpes simplex type 2, HIV-1, HIV-2, HTLV-1, measles and yellow fever; b) Bacteria: Salmonella typhi and Staphylococcus aureus; c) Fungi: Aspergillus fumigatus, Histoplasma capsulatum, Paracoccidioides brasiliensis and Candida albicans; d) Protozoans: Plasmodium falciparum, Trypanosoma cruzi and Toxoplasma gondii; and e) Helminths: Schistosoma mansoni.
Results: All but HIV-1 and HIV-2 were negative (below cut off values). In the Organon assay (cut off = 0.063) the mean value of optical density of HIV-1 and HIV-2 were 1.638 and 0.434 respectively. In the Abbott assay (cut off = 0.136) the mean values were 1.537 for HIV-1 and 0.447 for HIV-2.
Conclusions: The results suggest that although the assays tested are very specific for immunodeficiency viruses, not reacting with pathogens associated with several endemic diseases, they do not definitively discriminate between HIV-1 and HIV-2.

This work was supported by Fundação Banco do Brasil.

T.B.P.101

COMPARISON OF ASSAYS FOR THE DETECTION OF HIV-I ANTIGEN

W.A. Meyer III*, Amy R. Atkinson*, L. Kahl**, and D. Senn**

Maryland Medical Laboratory (MML), Baltimore, Maryland, USA and Electro-Nucleonics, Inc. (ENI), Columbia, Maryland, U.S.A.

Objectives: To evaluate the sensitivity of 4 commerically available assays for the detection of HIV-I antigen in HIV-I antibody positive blood samples.
Methods: Sera or plasma were received by MML as part of research protocols for HIV-I antigen testing. Samples were first tested with the Abbott antigen assay. Samples which were repeatedly reactive in the Abbott test and confirmed by neutralization were considered positive for HIV-I antigen. All samples (Abbott positive or negative) were subsequently tested with the ENI, Dupont, and Coulter assays for HIV-I antigen. Testing was performed at MML with strict adherence to the instructions in the package insert for each kit. Abbott antigen negative samples, which were repeatedly reactive in either the ENI, DuPont, or Coulter kits, were confirmed as true positives using the neutralization reagent from the appropriate manufacturer. The sensitivity of the kits was ranked according to the number of confirmed positive samples. Samples which were repeatedly reactive but could not be neutralized were considered to be false positives.
Results: The rank order of the sensitivity of the assays was ENI (overnight) ≫ Coulter ~ DuPont (overnight) ~ ENI (short) ≫ Abbott (overnight).
Conclusions: There was a difference in the ability of commerically available tests to detect HIV-I antigen in HIV-I antibody positive blood samples. The most sensitive test appears to be the Electro-Nucleonics assay (overnight format).

T.B.P.98

SPECIFICITY OF HIV-1 P24 ANTIGEN CAPTURE ASSAY AS VIRAL GROWTH DETERMINANT IN TISSUE CULTURE FLUIDS (TCF).

Homayoon Farzadegan, K. Qatsha, P. Gupta, C. Grovit, C. Rinaldo, A. Saah: The Multicenter AIDS Cohort Study (MACS), NIH, Bethesda, MD, USA.

OBJECTIVE: To determine whether neutralization (blocking) assay for specificity of HIV-1 P24 antigen capture assay in TCF is required.
METHOD: HIV-1 isolation from blood cells of homosexual men were carried out in two MACS virology laboratories. Cocultivation of patients PBMC's with normal PHA-P stimulated lymphocytes were monitored for HIV-1 growth by P24 antigen capture assays for four weeks. Two different commercial Kits (Abbott and Dupont) were used. A standard curve was used to determine the concentrations (conc.) of P24 in pg/ml. All samples reactive at two timepoints were re-tested in the presence and absence of anti-P24 to confirm the specificity of the assay. Various conc. of P24 were analyzed for specificity of antigen capture reactions and percent neutralization.
RESULTS:

P24 Conc.	< 200 pg/ml		200 - 600 pg/ml		> 600 pg/ml	
	* N/Total	**(X̄%N)	* N/Total	**(X̄%N)	*N/Total	**(X̄%N)
Center A	26/26	100%	11/11	81%	14/14	93%
Center B	30/30	95%	30/30	100%	30/30	94%

* N/Total = Neutralized/Total, **(X̄%N) = Mean Percent Neutralization

All of the 141 TCF samples reactive for the second timepoint neutralized. Percent neutralization was not notably different at various conc. of P24.
CONCLUSION: HIV-1 P24 antigen capture assay does not need to be neutralized when performed on the second reactive sample of TCF.

T.B.P.100

HIV-ANTIGENS: PREVALENCE AND CORRELATION WITH CLINICAL EVOLUTION IN AN HIV-INFECTED FLORENTINE COHORT

Di Pietro, Massimo*; Mazzotta, F.*; Milo, D.*; Paci, P.*; Bartolozzi, D.*; Colao, M.G.**; De Majo, E.**.
*Div. Malattie Infettive and **Lab. Batteriologia; Ospedale Careggi USL 10/D, Firenze, Italia.

Aim: Research and follow-up of HIV-antigens positivity (Ag+) in HIV-infected subjects with respect to their clinical stage.
Methods: 206 HIV-infected patients (pts.) where screened for HIV-antigens with ABBOTT kit (included a confirmatory test by neutralisation).In 124 pts., all without AZT treatment during follow-up, we repeated the test every 4-6 months. At this moment the mean period of observation is 19 months (range 6-36). 10 more Ag+ AZT recipients were tested every 30 days for HIV-Ag while being treated.
Results: The Ag+ pts. were 1 on 51 in group II (CDC '87), 9 on 64 in group III; 13 on 38 in group IV no AIDS and 35 on 48 AIDS pts. (IVC1 & IVD). In our open cohort we enrolled: 10 pts. of group IVC1; 23 of IVC2/IVA; 53 of III and 38 of II. All the AIDS pts. have been constantly found Ag+. At this moment in other pts. we observed an evolution of the disease in 38 pts., 17 of whom were Ag+, while only 9 on 82 stationary pts. were Ag+ (p<0,001).We refer also on the level of HIV-Ag during the AZT tretment.

These data, thought supporting the specifity of the test, do not warrent its sensitivity as tool for monitoring disease progression.

T.B.P.102

COMPARISON OF THE ORGANON TEKNIKA CORPORATION HIV ANTIGEN ASSAY WITH SIX COMMERCIALLY AVAILABLE HIV ANTIGEN TEST KITS.

Lockwood, Don, Youngber, P., Hyman, J., Holody, T.; Berman, B.*; and Tondreau, S.**. Organon Teknika Corporation, Durham, NC, USA, *Bionetics Research, Inc., Rockville, MD, USA, **Bionetics Research, Inc., Kensington, MD, USA.

Objective. The Organon Teknika Corporation (OTC) HIV Antigen Assay is a monoclonal antibody based, direct sandwich enzyme immunoassay for detection of HIV-1 p24 core antigen. The test utilizes 100 ul reaction volumes and can be performed in 2.5 hours. The ability of the OTC test to detect HIV-1 p24 antigen and crossreact with HIV-2 antigen was compared to that of 6 HIV antigen assays available as research only tests.
Methods. Sensitivity panels were prepared from the DuPont HIV-1 p24 standard, HIV-2 lysate, and 3 clinical samples. Also, 10 positive clinical samples, 8 borderline reactive in the OTC assay, were included as undiluted test samples. All reactive samples were confirmed positive by neutralization. The commercially available tests included 4 that utilize overnight incubation and 2 with total incubation times of 3 and 2.5 hours.
Results. The OTC assay and 3 commercial tests detected 10 pg/ml HIV-1 p24. Two tests detected only 40 pg/ml HIV-1 antigen. The OTC HIV Antigen Assay was the most sensitive for HIV-2, detecting 0.5 ng/ml viral lysate. The commercial tests ranged from a detection limit of 2 to >512 ng/ml HIV-2 lysate. Of 11 members in the clinical sample sensitivity panel, OTC detected 8 samples while the other tests detected from 1 to 7 members. One overnight commercial test detected 8 of the 10 OTC positive clinical samples while the other tests detected only 4 or less.
Conclusion. These results indicate the OTC assay, the most rapid, non-amplified monoclonal based HIV Antigen test developed to date, has equal or greater sensitivity to HIV-1 and HIV-2 than current commercially available kits.

T.B.P.103 Prognostic Significance of HIV-antigenaemia in AIDS.

Lars L.S. Teglbjærg and Court Pedersen
Dept. of Infectious Diseases 144, DK-2650 Hvidovre Hospital, Denmark.

Objective: To assess the the correlation of HIV-antigenaemia with mortality in AIDS patients.

Materials & methods: Serum samples from the first 157 AIDS patients at Hvidovre Hospital were analyzed using a HIV recombinant antigen enzyme immunoassay (Abbott Laboratories).

Results: One-hundred fifty-one patients had available serum samples from the time of the AIDS diagnosis. Of these 84 (56%) were HIV-antigen positive and 67 (44%) were antigen negative.

Among the HIV-antigen positive AIDS patients, there was a significant correlation between high HIV-antigen level and short survival. No significant difference was found in overall mortality and length of survival between the group of HIV-antigen positive and the group of HIV-antigen negative. These findings were due to the mortality distribution in the group of HIV-antigen negative patients. This distribution showed two peaks; one shortly after diagnosis and one approx. 1 year after the time of diagnosis.

Conclusion: HIV-antigen level in AIDS patients at the time of diagnosis has a prognostic value in patients with detectable HIV-antigenaemia. The mere presence of detectable HIV-antigen at the time of diagnosisis is not a prognostic marker.

Diagnostic : Infection par le VIH-2
Diagnosis: HIV-2 Infection

T.B.P.104 EVALUATION OF A SYNTHETIC PEPTIDE EIA FOR DETECTION OF ANTIBODIES TO HIV-1 and HIV-2

Thorstensson, Rigmor*; Mhalu, F.**; Andreasson, P-Å.***, and Biberfeld G* et al.
*National Bacteriological Laboratory, Stockholm, Sweden, **Muhimbili Medical Centre, Dar es Salaam, Tanzania, ***National Public Health Laboratory, Bissau, Guinea Bissau.

Objective. To evaluate a synthetic peptide EIA(Enzygnost Anti-HIV 1+2) for detection of antibodies to HIV-1 and HIV-2 by use of a 4 peptide mixture (2 from HIV-1 gp41, 1 from HIV-1 gp120 and 1 from HIV-2 gp41) as antigen and to compare the assay with Abbott's recombinant HIV-1 EIA and/or Pasteur's Elavia 2 (reference methods).

Results. 202 HIV-1 positive Swedish sera, 75 HIV-1 positive high risk sera from Tanzania and 108 HIV-2 positive sera from Guinea Bissau were all reactive in Enzygnost as well as in the reference methods (sensitivity 100%). Among 77 sera containing autoantibodies and 999 other HIV-negative sera from Sweden 2 sera were repeatedly reactive in Enzygnost and Abbott resp, (specificity 99.8%). Of 48 sera which had been falsely reactive in Abbott only 1 was repeatedly reactive in Enzygnost. Analysis of 14 sera from 5 individuals with early HIV infections showed that the reactivity in Enzygnost-anti-HIV 1+2 was higher than in in the Abbott recombinant EIA. Thus Enzygnost may detect some seroconversions earlier than the Abbott assay. This may be due to stronger antibody binding, as could be demonstrated by comparative testing of serially diluted anti-HIV positive sera. Analysis of 503 Tanzanian blood donor sera of which 40 were positive showed 100% sensitivity in Enzygnost. Establishment of cut off values for the African sera and further specificity tests remain to be done but so far the specificity seems to be above 95%.

Conclusion. The sensitivity of Enzygnost anti-HIV 1+2 was 100% for detection of antibodies to both HIV-1 and HIV-2.

T.B.P.105 APTITUDE D' UN TEST RAPIDE POUR HIV ET DE TESTS D' AGGLUTINATION A DETECTER DES ANTICORPS ANTI-HIV2 AU SENEGAL.

Mboup Souleymane*, Sankalé J.L.*, Kabeya C.M**, Diakhaté L.***, Thiam D.***, Mitchell S.****
*Bactério-Virologie/Université de Dakar **Projet SIDA/Kinshasa ***Centre National de Transfusion Sanguine/Dakar ****AIDSTECH/Family Health International, USA.

Objectif: Evaluer l'efficacité de tests d'immunofixation sur membrane (DOT-Blot) et d'agglutination conçus pour HIV1 au Sénégal, pays où circule à la fois HIV1 et HIV2.

Méthode: 2000 prélèvements sanguins de donneurs de sang, de personnes à haut risque, et de patients suspects de SIDA ont été testés par HIVCHEK (Dupont, USA). Tous les positifs, les indéterminés, et 10% des négatifs ont été testés en double en RETROCELL (Abbott) et en SERODIA-HIV (Fujirebio, Japon). Ces tests ont été réalisés sur le terrain dans 6 centres au Sénégal. Tous les sérums ont aussi été testés par ELISA en HIV1 et HIV2, puis les positifs par Western-Blot HIV1 et HIV2.

Résultats: Cette étude est en cours et sera achevée en janvier. La sensibilité pour la détection des HIV2 sera étudiée ainsi que la spécificité des 3 tests.

Les résultats provisoires montrent une bonne répétabilité des tests:

Nbre de serums	Hivchek +	Hivchek répété +	Retrocell + Serodia +	Retrocell - Serodia -	Retrocell douteux Serodia +
1005	31	31	27	2	2

Conclusion: Les nouveaux tests de dépistage du HIV qui sont simples, rapides, et économiques et ne nécessitent pas un équipement spécial vont pouvoir faciliter grandement le dépistage dans les pays en voie de développement. Cependant, il est urgent que ces tests comprennent des antigènes multiples.

T.B.P.106 HIV INFECTION IN CANADA

P. Neumann*, M. V. O'Shaughnessy*, D. Lepine*, I. D'Souza**, C. Major***, B. McLaughlin***, *Federal Centre for AIDS, Ottawa; **Toronto; ***Laboratory Services Branch, Ontario Ministry of Health, Toronto, ON, Canada.

Infection with the retrolentivirus HIV-2 is common in specific regions of West Africa. Infection by HIV-2 in North America had been limited to a single case, a patient from New Jersey. We now describe the first three cases of HIV-2 infection in Canada. All were from an endemic area in West Africa and two were asymptomatic. Sera from all 3 were positive on HIV-1 EIA screen tests (Dupont and Genetic Systems) but displayed a conspicuous absence of antibody to the gp41 transmembrane protein of HIV-1. HIV-2 specific immunoblot demonstrated reactivity to the p36 (env) and p25 (gag) determinants. Serum from both patients reacted strongly with HIV-2 infected cells but not uninfected controls or HIV-1 infected cells by immunofluorescence. Identification of an HIV-2 positive person from an endemic area is not surprising but does require that a continued vigilance be maintained for the spread of this virus into the Canadian population.

T.B.P.107 HTLV-I ANTIBODY PREVALENCE IN PATIENT POPULATIONS IN ZAIRE: ANALYSIS OF WESTERN BLOT (WB) PATTERNS

Brown, Christopher*, Nzila N.*; Atikala, L; Behets, F.*; Ryder, R.*; Quinn, T.C.**, et al.; *Projet SIDA, Kinshasa, Zaire; **NIAID, NIH, Bethesda, Md, U.S.A.

Objective. To determine the prevalence of antibody to HTLV-I and the distribution of WB reactivity in different Zairian populations.

Methods. 1064 Zairian sera were tested by HTLV-I ELISA (DuPont) and repeatedly reactive samples were tested by HTLV-I specific WB (DuPont). A positive WB had gag (p19, p24) and env (gp 46), reactivity or had at least three specific antigen bands including both p19 and p24. An indeterminate (IND) result did not meet the above criteria but had reactivity to at least p19 or p24, with or without other bands present. RIPA analysis of sera will be performed on ELISA reactive sera without WB env reactivity.

Results: Sample	HTLV-I (+) WB		HTLV-I (IND) WB	
All sera (n=1063)	65	(6.0%)	68	(6.4%)
All Prostitutes (810)	49	(6.9%)	37	(4.6%)
HIV (+) Prostitutes (288)	20	(6.9%)	11	(3.8%)
HIV (-) Prostitutes (515)	25	(4.8%)	24	(4.7%)
HIV (-) Factory workers (125)	6	(4.8%)	13	(10.0%)
HIV (-) Rural workers (88)	74	(8.0%)	9	(10.2%)
HIV (-) TB Patients (90)	3	(3.3%)	7	(7.8%)

Gag plus env bands were found in 44 (4.1%) of 1063 sera. p19 and p24 bands were present in 67 (6.3%) of 1063 sera.

Conclusion. A relatively high prevalence of HTLV-I WB reactivity was observed in several Zairian populations ranging from 3.3% to 6.9%. In this study HTLV-I reactivity did not correlate with HIV-I serostatus.

T.B.P.108 HIV-1 AND HTLV-1 PREVALENCE IN AFRICAN AND EUROPEAN POPULATIONS: A COMPARISON OF 3 HTLV 1 ANTIBODY ASSAYS

Vercauteren, Gaby*, Colebunders, R.*, Ryder, R.**, Laga, M.*, Piot, P.*, van der Groen, G.*
* Institute of Tropical Medicine, Antwerp, Belgium; ** Projet SIDA, Kinshasa, Zaire.

Objectives: Determination of the prevalence of antibodies against HIV-1 and HTLV-1 in sera collected in urban and rural areas of Zaire, Kenya and Belgium. Comparison of 3 assays for the detection of HTLV-1 antibody.

Methods: 2029 sera of African (Zaire, Kenya) or European (Belgium) origin were screened for HIV-1 and HTLV-1. Three screening assays for detection of HTLV-1 antibodies were used as HTLV-1 EIA (Dupont) HTLV-I Vironostika EIA (Organon) and the Serodia ATLA (Fujirebio). Sera were tested for anti-HIV antibodies with the HIV Vironostika (Organon). Repeatedly reactive samples were confirmed with WB (HTLV-1 or HIV). The WB was interpreted positive if both gag and envelope antibodies were present.

Results: Populations at different risk: (A: prostitutes, B: non-prostitutes; C: AIDS suspects; D: TB patients and E: gay men) were included in this study. HTLV-1 and HIV prevalences in the different groups were respectively: Kinshasa: A: 6.4 % - 37.8 %; C: 4.2 % - 79.8 %; D: 0.5 % - 39.6 %; Equateur: A: 8.1 % - 17.7 %; B: 1.3 % - 5.9 %; Nairobi: A: 0.8 % - 59.2 %; B: 1.7 % - 1.7 %; Antwerp: E: 0.3 % - 3.7 %. After comparing the HTLV-1 assays, we found 1715 sera negative in all three assays. On 355 sera, which were reactive in at least one kit, WB was performed. 36 % of these sera showed an indeterminate (IND) WB result. Sensitivity and specificity of the different brands were respectively: 79.4 % - 98.4 % (Dupont), 77.8 % - 96.4 % (Organon) and 86.1 % - 94.6 % (Fujirebio) (IND WB results was not included).

Conclusions: The HTLV-1 prevalence depended mainly on the geographical region and less on the population tested. There was no significant correlation between HIV-1 and HTLV-1 infection. The 3 HTLV-1 assays had comparable performances. However, in a substantial number of cases the WB result was not interpretable.

T.B.P.109

HIV2 infection in 2 european haemophiliac patients.

Simon,François*; PUEL,J**; HAMMER,F***; COURGNAUD,V****, KIRPACH,P***; BRUN-VEZINET,F* et al.
*Laboratoire de virologie, Hopital Claude Bernard, Paris, France. **Laboratoire de virologie, Hopital Purpan, Toulouse, France. ***Centre hospitalier du Luxembourg, Luxembourg. ****Laboratoire de biologie moléculaire, Faculté Necker, Paris, France.

We reported HIV2 infection, recently diagnosed, in 2 european patients with haemophilia A.
The first patient is a 16 year old french boy, with moderate (2%) factor VIII deficiency. He received cryoprecipitates since 1978. In 1980 he developed a persistent generalized lymphadenopathy. The second patient is a 12 year old portuguese boy. Before 1982 he was treated in Portugal with cryoprecipitates and total blood transfusions. He has been living in Luxembourg for 6 years. He was asymptomatic until 1988 when he presented with a zoster infection.
In the both patients, HIV1 Elisas, (Elavia 1, Diagnostics Pasteur, DP and Abbott EIA) were positive. HIV1 WB (New LAV Blot 1, DP) was unconclusive with only reactivities on the gag-pol antigens. Diagnosis of HIV2 infection was assessed by Elavia (Elavia II, DP) and by WB showing strong reactivities on the glycoproteins of HIV2: gp140, gp105, gp36. Sera were also tested by a dot assay using HIV2 transmembrane synthetic peptide and by RIPA (CEM-HIV2$_{ROD}$). From the peripheral blood lymphocytes (PBL) of the second patient a cytopathic HIV2 strain was isolated. PCR using HIV2 LTR env and pol primers detected HIV2 DNA in the fresh mononuclear cells from the PBL.
In these 2 patients, without any other risk factor except haemophilia, we diagnosed HIV2 infection. Studies of the blood donors are under investigation. This observation demonstrates the need of screening all the european haemophiliac patients for the detection of HIV2 antibodies.

T.B.P.110

DETECTION OF HIV-1 IN CULTURED PERIPHERAL BLOOD LYMPHOCYTES FROM HIV-SEROPOSITIVE HEMOPHILIACS.

Knight, Susan; Scheid, E.E.; Laurie, K.E.; Rosenthal, K.L. and Harnish, D.G.
McMaster University, Hamilton, Ontario.

Objective. To assess HIV-1 replication in cultured peripheral blood lymphocytes (PBLs) of HIV-seropositive hemophiliacs.
Methods. PBLs isolated from 48 HIV-seropositive hemophiliacs were cultured for two weeks *in vitro* following stimulation with PHA and IL-2. Cultured PBLs were assessed for HIV by reverse transcriptase (RTase) assays, *in situ* hybridization (ISH), indirect immunofluorescence (IIF), and gene amplification by the polymerase chain reaction (PCR).
Results. Cultures which were positive by IIF were also ISH positive. A subset of cultures (N=11) was positive for RTase and negative by IIF and ISH. Three patterns of RTase activity were observed; maximums at day 2 (n=4), day 7-10 (n=4), and day 13-15 (n=3). A subset (N=8) of seropositive hemophiliac cultures were PCR positive for HIV proviral gag-region sequences in the absence of evidence for HIV replication in cultured PBLs by other techniques. We are currently assessing RTase-, IIF-, ISH-negative cultures by PCR utilizing LTR- gag-, pol-, and env-region oligonucleotide primers.
Conclusion. PCR gene amplification detects HIV infection in cultured PBLs which are negative by other techniques. RTase is more sensitive than ISH on cultured PBLs and RTase patterns may correlate with numbers of circulating infected PBLs. Supported by National Health and Welfare (Canada).

T.B.P.111

THE EFFECTS OF PHORBOL ESTER(TPA) AND IODO-DEOXYURIDINE(IUDR) ON THE ISOLATION AND DETECTION OF HIV FROM SEROPOSITIVE INDIVIDUALS

Qualtiere, L.F.*; Zbitnew, A. and Conly, J., Dept. of Microbiology, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

OBJECTIVE: To determine if treatment of lymphocytes from HIV seropositive individuals with TPA or IUDR, prior to in vitro culturing would enhance virus recovery and/or increase the rate of isolation of HIV.
METHODS: Peripheral blood lymphocytes (PBL's) from HIV seropositive individuals at different stages of infection (4 ARC and 3 AIDS) were isolated on Ficoll-Hypaque gradients, treated for 24 hours with TPA (40 ng/ml) or IUDA (100 ug/ml) and then placed in culture with donor lymphocytes. At 7, 14 and 21 days the cultures were assayed by the Reverse Transcriptase assay for the presence of HIV.
RESULTS: In the five cases that were successful in virus isolation, the prior incubation of PBL's with TPA from HIV seropositive individuals augmented virus isolation in one case. IUDR enhanced isolation attempts in three, while in one patient both TPA and IUDR inhibited virus isolation, while in another neither augmented or inhibited virus isolation.
CONCLUSIONS: Prior treatment of PBL's with either TPA or IUDR can lead in some cases to dramatic increases (6-10 fold) in viral replication during standard isolation protocols. However, this augmentation is not universal suggesting in fact that the patient's own lymphocytes may be able to control viral replication in vitro or the ability to activate latent virus with these compounds varies dramatically from patient to patient.

T.B.P.112

T-CELLS VERSUS MACROPHAGE FOR ISOLATION OF HIV FROM BLOOD.

Fowler, Arnold*; Redfield, R.R.**; Gendelman, H.**; Kriebel, P.*; Meltzer, M.**; Oster, C.**; Burke, D.S.** *GRA Technologies, Inc., **Walter Reed Retrovirus Research Group, Walter Reed Army Inst. Res. Washington, D.C, U.S.A.

Objective: To compare T-cell cultures versus macrophage cultures for isolation of HIV from patient peripheral blood mononuclear cell (PBMC's).
Method: PBMC's were obtained by density gradient fractionation of heparinized blood from 48 staged HIV seropositive and from 13 seronegative but HIV-exposed persons. Approximately 10^6 cells were cocultured with: (A) PHA and IL-2 stimulated unfractionated target normal donor PBMC's, and either (B) CSF-1 stimulated target adherent normal donor PBMC's, or (C) purified elutriated monocytes.
Results: Isolation frequencies from seropositive patients (T-cell vs adherent and elutriated monocytes) were: Stg 1 patients, 3/5 vs 1/2 and 1/3; Stg 2 patients, 18/25 vs 3/6 and 12/19; Stg 3 patients, 11/14 vs 5/10 and 2/4; Stg's 4-6, 4/4 vs 3/4 (not performed using elutriated monocytes). The overall isolation rate for seropositive patients was 75% on T-cells and 56% on macrophages. When both culture systems were used concurrently, at least one culture was positive in 83% of the specimens. T-cell cultures became positive earlier (mean = 11 days) than did macrophage cultures (mean = 21 days). None of the cultures from 13 seronegatives were positive.
Conclusion: HIV is readily rescued from PBMC's of seropositive persons in cultures of either T-cells or macrophages, irrespective of the stage of illness.

T.B.P.113

FREQUENCE D'ISOLEMENT DU VIRUS HIV DANS LE SANG ET LES SECRETIONS VAGINALES DE FEMMES SEROPOSITIVES.

(T.D. LY*, S. HOFFMEISTER-BARCELLOS**, G. HENRION,*** J.P. COULAUD****, F. CATALAN*)
* Institut Alfred Fournier - Paris
** Service de bactériologie, hospital das clinicas, Porto Alegre (Brésil)
*** Chef du service de gynécologie obstétrique de la maternité Port-Royal (Paris)
****Chef des services cliniques, Institut Alfred Fournier, Paris

Objectifs : 1- Confirmer les chiffres à propos des pourcentages d'isolement du virus dans les sécrétions génitales, vérifier l'efficacité du Chlorure de Benzalkonium in vivo, comparer le taux de virus circulant chez les femmes séropositives asymptomatiques et symptomatiques.
Matériel et méthodes : deux groupes de femmes ont été constitués :
- groupe 1 : 24 femmes séropositives asymptomatiques, enceintes, qui viennent pour une IVG. 15 ont seulement été retenues.
- groupe 2 : 10 femmes séropositives symptomatiques (6 ARC, 4 SIDA). Le virus est isolé à partir de lavages vaginaux effectués avec 5 ml de milieu de culture, entre le 7e et le 20e jour après les règles pour les femmes du groupe 2, avant et après application d'un gel dosé à 0,1 % de Chlorure de Benzalkonium. Les liquides de lavage et le sang de la patiente sont mis en co-culture avec 10^6/ml lymphocytes humains normaux, stimulés depuis 3 jours par la PHA. Le liquide de lavage, après application du produit, est dilué à 10^{-1}, 10^{-2}, 10^{-3} et 10^{-4}. La positivité est établie par l'observation de l'effet cytopathique et le dosage de P24.
Résultats : Dans le groupe 1, le taux d'isolement est de 26,7 % dans le sang et 13,3 % dans les liquides de lavage des mêmes. Dans le groupe 2, le taux d'isolement dans le liquide de lavage a été de 37,5 % donc significativement plus élevé que dans le groupe 1. Les liquides dilués entre 2 $x10^{-1}$ et 2 x 10^{-2} conservent un pouvoir inhibiteur sur une culture de HIV 1 entretenue en CEM, contenant 22 ng/ml de P24.
Conclusions : Le taux d'isolement du virus HIV a été bien inférieur chez les femmes asymptomatiques, et est deux fois moins fréquent dans les sécrétions que dans le sang, ce qui est en accord avec la littérature. Le Chlorure de Benzalkonium garde, au bout de 4 heures, une activité anti virale importante (20 à 200 fois) ce qui est en faveur d'un pouvoir protecteur.

T.B.P.114

DEVELOPMENT OF A SENSITIVE MICROASSAY FOR THE MEASUREMENT OF RELATIVE NUMBER OF LYMPHOCYTES INFECTED WITH HIV.

Gupta, Phalguni; Ho, M.; Enrico, A.; Doerr, M. and Rinaldo, C.
University of Pittsburgh, Pittsburgh, PA 15261, U.S.A.

Objective. To determine the relative number of HIV-infected lymphocytes by a sensitive micro-cell dilution procedure.
Methods. Serial dilutions of patients' lymphocytes (10^2-10^5) were cocultivated with $1x10^6$ PHA-stimulated normal cells in 24-well microtiter plates in the presence of 20% FCS and 5% IL-2. Production of HIV was measured by the antigen capture test after two weeks of cocultivation.
Results. HIV was isolated from patients' lymphocytes in a concentration dependent manner. HIV was isolated from as few as 1000 cells from an AIDS patient and from 10,000 lymphocytes from an asymptomatic man. The microassay was compared with a standard HIV culture method for the isolation of HIV from 10 AIDS patients and 22 asymptomatic men. Results indicate that both of these procedures have comparable sensitivity for the isolation of HIV. Frozen patients' lymphocytes also showed positive virus culture in microassay. However, the sensitivity of HIV isolation was somewhat lower when frozen cells were used.
Conclusion: The micro-cell dilution assay provides a simple, inexpensive, sensitive and quantitative measurement for the number of HIV-infected lymphocytes. Since the microassay uses only $2\text{-}3x10^5$ patients' lymphocytes, the assay is also most suitable for HIV isolation from HIV-infected infants or from AIDS patients with extremely low T cell counts. Micro-cell dilution assay can be applied to measure the efficacy of an antiviral drug on the relative number of HIV-infected lymphocytes in a clinical trial. This microassay is a candidate measure for following the quantitative antiviral effect of a drug.

T.B.P.115 REFLEXIONS SUR L'ISOLEMENT DU VIH DANS UNE UNITE DE VIROLOGIE HOSPITALIERE

Fleury, Hervé J.A.*; Delord, B.* et Masquelier, B.*.
* Laboratoire de Virologie, CHR de Bordeaux et Université de Bordeaux II, Bordeaux, France.

Objectif. Dégager les enseignements (comparaison avec d'autres paramètres, intérêt) de plus de 400 mises en culture du VIH.

Méthodes. Plus de 400 mises en culture de cellules mononucléées du sang circulant ont été effectuées chez plus de 200 sujets (patients suivis dans le cadre d'un protocole thérapeutique, enfants nés de mères infectées, cas de contamination douteux avec autres paramètres négatifs .../...). Le virus a été détecté dans le surnageant des cultures cellulaires par mise en évidence de la protéine p24 du VIH 1 et d'une activité RT. D'autres paramètres biologiques ont été appréciés (antigénémie VIH 1, nombre de lymphocytes TCD_4 .../...) au moment de la mise en culture.

Résultats. Plus de 200 souches de VIH 1 ont été isolées (efficience = 50 %) ; on peut tirer les enseignements suivants :

- Une antigénémie VIH 1 positive est pratiquement toujours associée à un isolement viral.
- On peut isoler le virus chez des sujets dont le nombre de lymphocytes TCD_4 est effondré au moment de la mise en culture.
- Le virus peut être réisolé chez des patients recevant de l'AZT depuis plusieurs mois.
- L'isolement viral demeure une technique de choix pour l'établissement d'un pronostic chez les enfants nés de mères infectées.
- Dans un cas, nous avons isolé le VIH 1 chez un sujet dont les autres paramètres sont demeurés négatifs.

T.B.P.116 DUAL SEROLOGIC REACTIVITY FOR HIV-1 AND HIV-2 IN ABIDJAN

Porter, A.*; Lee, S.**; De Cock, K.**; Colebunders, R.**; Demet, G.***; Rayfield, M.** et al.
*Projet RETRO-CI; **AIDS Program, Centers for Disease Control, Atlanta, GA, USA. ***Institut Pasteur, Abidjan, Cote d'Ivoire.

Objective. To assess the spectrum of serologic reactivity of HIV infected patients in Abidjan; assess the predictive value of ELISA for HIV-1 and HIV-2 infection; and examine dual serologic reactivity by peptide ELISA and polymerase chain reaction (PCR).

Methods. 927 hospitalized patients repeatedly reactive by ELISA for HIV-1 and HIV-2 will be confirmed by virus-specific Western blot (WB). A subset of these were tested by type-specific synthetic peptide ELISA (Pepti-LAV 1-2) and had lymphocytes collected for PCR and virus culture.

Results. Of 927 patients repeatedly reactive by ELISA (543 thus far tested by WB), 19% are HIV-1 only; 8% HIV-2 only; and 74% both HIV-1 and HIV-2. Of specimens dually reactive on ELISA, 81% were dually reactive on WB, 16% HIV-1 only, and 0.25% HIV-2 only. While 46% HIV-1 only and 57% HIV-2 only reactive specimens were confirmed by the appropriate WB, 97% of dually reactive specimens were reactive on HIV-1 and/or HIV-2 WB. Thirty-four specimens dually reactive on ELISA will be tested by PCR. On peptide ELISA, 19/34 (56%) were reactive only to HIV-1; 6/34 (18%) HIV-2 only; and 6/34 (18%) remained dually reactive. On WB alone, 28/34 (82%) of these specimens were considered dually reactive. Serologic results will be compared with those of PCR and virus culture.

Conclusion. In hospitalized patients in Abidjan, dual reactivity on whole virus ELISA is 97% predictive of WB confirmed HIV infection.

T.B.P.117 STANDARDIZATION OF HIV COCULTURE ISOLATION TECHNIQUES IN MULTICENTER CLINICAL TRIALS.

Hollinger, F. Blaine; Bremer, J.W.; and Rao, S.M.
Virology Reference Laboratory (VRL)/NIAID/AIDS Program, Baylor College of Medicine, Houston, Texas, USA.

Objectives. To evaluate and effect improvements in the isolation of HIV from PBMCs by laboratories participating in multicenter clinical trials as part of the AIDS Clinical Trials Group (ACTG)/NIAID/AIDS program.

Methods. Monthly coded whole blood samples are sent by the VRL to ACTG labs for culturing. After an initial evaluation period (7 months), the labs were ranked by their ability to isolate virus. A consensus HIV isolation protocol was developed after comparing the methods and materials used by labs that consistently isolated HIV to the methods employed by labs having difficulty isolating the virus.

Results. Critical factors in the isolation procedure include volume of patient blood processed, centrifugation parameters used to recover PBMC, use of fresh (vs frozen) normal donor PBMC, concentration of PHA-P in donor stimulation medium, use of natural (vs recombinant) IL-2, time interval before addition of PHA-stimulated donor cells to patient PBMC, ratio of donor to patient PBMCs, concentration of cells in coculture, and weekly addition of fresh PHA-stimulated donor cells to coculture. The inclusion of polybrene and anti-alpha interferon in the stimulation or coculture medium did not improve isolation efficiency. Since the introduction of the consensus protocol, labs with poor performance status have shown a significant improvement in their ability to isolate HIV.

Conclusion. Achieving equivalent efficacy in isolating HIV from PBMC by the ACTG labs will permit the introduction of more sophisticated virologic end point cell culturing techniques for evaluating various antiviral treatment protocols.

T.B.P.118 TISSUE CULTURE AND P24 METHODS OF HIV DETECTION COMPARED AND CORRELATED WITH DEMOGRAPHIC DATA IN SYMPTOMATIC ARC PATIENTS

Hamilton, John; Compton, C.; Weinhold, K.; Simberkoff, M.; Hartigan, P.; and the VA Cooperative Study Group on The Treatment of ARC. Veterans Administration Medical Center, Durham, NC, USA.

Objective. To compare two methods of HIV detection in symptomatic ARC patients and to correlate the results with demographic data.

Method. A baseline blood sample was collected from each of 152 symptomatic ARC patients entering a multicenter, phase III trial of AZT. It was transported overnight and processed by two methods: (A) by standard cocultivation techniques and sampling the culture weekly for 4 weeks by antigen capture; (B) by directly measuring p24 levels in the plasma by standard antigen capture. Results were compared with demographic data.

Results. Method A detected HIV in significantly more patients than Method B did (41 vs. 7%). Method A was positive more often for (a) patients younger than 35 vs. those older (53 vs. 40%), (b) patients with T4 counts between 200-299 vs. 300-500 (53 vs. 37%), (c) patients who were anergic vs. those responsive to skin tests (50 vs. 37%). There were no significant differences for sex, race, risk group, or hospital. For the comparisons done, there were also no significant differences for culture time to positive or for absolute p24 levels. Methods A and B correlated in 62% of the patients but not in 38%; statistically, this is no better than could be achieved by chance.

Conclusion. Tissue culture is a more sensitive measure of HIV than is plasma p24 in this patient group, especially in those who are younger, anergic, and have the lower T4 counts. The tests may be measuring different stages of viral replication.

T.B.P.119 SENSITIVITY OF U.S. FDA LICENSED HIV-1 ENZYME IMMUNOASSAYS FOR DETECTION OF HIV-2 ANTIBODIES

George, J. Richard*; Rayfield, M.*; Schochetman, G.*; Heyward, W.*; Odehouri, K.**; Soudrey, R.,*** et al. *Centers for Disease Control, Atlanta, GA, USA; **Projet Retro C.I., Abidjan, Cote d'Ivoire; ***National Laboratories, Ouagadougou, Burkina Faso.

Objective. To determine the efficacy of testing for antibodies to human immunodeficiency virus (HIV) type 2 by screening with FDA licensed HIV-1 enzyme immunoassays (EIAs).

Methods. West African sera were tested for antibodies to HIV-1 and HIV-2 with EIAs employing both viral lysate and synthetic peptide antigens and with HIV-1 and HIV-2 Western blots. Based on these results, 55 HIV-2 sera, 39 HIV-1 sera, and 48 sera equally reactive with HIV-1 and HIV-2 immunoassays were selected for testing with U.S. FDA licensed HIV-1 antibody EIAs (see table).

Results. The percentages of sera that were positive by each EIA test are presented in the following table:

SERA	Ortho	ENI	Organon Teknika	Abbott Lab.	DuPont	Gen. Sys.	Cell. Prod.
HIV-2	60.0%	67.3%	70.9%	81.8%	87.2%	90.9%	90.9%
HIV-1	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%
HIV-1/2	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%

Conclusions. Sera from HIV-2 infected individuals will be detected by HIV-1 EIAs at a rate ranging from 60.0% to 90.9%, depending on the test used. Screening the blood supply with HIV-1 EIAs will not detect all HIV-2 infected units.

Diagnostic : contrôle de la qualité et techniques rapides
Diagnosis: Quality Control and Rapid Techniques

T.B.P.120

EVALUATION D'UN TEST DE DETECTION RAPIDE DES SUJETS SEROPOSITIFS POUR HIV 1 ET HIV 2.

(F. CATALAN, A. MILOVANOVIC, T.D. LY) - Institut Alfred Fournier - Paris

Objectif : Evaluer la sensibilité et la spécificité d'une technique ELISA rapide sur membrane de nitrocellulose, contenant deux spots de peptides recombinants, l'un correspondant à un épitope de la Gp 41 pour HIV 1, l'autre à un épitope de la Gp 105 pour HIV 2.

Méthodes : un groupe de patients séropositifs (technique ELISA Organon et Dupont de Nemours), confirmés par Western blot (New blot Pasteur et/ou Dupont de Nemours) a été sélectionné parmi les patients suivis pour leur séropositivité (TCD4, TCD8, Beta-2-glycoprotéine, dosage des immunoglobulines, etc...) (163 patients) a permis d'étudier la sensibilité.
L'autre groupe (110 patients) a été constitué de patients séronégatifs par les techniques précédentes et aucun ne contenait d'antigène. Dix sérums de patients africains ayant une infection à HIV 2 , isolé, ont été inclus. Le test a été effectué à partir de sang total recueilli sur EDTA.

Résultats : 7 sérums, adressés pour suivi de séropositivité, ont été trouvés négatifs dans toutes les techniques, infirmant donc cette séropositivité.
Aucun résultat discordant n'a été relevé. Les 10 sérums HIV 2 n'ont répondu qu'au spot HIV 2. La sensibilité et spécificité ont été de 100 % dans ce cas.

Conclusion : Ce test rapide (cinq minutes), pouvant s'adapter à toutes les situations expérimentales, permet avec une sensibilité et spécificité excellentes, de préciser l'infection HIV1 et/ou HIV2, alors que les deux virus montrent une grande homologie, tout au moins dans les protéines du core.

T.B.P.121 PROFICIENCY IN PERFORMING HIV P24 ANTIGEN EIAS AND COMPARABILITY OF RESULTS IN A MULTICENTER QUALITY ASSURANCE PROGRAM

Bremer, James W.*; Hollinger, F.B.*; Haywood, M.D.*; and Myers, L.E.**
*Virology Reference Laboratory/NIAID/AIDS Program, Baylor College of Medicine, Houston, TX, USA; **Research Triangle Institute, Research Triangle Park, NC, USA.

Objectives. To reduce the variance for within laboratory performance of HIV p24 antigen EIAs and to achieve comparability of data between laboratories when different commercial assays are used.
Methods. AIDS Clinical Trials Group (ACTG) labs participating in multicenter clinical trials for the NIAID/AIDS Program use commercial HIV p24 antigen EIA kits with standardized reference material and QC samples supplied by the Virology Reference Laboratory (VRL). Proficiency is examined with coded panels consisting of various concentrations of p24 antigen in either serum or medium.
Results. Prior to the introduction of uniform reference samples, median within laboratory variance was 21% on coded panel serum samples and 30% for medium samples. HIV p24 antigen recovery for EIA kits from different manufacturers ranged over more than an order of magnitude. To lessen the effect of kit variations and to increase the comparability of data between laboratories, a centrally supplied reference standard for preparing a standard curve and QC check samples (0 and 100 pg/mL in serum or medium) are used in each assay. After the introduction of a uniform standard, 30 of 38 participating ACTG facilities exhibited within laboratory variance of less than 15% for results on proficiency panel samples.
Conclusion. The use of centrally supplied uniform reference materials and continual proficiency testing is essential for obtaining comparable and reliable data from laboratories in multicenter clinical trials.

T.B.P.122 IS A VIROLOGY QUALITY ASSURANCE (QA) PROGRAM ESSENTIAL FOR MULTICENTER CLINICAL TRIALS?

Hollinger, F. Blaine, and Bremer, J.W., Virology Reference Laboratory/NIAID/AIDS Program, Baylor College of Medicine, Houston, TX, USA.

Objective. To establish a strong QA program which will monitor virology labs participating in multicenter AIDS clinical trials sponsored by the NIH.
Methods. HIV isolation from PBMC using cocultivation techniques and HIV p24 antigen quantitation by EIA.
Results. In 1988, monthly evaluation of 30 labs revealed that only 13 (43%) were consistently able to isolate HIV from PBMC of coded blood samples at least 80% of the time. To remedy this, all centers were polled concerning their PBMC recovery and culture techniques. Data from fully certified labs were compared to data furnished by labs with poor performance credentials, and a consensus protocol for HIV isolation was formulated. Since this protocol was introduced, a significant improvement has occurred in those labs that did not meet minimum performance standards. During the same period, proficiency in performing HIV p24 antigen EIAs and comparability of different commercial assays were evaluated. Coded proficiency panels consisting of various concentrations of viral lysate in serum or medium were tested and the data analyzed. The results indicated, that to reduce the amount of in-house variance and to achieve comparability among labs using kits from different manufacturers, a QC correction factor and a centrally supplied reference standard to prepare standard curves were needed.
Conclusion. Validation of assay results is essential if comparability and uniformity of data is to be achieved in multicenter clinic trials. This can be accomplished through the use of an independent QA program that assesses all aspects of quality control. Such a program also can be used to identify and correct performance deficiencies in individual laboratories.

T.B.P.123 WESTERN BLOTS: INDETERMINATE RESULTS AND LOT-TO-LOT VARIABILITY IN ADULTS AT LOW RISK FOR HIV-1 INFECTION

*Garrison, Leslie; *Midthun, K.; **Fernie, B.; *Farzadegan, H.; *Clements, ML; and the NIAID AIDS Vaccine Evaluation Group. *Johns Hopkins University, Baltimore, Maryland, USA; **Georgetown University, Rockville, Maryland, USA.

Objectives. To examine the reproducibility of the Western blot (WB) and the prevalence of indeterminate WBs in individuals at low risk for HIV infection.
Methods. As part of a multicenter AIDS vaccine trial, 158 healthy adults at low-risk for HIV infection by questionnaire and with negative hepatitis B serology were tested by: Abbott HIV EIA, Abbott HIV EIA Antigen and Biotech/Dupont WB. Lymphocyte culture and polymerase chain reaction (PCR) for HIV were performed on cells from 114 and 78 volunteers, respectively. Follow-up serum specimens were collected after 4-12 months from 41 volunteers. The reproducibility of the WB was assessed by testing paired serum samples using kits of the same and different lots.
Results. Of 158 adults who were HIV-negative by all other assays, 68% had negative and 32% had indeterminate WBs. This indeterminate rate was higher than the 15% expected ($p<0.01$). Individuals with negative or indeterminate WBs were of similar race, sex, and age. The number of bands per individual ranged from 1 to 5 ($\bar{x}$ = 2.2 bands); 87% had an intensity less than the weak positive control and the rest were of equivalent intensity.

Lot-to-lot variability of WB results was noted. When 30 paired sera of individuals with indeterminate WBs were run in different lots, the reproducibility of a negative or indeterminate result was 60% and of identical band patterns was 40%. When these specimens were tested in the same lot, there was 97% concordance in interpretation and band patterns. When paired sera from 11 individuals with negative WBs were tested in different lots, there was 73% concordance in interpretation and band patterns. No positive WBs were identified. The most frequent bands corresponded to gag (p17, 24, 55) and pol (p51, 66) proteins. The most common band, p24, was present in 88% of indeterminate WBs. Its reproducibility was 74% using different lots and 92% using the same lot.
Conclusion. The prevalence of indeterminate WBs among HIV-negative individuals was 32%. This high rate and the lot-to-lot variability underscore the need for more specific tests to detect HIV infection. We caution against the use of the WB as an initial screening test.

T.B.P.124 DETECTION OF ANTIBODIES TO HIV-1 BY A RAPID, PEPTIDE-BASED IMMUNOASSAY

Montana, J.P.; Monji, N.; Cole, C.A.; Gosting, Larry; and Coleman, P.
Genetic Systems Corporation, Seattle, Washington, U.S.A.

Objective. To develop a rapid (10 min) synthetic peptide-based immunoassay for the accurate detection of antibodies to HIV-1 for diagnostic purposes.
Methods. A synthetic peptide representing a highly conserved immunodominant region of gp 41 was adsorbed to latex beads which were subsequently spotted onto a nylon membrane. The membrane was incorporated into a plastic molded device containing an absorbent pad. Serum or plasma diluted 1:10 was filtered and applied to the membrane, washed with buffer, and the immunochemical reactions were visualized by the sequential dropwise addition of enzyme-anti-Ig conjugate and chromogenic substrate. The large antigen surface area and sample flow-through allow for extremely rapid immunochemical binding kinetics, which effects immunoconcentration of the anti-HIV-1 immunoglobulins.
Results. This assay detected anti-HIV-1 antibodies in:
1) 0/1187 normal blood donor sera
2) 0/123 patients' sera with potentially interfering substances
3) 0/79 immunoblot negative/whole virus EIA positive sera
4) 0/209 immunoblot atypical/whole virus EIA positive sera
5) 164/164 immunoblot positive/ whole virus EIA positive sera
Therefore, 100% sensitivity and 100% specificity were calculated using immunoblot as the reference method.
Conclusion. This peptide-based assay, which in this study is as sensitive and specific as immunoblot, represents a useful diagnostic test which is easily and rapidly performed.

T.B.P.125 A SIMPLIFIED 5 MINUTE STAINING PROCEDURE FOR HIV WESTERN BLOTS USING PROTEIN-A COLLOIDAL GOLD.

Chun, P. K. and A. K. Chu.
E-Y Laboratories, Inc., San Mateo, California 94401, U.S.A.

Objective: To develop a rapid and simple staining procedure for HIV Western Blots which requires no equipment.
Methods: Western Blot analysis has been used to confirm test results of ELISA based screening tests for HIV antibodies. The Western Blot strips are now commercially available, but the staining procedures available are still lengthly (several hours to overnight incubations) and complex, requiring extensive hands-on time. Frequently equipment and staff to run this sophisticated procedure are not available, especially in third world countries. Furthermore, thre are situations in which a more rapid confirmation is desired. In the last meeting, we described a 5 minute membrane based screening test (HIVCHEK™) which used Protein-A colloidal gold to visualize the captured HIV antibodies. The test had been extensively evaluated by several centers and has been shown to perform well. We have further developed the chemistry and a method which can accomodate commercially available Western Blot strips into a convenient confirmatory test. The entire procedure can be completed in 5 minutes without the need for accurate volumetric pipetting or the need for equipment such as shakers or incubators.
Results: The procedure is being evaluated using Western Blot strips from several different manufacturers. Initial results indicate that it is suitable for most strips. Full details of the technique and protocol will be presented at the conference.

T.B.P.126 UTILITY OF A RAPID ANTIBODY ASSAY FOR DETECTION OF HIV-1 INFECTION IN PATIENTS ATTENDING AN EMERGENCY DEPARTMENT

Kline, Richard*; Kelen, G.D.**; Brothers, T.A.**; Quinn, T.C.*.
*NIAID, NIH, Bethesda, Maryland; **Johns Hopkins University, Baltimore, Maryland, U.S.A.

Objective. To evaluate the reliability, sensitivity and specificity of the Genetic System HIV-1 rapid antibody detection immunodiagnostic assay (RADIA) compared to ELISA and Western blot among patients in an emergency medical care setting.
Methods. Sera from 500 patients attending an inner-city emergency room (ER) were evaluated for HIV-1 seropositivity by a synthetic peptide based assay called RADIA (Genetic Systems). This assay uses microparticles coated with a synthetic peptide representing an immunodominant region of gp41. Sera that tested positive were scored according to color intensity and repeated duplicate. All sera were analyzed by ELISA (Organon) and any sera reactive by either ELISA or RADIA were confirmed by Western blot (WB).
Results. The RADIA test system required no special skills or equipment. Results for 10 specimens could be determined in approximately 10 minutes. Of 500 ER patients, ELISA and WB analysis detected 25 (5.0%) antibody positive patients and 3 patients with indeterminate WB. RADIA detected all 25 patients positive sera and one specimen that was WB negative, for a sensitivity of 100% and specificity of 99.79%. RADIA did not detect 2 samples that were indeterminate by WB (p31, gp160; gp160), but did detect one sample that ELISA negative and WB indeterminate (p24).
Conclusion. In this population, RADIA demonstrated a high sensitivity and specificity for detection of HIV-1 infection comparable to ELISA and WB testing. The assay was extremely rapid and versatile providing initial HIV-1 serologic results within 10 minutes.

T.B.P.127 EVALUATION OF A RECOMBINANT HIV-1 ENZYME IMMUNOASSAY (EIA) IN PATIENTS ATTENDING AN EMERGENCY ROOM AND A SEXUALLY TRANSMITTED DISEASE CLINIC

Kline, Richard L.*; Kelen, G.D.**; Hook, E.W.**; Brothers, T.A.**; O'Sullivan, S.M.**; Quinn, T.C.*.
*NIAID, NIH, Bethesda, Maryland; **Johns Hopkins Medical Institutions, Baltimore, Maryland.

Objective. To evaluate the reliability, sensitivity and specificity of the Syva Microtrak Recombinant HIV-1 EIA compared to a commercially licensed EIA and Western blot.
Methods. 2000 patients attending an emergency room and sexually transmitted disease clinic were tested for HIV-1 seropositivity using a recombinant HIV-1 EIA (Syva). This EIA uses genetically engineered gp41 and gp120 and p24 gene products of HIV-1 expressed in E. coli. After purification, all immunologically detectable bacterial proteins were removed. All sera were also analyzed by EIA (Organon) and sera which were repeatedly reactive by either assay were confirmed by Western blot (Dupont).
Results. The Syva Microtrak HIV-1 EIA procedure was easy to perform with short in-cubation times and color-coding of reagents to lessen the chances of error. In assessing HIV-1 seropositivity in the two populations, the Organon EIA and Western blot detected 119 positive and 5 indeterminate samples. The Syva EIA detected all 119 positive samples with no false positive samples. Compared to Western blot, the assay had a sensitivity of 100% and a specificity of 100%.
Conclusion. Use of the Syva Microtrak Recombinant HIV-1 EIA for detection of HIV-1 infection in these populations proved to be highly reliable with excellent sensitivity and specificity compared to a licensed EIA and Western blot.

T.B.P.128 DETECTION OF ANTI-HIV ANTIBODIES WITH SYNTHETIC PEPTIDES USING A 3 MINUTES RAPID TEST

Stéphane Bettinger*, J. Martin*, A. Hervanez**,
PK Tani**, C.Richardson***, A. Fraser** G. Sommé*
* Clonatec : 60 rue de Wattignies - 75012 PARIS - FRANCE
** V-Tech : POMONA, CA - USA - *** Syntro : SAN DIEGO, CA - USA

Objective : A 3 minutes immunofiltration ELISA device using synthetic peptides derived from the transmembrane glycoprotein of HIV1 and HIV2, was optimized for the detection and the distinction of anti-HIV antibodies in serum or whole blood samples.
Methods : The assay involved synthetic peptides coated on a membrane with one spot of HIV1 peptide, one spot of HIV2 peptide and one internal control ring. A diluted specimen is filtered through the reactive membrane. Anti-human Ig peroxidase conjugate substrate is added. The result is read visually. Results are recorded as positive if one or two blue dots and the peripheral blue ring appear on the membrane. Results are recorded as negative if the blue ring appear only.
Results : To evaluate HIV1 peptide, 280 sera positive for anti-HIV1 antibodies were tested. 276 were reactive with the HIV1 peptide (sensitivity = 98,9 %). 441 negative sera and 18 false positive sera in ELISA (with core reactivity) were negative (specificity = 100 %).
To evaluate HIV2 peptide, 46 anti-HIV2 sera were tested. All were reactive with this peptide (sensitivity = 100 %). Of 647 negative and 18 false positive sera, no reaction was observed (specificity = 100 %).
Conclusion : Target HIV is a sensitive and specific rapid test which can be performed handly for the screening and the typing of anti-HIV antibodies. After the evaluation of 991 sera, the sensitivity of the test is 99,45 % and the specificity is 100 %. We thank Dr. Ph. Poulesty.

T.B.P.129 USE OF A PEPTIDE-BASED, RAPID IMMUNOASSAY FOR THE DETECTION OF ANTIBODY TO HIV-1

Stout, R.L.* Fotopoulos, S.S*., Kyle, B., Hosseini, M., Ferrera, C.,**
Krieger, Monica S.**
*Clinical Reference Laboratory, Lenexa , KA. and **Genetic Systems Corporation, Seattle, WA. U.S.A.

Objective: To investigate the utility of a peptide-based, rapid immunoassay for detecting anti-body to Human Immunodeficiency Virus Type 1 (HIV-1).
Methods: 1595 samples were tested by a rapid immunoassay based on a synthetic peptide found in the conserved region of the viral transmembrane glycoprotein, gp 41 and by a whole-virus immunoassay. Repeatably reactive samples were also tested by Western blot (DuPont).
Results: Results of the tests were interpreted according to the package insert of each test.

Rapid Immunoassay	Microtiter EIA	Western Blot	Number of Samples
Negative	Negative	Not Tested/Neg	1383
Positive	Positive	Positive	101
Negative	Positive	Indeterminate/Neg	86
Negative	Negative	Indeterminate	21
Positive	Negative	Indeterminate/Neg	3
Positive	Positive	Indeterminate	1

Conclusion: The sensitivity and specificity of enzyme immunoassays and blot kits marketed for detection of antibody to HIV are greater than 99%; however, when a low prevalence population is tested a high percentage of the reactive samples are false positives or blot indeterminate. Preliminary results indicate that a peptide-based test may be useful in distinguishing samples which are false positive by EIA or indeterminate by Western blot.

T.B.P.130 COMPARISON OF SERUM AND PAPER-ABSORBED FINGERSTICK BLOOD SAMPLES FOR DIAGNOSIS OF HIV INFECTION IN INTRAVENOUS DRUG USERS.

Hoff, Rodney*; Steger, K.**; Deutsch, G.*; Weiblen, B.*; Comella, B.** and Craven, D.**.
*Massachusetts Department of Public Health, Center for Disease Control;
**Boston City Hospital, Boston, Massachusetts, USA.

Objective. To determine whether the results of HIV ELISA and immunoblot (IB) assays on paper absorbed (PA) fingerstick blood are equivalent to that obtained with serum specimens.
Methods. Paired specimens of venous blood serum and fingerstick blood absorbed and dried onto S&S 903 collection paper were obtained with consent from 393 clients using a walk-in anonymous counseling and testing service for intravenous drug users. The paired serum and PA specimens were tested by ELISA (Genetic Systems) and the Miniblot® IB procedure.
Results. The same group of 66 IB-confirmed ELISA-positive clients was detected by examining the serum and the PA specimens. The IB band patterns in the 66 paired specimens were identical. By ELISA 18% of sera (72/393) and 19% of PA specimens (76/393) were repeatedly reactive, and the relative strength of ELISA reactivity in the paired specimens was virtually identical (r=0.94). A slightly higher ELISA mean background with PA specimens (45% of the cutoff vs 27% for serum) resulted in 10 non-IB confirmable ELISA positives in contrast to 6 for serum.
Conclusion. PA specimens, as compared to serum, provide for equivalent sensitivity and specificity in ELISA and IB assays for HIV antibodies. Moreover, the PA method is superior in convenience, safety, transport, and processing--all of which are advantages for serosurveys and screening programs, especially when venipunctures are problematic.

T.B.P.131 THE ANTI-HIV TESTING BY QUICK TESTS AND A COMPARISON WITH A STANDARD ENZYME METHOD

Das, P.C., de Vries, A.H.; McShine, R.L.; Smit Sibinga, C.Th; Red Cross Blood Bank Groningen-Drenthe, Groningen, Teh Netherlands.

To provide rapid but sensitive and anti-HIV specific testing we have compared HIV check (DuPont), gelatin particle agglutination (Fujirebio) tests with our routine enzyme immuno assay (EIA - Wellcome) used for routine testing of 60,000 donations per year.
Initial screening consists of: 3 Western blot positive donor sera, 5 'tricky' samples (P24 and/or P55 bands) and healthy donor sera (40). In the second phase 5 Western blot positive sera were diluted and run in parallel. All tests were carried out according to the manufacturers' instructions.
Results:

		TESTS		
Initial screening		HIV-check	Fujirebio	EIA
	HIV pos (n= 3)	All pos	All pos	All pos
	Tricky (n= 5)	All neg	All neg	All neg
	Normal (n=40)	1/40 pos	All neg	All neg

In the rapid HIV check test all the positive samples were clearly identified and tricky sera remained negative. Fujirebio is at least 3-fold sensitive in end point dilutions (16002 vs 2048 in EIA). HIV check is fairly quick (30') having a high sensitivity and specificity (1/40 initial non-specific reaction) Fujirebio showed very high specificity and sensitivity, and seems adapted to rapid testing.

T.B.P.132 A SIMULTANEOUS UNIDOT QUICK TEST FOR DETECTION OF HIV-ANTIBODY AND HBs ANTIGEN FOR BLOOD SCREENING.

Takeda, K. Augusta*; Hardy, J.**; Wilson, A.J.**; Schmal, M.R.***; Yamada, F.T.***; Provessana, M.M.***.
*Akita, São Paulo, Brasil;**Gull Foundation for Medical Research, Salt Lake City, Utah, USA;***Emilio Ribas Hospital, São Paulo, Brasil.

Objectives: The developing countries are in urgent need of an easy and economical screening test for HIV-Ab and HBsAg for use in parallel with other assays in order to eliminate false negatives/positives. This test detects, at the same time, HIV-Ab and HBs-Ag using whole blood, plasma or sera.

Methods: HIV-Ab and HBs-Ag was spotted in each well of a 96-well test card. The card is placed in a tray. Add 1 drop of undiluted specimen to the well. Incubate at room temperature for 10 minutes. Was the card with buffer shaking the tray for 10 seconds. Discharge the buffer and repeat operation for 3x. Add enough conjugate to the tray to completely immerse the card. Wait 10 minutes at room temperature. Pour off the conjugate and wash 3 x. Add color developer and incubate for 10 minutes. Pour off the solution and wash the card with water and read. The reaction is positive when the spot is colored.

Results: 480 clinical specimens of AIDS and hepatitis patients or suspected and normal donors were tested. Sensitivity was 99% and 100% of specificity when compared with other tests efficiency of the test = 99.5%.

Conclusion: This test is a very useful tool for screning, repetition or emergency situations.

T.B.P.133 FIELD EVALUATION OF IMMUNOBINDING AND AGGLUTINATION TESTS FOR HIV

Mitchell, Sheila*;Tukei, P.M.**;Mboup, S.***;Mingle, J.****; Lamptey, P.R.*
*AIDSTECH/Family Health International, North Carolina, USA, **Virus Research Center, Nairobi, Kenya, ***Universite Cheikh Anta Diop, Dakar, Senegal, ****Ghana Medical School, Accra, Ghana.

Objective. To evaluate one rapid test as a screening test for HIV and two agglutination tests as supplemental tests for HIV in field laboratories in 3 countries in Africa.
Methods. The HIVCHEK (Dupont, USA) was evaluated as a screening test with the SERODIA-HIV (Fujirebio, Japan) and RETROCELL (Abbott, USA) being evaluated as supplemental tests. A total of 6,000 specimens were tested in 24 laboratories in Kenya, Ghana and Senegal. Thorough, standardized training in these techniques was provided to all technicians.
Results. Sensitivity and specificity of the tests will be determined and compared with those of ELISA and Western Blot. Inter and intra country differences in test performance will be examined and reported.
Conclusion. With proper training the newly developed tests for HIV antibody can perform well in laboratories lacking specialized equipment. The use of these assays for screening and confirmation would facilitate blood donor screening in developing countries.

T.B.P.135 CONFIRMATION OF HIV INFECTION WITH A LINE IMMUNE ASSAY (INNO-LIA) USING WHOLE BLOOD IMPREGNATED FILTER PAPER DISCS

Kestens, Luc*; Pollet, D.E.**; Gigase, P.L.*; Vandenbruaene, M.*; Peeters, D.**, van der Groen, G.*
* Institute of Tropical Medicine, ** Innogenetics N.V., Antwerpen,Belgium.

Objectives. To evaluate the use of whole blood collected on filter paper in the INNO-LIA, a newly developed "second generation" HIV antibody confirmation test.
Methods. From each of 40 HIV+ subjects blood samples were collected in 4 different ways: anti-coagulant free capillary (1) and venous (2) whole blood as well as heparinized (3) whole blood were collected on Whatman 3MM Chr filter paper. In addition cell-free serum (4) was collected and kept frozen at -20°C until use. Blood impregnated filter papers were air dried, placed in a sealed plastic bag and stored at 4°C for at least 2 weeks prior to testing. Punched filter paper discs (6 mm) were eluted in 1 ml PBS supplied with 0.1% caseine, 0.2% Triton and 0.1% NaN_3. The same buffer was also used to dilute serum (1/100). The presence of antibodies against gag (p24 and p17), pol (endonuclease), env HIV-1 (gp41) and env HIV-2 (gp36) was assessed in the INNO-LIA according to the instructions of the manufacturer.
Results. The three different methods of sample collection on filter paper gave identical results which matched the results of a 1/100 dilution of serum. No selective loss of signals was observed with the paper discs as compared to the serum samples. Samples from patients with HIV-2 infection could easily be discriminated from subjects with HIV-1 infection and were in accordance with Western blot findings.
Conclusion. Whole blood impregnated filter paper can successfully be used to confirm infection with HIV when used in the INNO-LIA. This is of special interest in field studies where filter paper blood can easily be obtained and transported.

T.B.P.137 RAPID, MANUAL SCREENING TEST (HIVCHECK(TM) FOR ANTIBODIES AGAINST HIV-1 AND HIV-2

Pagels, William R.*; Galvin, J.P.*; Tirado, J.*; Reed, D.**; Chun, P.K.***; Chu, A.E.***.
*E. I. Du Pont de Nemours and Co., Inc., Wilmington, Delaware, USA.
**Du Pont de Nemours International S.A., Geneva, Switzerland.
***EY Laboratories, San Mateo, California, USA.

Objective. To develop an easy-to-use test that would simultaneously screen for antibodies against both viruses. Ultimately, to facilitate screening in developing nations and small labs in developed countries.
Methods. A number of peptides and recombinant proteins have been evaluated to sensitize the widely accepted HIVCHEK(TM) assay to HIV-2 only samples.
Results. The sensitivity of the original HIVCHEK(TM) assay to HIV-2 only samples has increased from approximately 30% to 100% in the populations tested. In these HIV-2 populations, samples can be diluted and still detected as positive on this modified HIVCHEK(TM) assay. In a preliminary study in France and Portugal, the modified HIVCHEK(TM) assay correctly identified all 15 samples from patients known to be infected with HIV-2. Detailed data from more extensive evaluations now in progress in Europe and Africa will be presented.
Conclusion. Antibodies to both viruses can be simultaneously screened for when a proper selection of antigens is made. Sensitivity and specificity remain excellent. Use of antigens from the envelope regions of the viruses' genomes as the antibody capture reagents have provided an excellent method of achieving this sensitization.

T.B.P.134 USE OF AGGLUTINATION ASSAYS AS SUPPLEMENTAL TESTS FOR ANTIBODY TO HIV

Tukei, Peter M.*; Mitchell, S.**; Nyamongo, J.***.
*Virus Research Center, Nairobi, Kenya, Africa, **Family Health International, Research Triangle Park, North Carolina, U.S.A., ***National Public Health Laboratory, Nairobi, KENYA .

Objective. To evaluate two agglutination assays for antibody to HIV as supplemental tests in field laboratories in Kenya.
Methods. A particle agglutination test SERODIA-HIV (Fujirebio, Japan) and a hemagglutination test RETROCELL (Abbott, USA) were evaluated for use as supplemental tests in comparison with the Western Blot. Seven laboratories in Kenya participated in the study. Serum from 2,000 blood donors, persons at high risk and suspected AIDS patients were initially screened by the HIVCHECK (Dupont, USA). All positive specimens and 10% of the negatives were then tested by SERODIA-HIV and RETROCELL. At the reference laboratory, duplicate samples were tested by ELISA. All samples positive by any test and 10% of the negatives were tested by Western Blot. Each test is being evaluated for sensitivity, specificity and usefulness in these field laboratories.
Results. With thorough training these tests can readily be performed in laboratories without sophisticated equipment. Data on sensitivity and specificity will be presented at the conference.
Conclusion. The agglutination tests do not require expensive equipment or highly trained staff and are more economical than the conventional supplemental tests used in HIV testing. These tests offer an alternative to the Western Blot technique as well as their intended use as screening tests.

T.B.P.136 A RAPID COLORIMETRIC EIA FOR DETECTION OF ANTIBODY TO HIV-1

R.K.Shockley*;T.Maitaki*;Mark White**;Brian Davis**; and Carlos Abel**
*Murex Corporation,Norcross,Georgia USA
**Institute for Cancer Research, San Francisco, CA,USA.

Objective. To develop a rapid, sensitive and specific colorimetric enzyme immunoassay for the qualitative detection of antibody to HIV-1 in specimens.
Methods. A simple, 10 minute colorimetric screening test was developed using Murex SUDS test cartridge and proprietary microfiltration EIA method.The test incorporates immunoaffinity purified HIV-1 antigen and synthetic peptide. A mixture of specimen and solid phase capture reagent is incubated 3 minutes at room temperature. Mixture is dispensed into a SUDS cartridge and unbound material is removed by addition of wash reagent to cartridge. Enzyme antibody conjugate is added to the cartridge and is allowed to incubate at room temperature for 3 minutes. Unbound conjugate is removed by addition of wash reagent to the cartridge. Following a 2 minute substrate development step, result is read from the bottom of cartridge. A distinct blue color indicates a positive test.
Results. Of 1316 specimens examined, 669 were negatives and 647 were positives. Observed sensitivity and specificity were 100% and 99.7%, respectively Positive predictive value was 99.7%. Negative predictive was 100%.
Conclusions. Murex SUDS HIV-1 antibody test provides an easy method for the detection of antibodies to HIV-1 and a total test time of approximately 10 minutes. Precision pipetting, specialised instrumentation and extensive training are not required.

T.B.P.138 MULTIPLE USE OF A SINGLE HIVCHEK(TM) DEVICE FOR SCREENING FOR HIV-1 ANTIBODIES.

Pagels, William R.*; Galvin, J.P.*; Mitten, C.M.*; Chun, P.K**; Chu, A.E.**; Tirado, J.*.
*E. I. Du Pont de Nemours and Co., Inc., Wilmington, Delaware;
**EY Laboratories, San Mateo, California, USA.

Objectives. To provide developing nations with the capability of using HIVCHEK(TM) to screen for HIV-1 antibodies by reducing the cost/sample tested. Maintain the simplicity and ease-of-use of the assay technique.
Method. Several techniques for regenerating the HIVCHEK(TM) device were evaluated so that a device may be reused with several samples. In the preferred protocol, only one more reagent addition step is required to regenerate the device.
Results. As reported earlier, HIVCHEK(TM) is a very accurate, (sensitivity =98.6, specificity=98.8) rapid test for the detection of antibodies to HIV. To make the assay even more useful in developing nations, a HIVCHEK(TM) device can be regenerated after a negative sample has been assayed on a device. This is best performed by washing the device with an acid solution prior to performing the assay another time on the same device. A single device can be used with a negative sample and still detect a weak positive sample on the subsequent test. The acid wash will not eliminate a visibly detectable positive spot on a device with the first sample. Further detailed results will be provided.
Conclusions. By reusing a device several times, the cost/sample analysed is significantly reduced thereby making the HIVCHEK(TM) assay significantly more affordable in developing nations. This regeneration of a device minimally impacts on the use of the HIVCHEK(TM) assay by clinicians.

T.B.P.139 A PARTICLE-AGGLUTINATION ASSAY FOR ANTI-HIV-1 IN DEVELOPING COUNTRIES

Rickard,Ema*;Muchinik,G*;Manca,M*;Pérez Bianco,R*;Pérez,H**;Cahn,P**
*IIHEMA,Academia Nacional de Medicina,**Hospital Juan A.Fernández,Buenos Aires,Argentina.

Objective. To evaluate the efficiency of a rapid and easy-to-use assay for HIV not requiring specialized equipment. There is an urgent need for this test in developing countries.
Methods. A particle-agglutination(PA) test (Serodia-HIV,Fujirebo,Inc.,Japan) was evaluated for screening of HIV antibodies in a panel of 504 frozen sera from high-risk individuals and in 250 blood donors. Results were compared with ELISA (Abbott) and confirmed by W.B.(Dupont) and/or IF.
Results. Out of the 205 HIV-1-positive-confirmed sera, the PA detected 198. In 7 sera the reaction was equivocal(±) but, as suggested by the manufacturer, it was scored positive. This gives a sensitivity of 100%. When we tested a panel of sera from blood donors, we observed a 95.1% specificity. The test had produced a considerable amount of false positive results.
Conclusion. In our hands, this assay showed to be very sensitive. Although specificity was not the one assumed by the manufacturer, it seems the test is suitable for use in blood banks in developing countries. Still, we have some doubts about its use with frozen sera from high-risk groups. Repeatedly frozen sera could give false positive reactions which should be avoided.

T.B.P.140 EVALUATION OF A NEW RAPID SCREENING ASSAY FOR HIV ANTIBODIES

Muchinik,Guillermo*;Rickard,E*;Picchio,G*;Manca,M*;Cahn,P**;Pérez Bianco,R*,et al.
*IIHEMA,Academia Nacional de Medicina,**Hospital Juan A.Fernández,Buenos Aires, Argentina.

Objective. To describe the efficiency of a very rapid test (less than 15 minutes), suitable for use in developing countries.
Methods. The "HIVCHECK" test(Dupont) was evaluated using 94 frozen sera from high-risk individuals and containing 56 sera HIV-1-positive by EIA(Abbott), confirmed by IF,ENVACORE(Abbott) or W.B.(Dupont), and 38 HIV-1-negative sera. Fresh serum from 50 blood donors was also evaluated.
Results. Out of 56 frozen sera repeatedly positive by EIA, the new test only detected 53, which gives a sensitivity of 93.3% and a specificity of 98.7%. When frozen and thawed samples were excluded and we considered only fresh-blood sera, the sensitivity of the test was 100% and the specificity, 98%. Although some frozen samples were processed as recommended by the manufacturer, they were not correctly absorbed to the paper and considered undeterminate. Some fresh sera were kept at 4°C for 1 week; we found 100% concordance of results between the first and the 1-week-later assays. There were no doubtful results and all the sera absorbed perfectly well to the filter.
Conclusion. The "HIVCHECK" is an excellent method to be used in developing countries, where there is a need for a rapid and simple method with no additional costly equipment. This is a preliminary report, but it seems this test works very well with fresh sera and, on the contrary, there is a lot of difficulties with sera that have been previously frozen. Apparently, sera can be shipped long distances unfrozen, at 4°C, without alteration of results.

T.B.P.141 EVALUATION OF LABORATORY PERFORMANCE OF ENZYME IMMUNOASSAY TESTS FOR HIV-1 ANTIBODY

Hearn, Thomas; Schalla, W.; Taylor, R.; Muir, H.; Griffin, C.; Wood, R.; and Valdiserri, R.
Centers for Disease Control, Atlanta, Georgia, U.S.A.

Objective. To evaluate laboratory performance of human immunodeficiency virus type 1 (HIV-1) antibody enzyme immunoassay (EIA) tests, the screening test primarily used in the United States to detect infection by HIV-1.
Methods. A panel of 22 samples was mailed in May 1988 to 1,309 laboratories enrolled in the Centers for Disease Control's Model Performance Evaluation Program (HIV-1 antibody testing is the specific application being used to develop this program.) The panels consisted of both single donor and pooled donor samples. Not all laboratories received the same 22 samples; 33 different lots of samples were actually used. All samples were provided in blind duplicates. The HIV-1 antibody reactivity levels varied from negative to weakly reactive to positive. In addition to providing sample analysis data, laboratories also provided information describing their laboratory and testing practices.
Results. Enzyme immunoassay results were reported by 1,201 laboratories; 48 percent were hospital laboratories, 18 percent blood banks, 16 percent independent laboratories, and 11 percent public health laboratories. Most of the laboratories (80 percent) reported only EIA test results; that is, they did not perform confirmatory testing. By manufacturer, 63 percent of the laboratories used a kit from Abbott; 9 percent used Genetic Systems; 9 percent, DuPont/Biotech; 8 percent, Organon; 6 percent, Ortho; and 4 percent, Electronucleonics. For the negative samples, the percentage correctly interpreted ranged from 74 percent to 100 percent and for the strong positive samples, from 98 to 100 percent.
Conclusion. Screening for HIV-1 antibodies is performed well by most laboratories in a variety of settings. Nonspecific matrix effects and weak HIV-1 antibody reactivity are the causes of some of the observed performance problems.

T.B.P.142 Results of CDC's Model Performance Evaluation Program for HIV-1 Antibody Testing

Taylor, Roger; Hearn, T.; Griffin, C.; Schalla, W.; Muir, H.
Centers for Disease Control, Atlanta, Georgia, USA.

Objective. To track trends in testing, to characterize HIV-1 testing laboratories and evaluate their performance, to document changes in performance and impact on public health, to evaluate emerging technology, and to identify possible sources of error and intervention strategies.
Methods. A combination of comprehensive demographic questionnaires and performance evaluation surveys were used to obtain lab descriptive data and test results. Questionnaires requesting information on lab type, personnel, workload, and testing procedures were mailed to labs in May and October 1988. Shipments of 22 samples per lab were mailed in February, May, and September of 1988. Results were tabulated and analyzed. Summary reports were returned to the participants.
Results. About 1400 laboratories are enrolled in this voluntary program. Both lab descriptive data and test results were usually provided by a high percentage of the labs (typically >90%). Enzyme immunoassay (EIA) results were reported by about 1200 laboratories; Western blot (WB) by about 250, and immunofluorescence by about 70. Results were compared by method and test manufacturer. Problems were identified with some commercial EIA kits with some samples. Need for standardization of WB test was apparent.
Conclusion. No serious performance problems were detected. Data will be used to develop a profile of labs which perform high quality testing. Continued operation of the program is required to monitor rapidly changing technology and applications.

T.B.P.143 CENTERS FOR DISEASE CONTROL MODEL PERFORMANCE EVALUATION PROGRAM: RESULTS OF THE WESTERN BLOT AND INDIRECT IMMUNOFLUORESCENCE TESTS FOR DETECTION OF HIV-1 ANTIBODIES

Schalla, William; Hearn, T.; Taylor, R.; Griffin, C.; Muir, H.; Wood, R. and Valdiserri, R.
Centers for Disease Control, Atlanta, Georgia, U.S.A.

Objective. To evaluate, through mailed sample panels, the performance of laboratories that test for human immunodeficiency virus type 1 (HIV-1) infection and to track changes or trends in Western blot (WB) and indirect immunofluorescence (IIF) testing through these periodic performance evaluations.
Methods. Panels containing 22 serum samples obtained from confirmed HIV-1 antibody-positive and antibody-negative donors were sent in May and September 1988 to the approximately 1,400 laboratories enrolled in a voluntary performance evaluation program.
Results. Among the 1,215 laboratories that returned results after testing the May performance panel samples, 229 (18.8%) and 71 (5.7%) laboratories reported WB and IIF results, respectively. Among the 1,185 laboratories that returned results after testing the September performance panel samples, 240 (20.2%) and 67 (5.6%) reported WB and IIF results, respectively. Eleven WB kits (commercial and in-house) were used by the laboratories in both surveys; whereas, 75% of the results were reported with five commercial kits. Six IIF kits (commercial and in-house) were used in both surveys. Little difficulty was demonstrated by the majority of the laboratories in reporting interpretations for the strong positive and true negative samples for the WB and IIF. Some laboratories reported viral specific bands for true negative samples; whereas, other laboratories reported negative interpretations for positive samples that contained viral specific bands. Some laboratories experienced difficulty in IIF result interpretation for samples that showed low reactivity in the enzyme immunoassay.
Conclusion. While no specific trends in WB or IIF were observed, the data suggested that future survey samples are needed for continued evaluation of laboratory performance.

T.B.P.144 *QUALITY CONTROL FOR ANTI HIV TESTING. THE EXPERIENCE OF ZAMBIA.*

Chinfwembe Evelyn C., Stahli C,** and Mukunyandela M,**
**Tropical Diseases Research Centre, Ndola, Zambia; **F Hoffmann-La Roche, Basle, Switzerland.*

Objective; The availability of various anti HIV commercial kits and the concern for valid results calls for the establishment of a panel of well defined sera for evaluation of test kits. For quality control purposes, a panel of sera was assayed for anti HIV using various kits in two laboratories.
Methods; Sera from 17 adult Zambian patients suspected to have AIDS were tested at Ndola, Zambia and Basle, Switzerland, for anti HIV. The following kits were used: Wellcozyme VK50/51 (Wellcome), Enzygnost-micro (Behring), Roche and HIV EIA and the Western Blot (W.B). An assay used to investigate the presence of peroxidase inhibitors, suggested by the Wellcome Research and Development Laboratory, was performed as a check on the Wellcozyme.
Results; Thirteen out of the 17 sera produced the same results in both laboratories on all the kits. The remaining 4 were repeatedly positive on the Wellcozyme in Ndola but negative in Basle, and negative on all other tests kits including the confirmatory test (W.B) in both laboratories.
Comments and Conclusion; The difference in results of the 4 sera may be due to (a) the presence of factors in sera that inhibit the peroxidase conjugate or (b) batch to batch variation of the peroxidase conjugate. It is suggested that (1) such discrepancies in results from biological kits may occur and require both internal and external quality control; (2) laboratories have a panel of well defined sera for the evaluation and monitoring of batch to batch variation of kits and reagents.

Pédiatrie : VIH
Pediatrics: HIV

T.B.P.145 PROBLEMS ENCOUNTERED IN HIV SEROLOGY

Major, Carol; McLaughlin, B. Ontario Ministry of Health, Toronto, Ontario, Canada.

Objective. With over 150,000 specimens submitted for HIV serology, we have encountered and described a number of difficult cases and situation which can lead to erroneous results and/or diagnosis.
Method. The problems ranged from simple specimen misidentification to complex situations including: the contamination of a negative serum by a minute quantity of positive serum (by submitting laboratories), carryover from positive to negative wells in the test procedure, detection of passive antibodies due to the administration of HIV seropositive immune globulin; interpretation of indeterminate results; cases of apparent sero-reversion, and failure of standard procedures to detect HIV antibodies in infected individuals.
Results. Mechanisms have been installed to detect the above mentioned situations, including: double verification of tube and requisition identification, requests for whole blood rather than serum samples, careful scrutiny of confirmatory test results for weakly-reactive or unusual results, justification of HIV results with clinical and risk group information provided by physicians and requests for follow-up specimens.
Conclusion. Laboratories must remain aware of the potential for erroneous results to occur and of the serious consequences of inaccurate results for the patient and the community at large.

T.B.P.146 ENHANCED CARDIAC FUNCTION IN PEDIATRIC HIV INFECTION.

Steven E. Lipshultz, Stephen P. Sanders, Steven D. Colan, Kenneth McIntosh. Children's Hospital, Boston, MA USA.

Objective. Fifty four pediatric patients with HIV infection underwent detailed, serial echocardiographic evaluation (n=133) of cardiac function as part of a natural history study. Methods. The M-mode shortening fraction was used to assess left ventricular (LV) function, end-systolic wall stress (ESWS) to measure afterload, and the relation between rate-adjusted velocity of fiber shortening and ESWS to evaluate contractility. This load-independent index allowed determination of contractility despite changing heart size and blood pressure. Results. At initial evaluation 50% of patients had hyperdynamic LV function, generally associated with enhanced contractility and reduced afterload. During follow-up of up to 57 months, function decreased to normal or subnormal in 69% of patients with hyperdynamic function initially. In contrast, function or contractility did not normalize in any patient presenting with reduced function and contractility. Hyperdynamic LV function was noted on one or more exams in 36 patients, irrespective of stage of disease or route of infection. This group included all patients with documented high-grade ectopy (n=4), sudden unexplained death (n=1) and 4/5 patients with evidence for cardiac or neural mononuclear infiltrate at autopsy. A change to enhanced LV function was observed in patients with previously normal function who developed mononuclear infiltrative disease of other organ systems. Unusual heart rate and blood pressure variability as well as exaggerated heart rate and blood pressure responses to medications were seen in these patients. These findings as well as autonomic function testing in selected patients are consistent with enhanced sympathetic tone. Conclusion. Hyperdynamic LV function is a common finding in early pediatric HIV infection, is often associated with autonomic instability and mononuclear infiltrative disease, and may be a marker for arrhythmia or sudden death.

T.B.P.147 MORTALITY IN CHILDREN WITH AIDS: AGE AT DIAGNOSIS AS RISK FACTOR

Iosub, Silvia; Bamji, M.; Stone, R.K.; Gromisch, D.S.; Wasserman, E.
New York Medical College, New York, USA.

Objective. To compare mortality in children diagnosed as AIDS in the first year of age (group I), vs those diagnosed above one year (group II).
Methods. The study was performed at two public hospitals in New York City on sixty two patients with perinatal HIV infection, admitted from 1984-1988 and followed for 1-50 months (mean 18 mo). All mothers except three were intravenous drug abusers. The majority of patients in group (G) I were symptomatic in the first six months of life. The G consisted of 42 patients, 14 blacks (b) and 28 Puerto Ricans (PR), 21 males (m) and 21 females (f). G II comprised 20 patients, 13 b and 7 PR, 12 m and 8 f, ranging in age from 12.5 to 72 months (mean 17 mo).
Results. Mortality was significantly higher in GI vs GII: 42% vs 5%, P=0.006. No significant sex and race differences were found in GI (52% mortality in f, 33% in m, 50% in b and 39% in PR), but mortality was higher in b f than b m (80% vs 33%). The majority of patients died of pneumocystis carinii pneumonia (PCP). In GII only 1 PR f died.
Conclusion. Infants with perinatal HIV infection who become symptomatic at an early age have a high mortality rate and females seem more at risk. Long term follow-up is needed to establish mortality rates in older infants and children.

T.B.P.148 ISOLATION OF HUMAN IMMUNODEFICIENCY VIRUS (HIV) FROM CEREBRAL TISSUE AND CHARACTERIZATION OF ITS BIOLOGICAL PROPERTIES

Dimitrov, D.H.; Gyorkey, F.; Hanson, I.; Melnick, J.L.; Shearer, W.; and Hollinger, F. Blaine.
Baylor College of Medicine, Houston, Texas, U.S.A.

Objective. To report the detection and isolation of HIV from the cerebral tissue of two perinatally infected children, 2 and 3 years old, with neurologic dysfunction.
Methods. Electron microscopy (EM), histology, and cell culture.
Results. Neuroradiographic evaluation of both children revealed marked cerebral atrophy. At postmortem examination, both brains showed encephalitis, cortical atrophy and decreased myelin. EM examination of the white matter of the brains revealed areas with myelin and cell degeneration. In these areas, infection of oligodendrocytes with HIV was inferred based on the presence of typical virion surface budding and HIV-like particles in the endoplasmic reticulum of these cells. Cocultures of normal donor PBMCs with 1 x 10^7 neural cells from these infected children yielded evidence of HIV infection as manifested by the expression of HIV p24 antigen in culture supernatants. These neural viral isolates readily infected T, B and monocyte cell lines, e.g. Jurkatt, MT-04, Raji, U937, HL-60 and THP-1, as determined by the detection of HIV p24 antigen in culture supernatants. The neural viral isolates were not cytotoxic for these cell lines.
Conclusion. These data suggest that HIV is associated with the neuropathology observed in the brain of infected children.

T.B.P.149 CUTANEOUS MANIFESTATIONS OF PEDIATRIC HUMAN IMMUNODEFICIENCY VIRUS INFECTION

Prose, Neil S.*
*State University of New York, Health Science Center at Brooklyn, Brooklyn, N.Y., U.S.A.

Objective To describe the varied cutaneous manifestations of HIV infection in children.
Methods One hundred and twenty-two children with HIV infection were examined as part of a dermatologic consultation service at three area hospitals. Skin biopsy and culture were performed as necessary.
Results We have developed an overview of the various cutaneous manifestations of pediatric HIV infection, and of the natural history of these disorders. There is no single cutaneous disease that is pathognomonic for HIV infection during childhood. The cutaneous manifestations of HIV disease in children are primarily fungal, bacterial, and viral infections. These include recalcitrant oral and cutaneous candidiasis, cellulitis, severe herpes simplex and herpes zoster, and unusual dermatophytoses. All of these manifestations are distinguished by their severity, frequency of recurrence, and poor treatment response. We have also seen patients with a severe atopic dermatitis, widespread flat warts, drug eruptions, chronic varicella-zoster infection, and unusual patterns of leukocytoclastic vasculitis.
Conclusion Familiarity with both the common and unusual patterns of cutaneous disease in the HIV-infected child can aid in early diagnosis, and in the treatment of opportunistic infections.

T.B.P.150 CLINICAL SPECTRUM OF HUMAN IMMUNODEFICIENCY INFECTION IN CHILDREN LESS THAN 4 MONTHS OF AGE.

Ellen R. Cooper, T. Schwartz, M.D. LeMay, A. Fine, S.I. Pelton, Boston City Hospital and Boston University School of Medicine, Boston, MA, U.S.A.

The early recognition of children with infection due to Human Immunodeficiency Virus (HIV) may permit intervention strategy such as nutritional supplementation, prophylactic antimicrobial therapy, or experimental antiretroviral therapies. We report on 11 HIV antibody positive (ELISA and Western Blot) who presented with clinical signs and symptoms before 4 mos. of age. The earliest diagnosis was made at 1 mo. of age in 1 child with thrombocytopenia at birth, who developed hepatosplenomegaly (HSM). 4 additional children presented before 2 mos. of life; 2 with proven PCP requiring mechanical ventilation, and 2 with axillary adenopathy and poor weight gain. 2 of the 11 children had the diagnosis established before 3 mos. of age; 1 with failure to thrive requiring nightly nasogastric tube feeding and axillary adenopathy, and 1 with developmental delay and presumed PCP. 4 of the 11 children presented before 4 mos. of age: HSM and lymphadenopathy (1), recurrent sepsis (1), suspected PCP pneumonia (1) and adenopathy (1) were the presenting signs. Of the 11 cases, 10 had mucocutaneous candidiasis by exam or history prior to 2 mos. of age, and 7 of the children had significant adenopathy at presentation. In 7 of the 10 children, IgG was already greater than normal. Ultrasound in 1 child revealed echo densities in the basal ganglia in the absence of neurologic findings. Children have been followed for a median of 6 mos. (range 1-46) since diagnosis. 3 of the 11 children developed a progressive encephalopathy resulting in death. All 3 were Haitian; illness in 2 of the 3 was complicated by infection with CMV, and none of the 3 had significant adenopathy.

T.B.P.151 HIV ACTIVATION BY COFACTORS: P-24 ANTIGENEMIA AFTER INJECTIONS OF SOLUBLE ANTIGENS IN CHILDREN WITH AIDS.

Samson,Johanne; Charest, J.; Pâquet, C. and Lapointe, N.
Hôpital Ste-Justine, Université de Montréal, Montréal, Québec, Canada.

OBJECTIVES: To monitor P-24 antigenemia (Ag) following repeated KLH injections and to correlate Ag with the clinical and immune status of patients.
METHODS: The study was conducted in HIV positive immunodeficient symptomatic children, asymptomatic adults, HIV negative children and adults. KLH was injected at 0 and 14 days. P-24 antigen (Abbott) was measured at 0, 14, 28 days and results were expressed after neutralization. Lymphocyte sub-populations, mitogen and KLH responses, anti-KLH antibodies by ELISA and PFC were measured at 0, 14, 28 days.
RESULTS: 29 individuals of which 13 were HIV positive were injected with KLH. P-24 Ag (units/ml) present in 3 of 10 children did not rise after injections. None of the 7 remaining children developed P-24 Ag. All met criteria for pediatric AIDS and were immunodeficient (mean T-cell:3384 ± 1946, CD4: 441 ± 462, CD8: 1037 ± 656), had depressed mitogen responses and no significant antibody responses to KLH. In asymptomatic HIV positive mothers, injections were associated with the appearance of P-24 Ag in 2 cases, and increase in P-24 Ag in 1 case. They had low normal T-cell count, low CD4 (9.7% ± 2.2)and CD8 (52.5% ± 9.1). Mitogen responses were generally normal, antibody response to KLH was partly abolished. No significant change in lymphocyte sub-populations was noted during the study.
CONCLUSION: Injection of soluble antigens may trigger P-24 antigenemia and this seems to be limited to asymptomatic moderately immunodeficient individuals. The clinical relevance of these findings requires further study.

T.B.P.153 PNEUMOCYSTIS CARINII PNEUMONITIS (PCP) IN CHILDREN WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV-1) INFECTION.

Scott, Gwendolyn, Reyes, J., Smith, L., Mastrucci, M. and Parks, W. University of Miami School of Medicine, Miami, Florida, U.S.A.

Objectives: To determine the clinical course and outcome of children with HIV-1 infection and PCP.
Methods: Hospital charts of 19 HIV-1 infected children diagnosed with PCP between January, 1983 and December, 1987 were retrospectively reviewed.
Results: Eighteen children had perinatally acquired HIV-1 infection and one acquired infection in the neonatal period through blood transfusion. There were eleven females and eight males. Seven of these children presented with PCP as their first manifestation of HIV infection. The median age of onset of PCP was 5 months with a range from 3-60 months. Diagnosis was made by demonstration of the organism in specimens from endotracheal aspirates (8), bronchoalveolar lavage (6), biopsy (4), and autopsy (1). Elevated IgG levels and depressed numbers of T helper cells were the most common immune abnormalities present at diagnosis of PCP. All children required oxygen therapy. Eight patients were intubated and received assisted ventilatory support for a mean time of 11 days. Median survival post-PCP was 10 months (range 1-53 months) for patients not requiring intubation and 1 month (range 1-11 months) in intubated patients. All but one of the children have died.
Conclusion: The early age of onset and the high mortality and morbidity associated with PCP in children emphasizes the importance of early recognition of infants at risk and indicates a role for PCP prophylaxis.

T.B.P.155 BRONCHO-ALVEOLAR LAVAGE TO EVALUATE PULMONARY STATUS IN THE HIV INFECTED CHILD.

Liliane BOCCON-GIBOD*, A SARDET**, A GRIMFELD**, J COSTIL**, C COURPOTIN*. Departments of Pathology*, Pediatric Pneumology**, Pediatrics*, and Intensive Care**. Hôpital Trousseau, Paris, France.

Bronchoalveolar lavage (BAL) is widely accepted in the adult AIDS patient. We have been among the first to initiate it's routine use in children.
Patients and Methods : Among 1500 pediatric BAL performed from 1981 to 1988, 79 concerned 50 HIV positive children (32 M, 18 F, aged 5 m to 12 y, 29 Blacks, 20 Caucasians, 1 Asian). Cases entered the following groups of the CDC Pediatric AIDS classification : P-2, Subclass A : 9, P2, Sub-class C (LIP) : 20, P2-Subclass D1 : 21, including 11 Pneumocystis Carinii (PC).
Results : BAL was fully successful in demonstration of pathogens : PC (11) CMV (6) mycobacteria (5) fungi (3) measles (1). High cellularity, high number of macrophages (Ma) and CD8 lymphocytes (Ly) per ml, increased spontaneous and stimulated H2O2 liberation by Ma are a constant feature of all groups. Opportunistic infections are associated with a high number of polymorphonuclears (PMN) never present in LIP. LIP's BAL profile is highly evocative : cellularity superior to controls (1100 x 10^3/ml vs 230 x 10^3/ml) as well as to others HIV cases (500 x 10^3/ml), elevated number of Ly (400 x 10^3/ml vs 20 x 10^3 in controls and 100 x 10^3 in other groups) absence of PMN are constant findings.
Conclusion : 1) BAL is efficient to investigate lung pathogens in children. 2) Active alveolitis is a constant finding in symptomatic HIV infected children (class P-2) regardless of pulmonary pathology. 3) LIP cases BAL profile is highly evocative of diagnosis

T.B.P.152 NATURAL HISTORY OF LYMPHOID INTERSTITIAL PNEUMONIA (LIP) IN PERINATAL HIV-1 INFECTION

Gray, Graciela, Scott, G., Castro A., Bradford, B.B., Mastrucci, M., Parks, W. University of Miami School of Medicine, Miami, FL, U.S.A.

Objective: To review the natural history of LIP in pediatric AIDS focusing on the clinical, radiological and immunological parameters.
Methods: From January 1981 to February 1988, 48 cases of LIP were diagnosed among 172 cases of perinatally HIV-1 infected children. Charts were reviewed retrospectively. X-rays were reviewed by the same radiologist. 100% of the children were black.
Results: Radiologically, LIP developed at a mean age of 16 months. Chronic lung disease with oxygen dependency and clubbing occurred in 20%. The reticulonodular pattern on chest x-rays cleared in 6%. Physical examination revealed lymphadenopathy 100%, hepatomegaly 98%, splenomegaly 83%, parotitis 73% and failure to thrive in 69%. Common infections were recurrent pneumonia 98%, Bacteremia 69%, recurrent otitis media 69% and recurrent diarrhea 50%. Opportunistic infections were less common. Mean level of IgG at onset of LIP was 4421 gm% (20 patients). AbsT4 levels at less than 1000/uL were seen in older patients at a mean age of 5 years. 10% died at a mean age of 34 months. Those who died often had concurrent opportunistic infections and significantly elevated IgG mean 6124 gm%.
Conclusion: LIP is often associated with lymphadenopathy, hepatosplenomegaly, failure to thrive, parotitis, recurrent pneumonia, bacteremia and recurrent otitis media. Opportunistic infections are rarely associated. Mortality is significantly decreased as compared to overall Pediatric AIDS mortality of 57%.

T.B.P.154 ADRENAL DYSFUNCTION IN PERINATAL HIV INFECTION.

Zacharski Eileen, Iosub S, Bamji M, Stone R, Pincus D, Noto R, New York Medical College; Valhalla, New York. N.Y.

OBJECTIVES: To study the hypothalamic-pituitary-adrenal axis in children with perinatal HIV infection.
METHODS: The study was performed at a public hospital in New York City on 12 patients aged 4 months to 7 years (mean=31.6 mos). There were 8 Hispanics, 4 blacks, 7 males and 5 females. All mothers were intravenous drug abusers. Laboratory evaluations included: baseline cortisol and ACTH, cortisol response to cortrosyn and overnight metopirone inhibition.
RESULTS:

	Baseline cortisol mcg/dl	ACTH-stim cortisol mcg/dl	Baseline ACTH pg/ml	Post-meto cortisol mcg/dl	Post-meto 11-deoxycortisol mcg/l
1.	17.1	28.7	>250000	16.3	17.3
2.	37.0	75.7	25	10.0	573.0
3.	7.7	39.2	11.0	10.9	70.5
4.	35.0	47.0	<10	28.3	97.0
5.	<2.6	41.2	13.0	3.3	144.5
6.	14.9	47.7	23.0	----	-----
7.	19.1	42.6	<10	27.0	128.0
8.	40.8	53.0	----	----	-----
9.	20.8	47.6	----	----	-----
10.	8.9	25.4	----	----	-----
11.	9.9	40.2	----	----	-----
12.	12.3	29.2	<10	13.7	pending

CONCLUSION: Though the majority of patients (72%) demonstrated normal adrenal function, a significant number (28%) had abnormal function manifested by a blunted response to ACTH, abnormal hypothalamic regulation or as yet unexplained elevated ACTH levels.

T.B.P.156 UNUSUAL MORTALITY FROM PNEUMOCYSTIS CARINII PNEUMONITIS (PCP) DURING EARLY INFANCY: PRIMARY, NOT REACTIVATION OF INFECTION?

Chow, Jean; Shah, K.; Li, K.; Gupta, A.; Chablani, V.; Kaul, A.; Gromisch, D.S. Department of Pediatrics, New York Medical College, New York, USA.

Objective. Is PCP in early infancy universally fatal? If so, what are the differences in the onset, course, and mortality compared to older children?
Methods. From 1984 to 1989, over 110 infants and children with HIV have been seen at 3 hospitals. PCP was confirmed in 15 children, from tracheal washings (3), lung biopsy (2), or at autopsy (11).
Results. 13/15 children were 6 months or younger. 13 previously healthy infants were thriving well. Associated physical findings included oral thrush (12), hepatosplenomegaly (10), generalized lymphadenopathy (7), and persistent fever (13). They presented with acute respiratory illness which rapidly progressed to respiratory failure. Course in older children was more protracted. Antimicrobial therapy with TMP/SMX and/or Pentamidine was initiated in 14/15 children. Despite early and aggressive therapy, 11/13 infants expired at first presentation. One surviving infant died at 11 months of age. Both of the older children are alive 1 and 2 years after PCP. Interestingly, lung biopsies in both the older children also showed lymphocytic interstitial pneumonitis (LIP).
Conclusion. PCP in early infancy can be a rapid and invariably fatal illness, primary infection, not reactivation of latent infection. Prospective studies of antimicrobial prophylaxis of PCP may show the greatest benefit in first year of life.

T.B.P.157 SEROPREVALENCE OF HIV INFECTION IN AN URBAN PEDIATRIC POPULATION

Luban, Naomi LC*; Josephs, SJ*; Getson, P;* Gayle, H.**
*Children's Hospital National Medical Center , George Washington University School of Medicine, Washington, DC and **Centers for Disease Control, Atlanta, Georgia, U.S.A.

Objective. To evaluate seroprevalence to HIV in children in a large, urban community with a high incidence of AIDS and drug abuse.
Methods. We conducted an anonymous, blinded serosurvey on discarded blood samples from children aged 2-8 years who presented to outpatient and community-based outreach clinics served by our pediatric teaching hospital between 1/87 and 12/88. Demographic information from the surveillance study was compared to that obtained on age-matched patients, who were HIV tested for clinical indications. Perinatally acquired HIV and sexually contracted disease was controlled for by limiting the enrollment age to 2 - 8 years, respectively.
Results. 4120 specimens were tested, 58% (2367) from males and 42% (1753) from females. The overall sample had a mean age of 4.79 ± 2.0 years. 4111 or 99.8% were nonreactive by EIA and 9 (.2%) were repeatedly reactive. Western blots confirmed 5 of the 9 EIAs for a seroprevalence of 1.2/1000; 3 were indeterminate, 1 was negative. All 5 blot positive specimens were from black children, age 2.2-8.6 years ($\bar{x} = 5.24 \pm 2.9$), 1 male and 4 females from 5 clustered zip codes, while the 3 indeterminants were from black males with an average age 4.95 ± 1.8 years. Although the Emergency Room (ER) accounted for 30% of total specimens, 63% of positive or indeterminate specimens were from the ER. There were no positive specimens (0/51) among age matched children tested for clinical indication during outpatient/ER visits during the same time interval.
Conclusion. HIV infection is present in 0.12% of urban children; a major source of identification is by presentation in the ER. Sequential analysis will define trends in the spread of HIV over time.

T.B.P.158 HIV INFECTION AND PEDIATRIC AIDS IN SEMI-RURAL DABOU PROTESTANT HOSPITAL (IVORY COAST)

L. Schuerman*, V. Seynhaeve*, A. Ouattara**, G. de Thé***
* Protestant Hospital, Dabou, Ivdry Coast ** Pasteur Institute , Abidjan, Ivory Coast *** CNRS Lab Faculty Medicine Alexis Carrel, Lyon, France

Within a year (Feb 87-Jan 88), 293 suspected cases of pediatric AIDS based on Bangui criteria and/or with severe malnutrition were tested for HIV-1 and HIV-2 by ELISA and then western blot. 75 (25.6%) had confirmed antibodies to HIV: 63 (21.5%) exhibiting HIV-1 reactivity, 4 (1.4%) HIV-2 reactivity and 8 (2.7%) double reactivity. No difference in symptom frequency was observed between these sub-groups.

Mothers of 68 positive children were also tested. In 48 cases (71%) , the child infection probably originated from seropositive mother ; in further 10 cases the mothers were positive but the children were transfused, so the origin of infection remained problematic ; in 4 children, the origin of infection remained unknown as their mothers were seronegative and the children did not receive transfusion.

The study of 100 sequential cases of pediatric severe malnutrition showed 14 cases of HIV positivity: 11 HIV-1, 2 HIV-2 and 1 HIV-1+2. The testing of 95 corresponding mothers showed that 19 were positive (12 having a seropositive child, but 7 a seronegative one). Two children with seronegative mothers had been contaminated by blood transfusion.

Among 83 HIV positive children, 11 died during hospitalization, 14 were moribond at their discharge from hospital and 19 could be followed-up. Among those, one died within 10 months after diagnosis, 4 had an unfavorable evolution, but 14 exhibited improvement during a follow-up period of 3 to 6 months.

T.B.P.159 MATERNAL DRUG ABUSE AND PERINATAL HIV SEROPOSITIVITY

Checola, R.T., Hand I., Wiznia, Andrew, Kim, M., Noble, L. Yoon, J. Albert Einstein College of Medicine, Bronx, N.Y. USA

Objective. Assess the prevalence of HIV seropositivity (+) in infants of drug abusing mothers (IDAM) delivered at Bronx-Lebanon Hospital.
Methods. In a six month period in 1988, HIV antibody was studied by Elisa and confirmed by Western blot in 101 IDAM with maternal consent. All infants were examined and maternal and neonatal data were compared in the HIV+, HIV- infants and non IDAM control infants.
Results. In 1982, 3.1% of newborns were IDAM (75/2437) compared to 12.8% (365/2806) in 1988, (p <.0001). A 19.8% (20/101) incidence of HIV+ was higher than a 6% (5/84) in the non IDAM normal newborns (p <.01). As expected, the HIV (+) rate was higher in the 15 IV IDAM than the 86 non IV IDAM (50% vs 14%) (p<.001). There were no significant differences in race, maternal age or mode of delivery in the HIV+ and HIV- groups. Lack of prenatal care was similar as was the incidence of maternal syphillis. Maternal smoking, alcohol and drug used were also similar in these groups. Gestational age (37.5 vs 37.5) birth weight (2394 vs 2458), LBW rate (60% vs 53%) and SGA infants (30% vs 16%) and microcephaly (HC<10%: 20% vs 11.1%) were not significantly different in the above groups, though they differed from the general population (p<.001).
Conclusion. No neonatal factor were identified which could be attributed to HIV seropositivity. Decreased GA and BW and increased incidences of LBW, SGA, and microcephaly may be due to maternal drug abuse, not HIV. Maternal IV drug abuse is a significant risk factor for HIV seropositivity. However, 60% of HIV mothers did not have any history of IV drug abuse. This suggests that heterosexual contact plays a significant role in the HIV transmission.

T.B.P.160 DIFFICULTIES ENCOUNTERED IN INFORMING THE PARENTS OF NEWBORNS OF HIV TESTING RESULTS IN AN URBAN COMMUNITY.

Wiznia Andrew, Caffrey BC, Checola R, Thorpe A, Daley T, Caspe, W.B. Bronx-Lebanon Hospital Center, Bronx, New York. U.S.A.

Objective: To evaluate maternal compliance in infants at risk for HIV infection.
Methods: Bronx Lebanon is located in the South Bronx, an area highly endemic for HIV infection (4-5% of pregnant women are HIV infected). Maternal consent is routinely sought to screen newborns whose mothers had identified risk factors for HIV. An appointment is scheduled for two weeks later to discuss the test results. Missed appointments are pursued by telephone calls and certified letters. Older children at risk, identified during hospitalizations, well child care or from outside sources are also screened with parental consent. All identified children are to be followed in an immunology clinic.
Results: Appointments to receive testing results were attended by only 32 of 114 mothers. These include 29 (29%) of the 101 HIV negative newborns and 3 of 13 (23%) infants with positive HIV serology in spite of multiple attempts to contact these mothers. In contrast, 21 of 23 (90%) of the older HIV infected children have been compliant with medical follow-up.
Conclusion: In this urban community, the rate of success in communicating HIV testing results to mothers of neonates is poor once that infant is discharged in spite of the mothers granting informed consent. A more rapid reporting of results and informing the mother prior to discharge may improve compliance with medical follow-up.

T.B.P.161 CLINICAL & IMMUNOLOGIC FEATURES ASSOCIATED WITH PEDIATRIC HIV INFECTION IN LOS ANGELES COUNTY, CALIF.

Frederick, Toni*; Mascola, L.*; Beene, M.*; Church, J.**Bryson, Y.***; Kovacs, A.**; et al
*Los Angeles County Health, Dept. of Health Services;
**University of Southern California;
***University of California Los Angeles, L.A, Calif., USA.

Objectives. To gain insight into the clinical and immunologic spectrum of pediatric HIV infection using data from a Los Angeles County (LAC) active surveillance program.
Methods. An active surveillance system for cases of pediatric HIV infection began in 3/88. Using clinical and lab data from medical records, HIV infected children were classified using the latest CDC classification system and according to whether they had immunologic abnormalities.
Results. As of 12/30/88, LAC had 139 cases of pediatric HIV infection. Fifty (36%) had AIDS, 38 (27%) had symptoms but not AIDS, 33 (24%) were asymptomatic, and 18 (13%) were indeterminant (children <15 mos. without virologic evidence of infection). About half of these cases (excluding the indeterminants) had immunologic data available. AIDS and non-AIDS cases differed on all immunologic features. Among the AIDS cases, 76% had a T4 cell count $<400/mm^3$, 100% had a T4/T8 ratio <1.0, 60% had a lymphocyte count $<3000/mm^3$, and 46% had a total serum immunoglobulin level >2500 mg/dl. Although less prominent, many non-AIDS cases had abnormalities as well; 66% had abnormal T4/T8 ratios, 38% had increased immunoglobulins, 23% had abnormal T4 counts, and 7% had abnormal lymphocyte counts.
Conclusion. The spectrum of clinical illness and immunologic abnormalities among HIV infected children is great. Continued surveillance and follow up will better define the natural history of HIV infection in children with regard to clinical and laboratory parameters.

T.B.P.162 NEWARK PERINATAL COHORT NATURAL HISTORY PROGRESS REPORT.

Connor, Ed.*, Schneck,M, Denny, T.*, Oxtaby, M.,**Ou, C.Y.**, Oleske, J.*, et al,Children's Hospital of NJ & UMD-NJ Medical School Newark NJ* & Centers for Disease Control, Atlanta GA** USA.

Objective. In 3/87 a study of infants (INF) born to HIV infected mothers (M) at a large hospital in Newark was initiated to define the rate of perinatal transmission of HIV and the natural history of these INF.
Methods. HIV+ M who delivered INF are invited to participate. INF are prospectively monitored every month x6mo, then every 2mo x6 mo, and every three months thereafter. Clinical, immunologic, serologic and retrovirologic data are collected at specified intervals.
Results. Forty seven INF born to 44 M were enrolled 3/87-1/89. Mean age of M = 29.7 yr (16-38); 93% black, 5% hispanic, 3% white; 80% were IV drug users and 20% acquired HIV by sexual contact. At delivery 84% were asymptomatic, 10% ARC and 10% AIDS. Mean gestational of INF = 36.5 wk (29-40); 19 were <36 wks and 6 were SGA. There were 29 INF that were followed for >9 mo. Five INF were considered HIV infected: 3/5 had +HIV cultures, 2/3 had HIV symptoms and died at 5&7 mo, 3/3 had +PCR; 2/5 had +P 24 Ag CSF, both are well and one had +PCR and 1 + PCR. Of the remaining 24 INF, 8 are considered non-infected while 16 are well but indeterminant. One of these infants died at 2 mo of complications of prematurity. Seven of 8 PCR assays on this group were negative and one positive at 15 mo on a presumed non-infected 17 mo INF.
Conclusions. While it is premature to determine transmission rate, it is significant that 93% of INF in this cohort followed >9mo have remained asymptomatic. In general there was concordance between PCR and other parameters of infection.

T.B.P.163

44 HIV-EXPOSED NEWBORNS - CLINICAL, VIROLOGICAL, AND IMMUNOLOGICAL FOLLOW-UP.

Carla Rosendahl, U. Wintergerst, R. Lutz, D.H. Belohradsky.
Immunodeficiency clinic, University Hospitals for Sick Children, Munich, W-Germany.

Objective. Since 1984 infants and children with typical HIV-associated symptoms are cared for in Munich's University Children's Hospitals. Until now 44 newborns with intrauterine/perinatal HIV-exposition only from Bavaria are followed up in a national multicenter study. The aim of this investigation is to define the transmission rate from mother to child, the factors influencing manifestations of AIDS, and to evaluate the benefit of prophylaxis and therapy with immunoglobulins and zidovudine.

Methods. Infants are followed up in intervals of three months beginning at delivery. In addition to maternal HIV-antibody-status, we try to accumulate further virological and immunological data of the mother as they occur during pregnancy. Children with proven HIV-infection receive monthly infusions of standard-immunoglobulin in a dose of 400 mg/kg bw. Those with full blown AIDS are treated with immunoglobulin plus oral zidovudine (3,5 mg/kg bw qid).

Results. Data of the mother's pregnancy are available for 15 out of the 44 children. Four mothers had definitive viremic episodes (p24- antigen, virus-isolation) during pregnancy. Of all others only HIV-Ab-positivity was known. 15 children lost their HIV-antibodies and remained clinically and immunologically healthy. In 15 other children the HIV-infection could be confirmed. 5 of them died of AIDS, 7 receive prophylactic immunoglobulin-infusions, 3 are treated with immunoglobulines plus zidovudine (Retrovir^R). Two of the zidovudine-recipients had neurological symptoms which improved upon therapy. The third child fell ill with a pneumocystis carinii pneumonia which could successfully be treated. In 14 children, younger than 15 months of age and HIV-Ab-positive, HIV-infection could not be ascertained so far. Clinical symptoms, virological results and immunological parameters of all patients will be presented in detail.

Conclusion. With cautious interpretation of our data the transmission rate is 40 %. A suspected correlation between proven viremia during pregnancy and HIV-transmission to the child should be confirmed by more frequent virological tests of the mother during her pregnancy. Infants with confirmed HIV-infection may benefit of the immunoglobulin-prophylaxis since this medication seems to suppress bacterial and viral infections and possibly decreases HIV-replication. Immunological parameters could not be influenced by this therapy.

T.B.P.164

EVOLUTION OF A SERIE OF 23 CHILDREN SEROPOSITIVES TO HIV.

Pablo MFontelos, MJ.Cilleruelo, MJ.Mellado, J.Villota, M.García, G.Barreiro, Instituto Carlos III, S. Pediatría, Madrid, SPAIN.

MATERIAL AND METHODS: We present 23 children, 13 males and 10 females, whose ages range from 7 days to 11 years old. In 2 cases, the infection was acquired through blood transfusion. The other 21 children were infected from 19 mothers with positive HIV antibodies. Only 17 mothers wereDAVP and the other 2 acquired the infection by heterosexual contact. We determinate HIV antibody by ELISA, IFI and W.blot and Ag P_{24} by capture ELISA methods. The follow up varied from 2 to 16 month.

RESULTS: In accordance with CDC classification, the children are included: 10 in Po class, 3 in P_1 class and 10 in P_2 clas. Among the 21 cases infected through their mothers, in 4(19%) the HIV antibody have become negative before reaching 15 month old. Seventeen of them (81%) persist with positive HIV antibodies, and 10 of the 17 show sympthoms. Only 1 of 3 children included in P_1 class shows immunological alte ration. All of the 10 sympthomatic cases are receiving treatment with gammaglobu lin and antibiotics prophylactically to reduce recurrent infections, and 8 of them are receiving Zidovudine also. Clinical evolution is favourable in 62% of the ca ses and stationary in the rest. Only 1 child has died because of a pneumonia caused by Adenovirus.

CONCLUSIONS: 1) In our serie, the persistence of positive antibodies in children over 15 months old who were infected by their mothers is 81%. 2) In contrast to other adult studies, in our cases only 13% of the infected children are asym-pthomatic. 3) Our mortality rate is 4.5%. 4) Despite of having become negative HIV antibodies in serum, it's necessary to maintain a close watch on these children to exclude HIV infection definitively.

T.B.P.165

NATURAL HISTORY OF PEDIATRIC HIV INFECTION

Giaquinto, Carlo; DeRossi A*; Girotto S; Cozzani S; D'Elia R; * Chieco-Bianchi L et al.
Department of Pediatrics, *Institute of Oncology, University of Padova, Italy.

Objective: To investigate the natural history of HIV infection in children born to seropositive mothers.

Methods: Children born to HIV positive mothers in high risk groups were evaluated clinically, serologically and virologically every two months. Neuromotor assessment and evaluation of mental development were also performed.

Results: 104 children have been studied over the last 4 years. 91 were born to IVDA mother, 6 to partner of IVDA. 46 children, negative for virus who became seronegative (mean age 11.5, range 6-18) were classified as not infected. Using CDC criteria 30 children resulted infected: 2, positive both for viral culture and PCR, became seronegative and are clinically and immunologically well. 28 were "indeterminate". Considering only the 63 children followed up from birth and older than 15 months, the prevalence of HIV infection is 23.8%. 9 out of the 15 infected children (60%) followed up from birth developed symptoms, all of them in the first year of life; 4 died of AIDS. Hypergammaglobulinemia and T4/T8 ratio<1 were found in all but 2 symptomatic children (one of whom had hypogammaglobulinemia and the other died of AIDS at 4 months). 5 of the 7 children showed immunological alterations before the onset of any symptom. All but one asymptomatic children do not show any immunological alteration.

T.B.P.166

HUMAN IMMUNODEFICIENCY VIRUS-1 (HIV-1) INFECTED INFANTS: ASSOCIATION OF LABORATORY PARAMETERS AND CLINICAL OUTCOME.

Butto, C., Scott, Gwendolyn, Lai, S., Mastrucci, M., and Parks, W. University of Miami, Miami, FL.

Objectives: To determine the rate of HIV-1 maternal to infant transmission in a population-based prospective study, and to assess factors predictive of clinical outcome in infants born to HIV-1 seropositive mothers. Methods: The infection status of 60 infants was determined by virus isolation and comparison of HIV-1 antibody titers from sequentially collected sera. Virologic, immunologic, and clinical data from uninfected and infected infants of seropositive women and offspring of matched seronegative controls were compared using logistic and multiple regression analysis for factors predictive of outcome. Results: Twenty of 60 (33%) infants are HIV-1 infected by virus culture (19) or persistent antibody (1). The mean enrollment age for infected (5.5 mo.) and uninfected infants (5.1 mo) was similar. Comparison of mean birth wgt., gestational age, and initial hemoglobin, absolute lymphocyte #, CD11, CD8, CD4, CD4/CD8 ratio, IgG, IgA, IgM, and antibody titers found significant differences between the 2 groups for absolute lymphocyte #, CD11, CD4, IgG, and IgA. All HIV-1 infected infants had immunologic abnormalities and 10/14 (70%) had clinical disease by 18 mo. of age. Median followup of the 40 uninfected infants was 11.5 months (range 5-24). All uninfected infants of seropositive mothers were clinically and immunologically similar to age-matched controls. Conclusion: Positive viral cultures, persistent HIV-1 antibody, abnormal levels of IgG and low CD4 counts are associated with infection and clinical disease in infants born to HIV-1 infected mothers.

T.B.P.167

SEVEN YEAR FOLLOW-UP OF HIV INFECTION IN NEONATAL TRANSFUSION RECIPIENTS

Thomas M. Mundy*, L Lieb**, J Ward***, F Allen*, M Oxtoby***, J Faust*, M Bick*.
*Amie Karen Laboratories, Cedars-Sinai Medical Center, **L.A. County Department of Health, Los Angeles, CA, ***AIDS Program, Centers for Disease Control, Atlanta, GA.

Objective. To extend the observations on the natural history of HIV infection in a cohort of neonatal transfusion recipients now 6-9 years of age.

Methods. The cohort consists of 39 children infected with HIV through transfusions as neonates.

Results. 13/39(33%) children died at a mean age of 50 mo; 26/39 (67%) children are alive at a mean age of 84 mo. Of the 26 living children, 17 are asymptomatic meeting the following CDC classifications: P1A=11 patients, P1B=6. The remaining 9 are symptomatic, classified P2A=6, P2C=1, P2D=2. Thus, 44% of our cohort of children infected through transfusion as neonates remain asymptomatic at a mean of 7 years although 1/3 of them are severely immunocompromised. An additional 18% have non-specific symptoms and only 8% have had opportunistic infections or lymphoid interstitial pneumonitis. The mean age of both the symptomatic and asymptomatic groups is 84 months.

Conclusion. In our 7th year of follow-up, AIDS has developed in 8% and severe immunologic deterioration occurred in 13% of our seropositive patients. Still, 44% of children infected with HIV through transfusion as neonates remain asymptomatic at a mean of 7 years.

T.B.P.168

CLINICAL CHARACTERISTICS OF PEDIATRIC AIDS BELOW AND ABOVE ONE YEAR OF AGE

Iosub, Silvia; Bamji, M.; Stone, R.K.; Gromisch, D.S.; Wasserman, E.
New York Medical College, New York, USA.

Objective. To compare the clinical features of children who became symptomatic and were diagnosed as AIDS below one year (group I) vs those above one year of age (group II).

Methods. The study was performed at two public hospitals in New York City on sixty two patients with perinatal HIV infection, admitted from 1984-1988 and followed for 1-50 months (mean 18 mo). All mothers except three were intravenous drug abusers. Group (G) I comprised 42 infants, 14 blacks (b) and 28 Puerto Ricans (PR), 21 males (m) and 21 females (f). The majority became symptomatic in the first 6 months of life. G II consisted of 20 patients, 13 b and 7 PR, 12 m and 8 f, ranging in age from 12.5 months to 72 months (mean 17 mo). Features compared included: lymphadenopathy, failure to thrive (FTT), pneumocystis carinii pneumonia (PCP), lymphoid interstitial pneumonia (LIP), recurrent infections, hepatosplenomegaly, persistent mucocutaneous candidiasis, dermatitis (seborrheic or atopic), chronic parotid swelling, opportunistic infections, CNS abnormalities, nephropathy and cardiopathy.

Results. PCP and candidiasis were significantly more frequent in GI than II: 42% vs 5% resp 50% vs 10%, P=0.005. LIP and chronic parotid swelling were more frequent in GII than I (65% vs 47% resp 10% vs 2%). There were no significant sex or race differences between groups. In GII FTT was significantly more frequent in m vs f (66% vs 12%, P=0.02).

Conclusion. The very young infant has the same clinical manifestations of AIDS as the older one, except that PCP and persistent mucocutaneous candidiasis are more frequent in the former and LIP in the latter.

T.B.P.169 NATURAL HISTORY OF PEDIATRIC AIDS, 1988

Frenkel, Lawrence D.; Gaur, S.; Kesarwala, H. and Scudder, R.
UMDNJ-Robert Wood Johnson Med. Sch., New Brunswick, NJ, USA.

Objective. To assess mortality data as it relates to pattern of initial presentation among symptomatic HIV infected children.
Methods. The Central New Jersey Pediatric AIDS Group has followed 65 infants and children born to HIV infected mothers, since 1983; 29 of these were in the CDC-P_2 category and represent almost 50 child years of followup. Thirteen symptomatic (P_2) children were enrolled into an open IVIG therapeutic trial.
Results. Recognition of maternal HIV antibody positivity at, or prior to, delivery occurred in only 5 infants. The presentation patterns of the symptomatically HIV infected children are summarized below:

Pattern of Presentation	Number	Mean Age at Diagnosis	Mortality	Mean Age Currently	Mean Age at Death
Overwhelming Pneumonitis prior to 6 mo. of age	9	4 (mo.)	67%	12 (mo.)	6 (mo.)
Failure to thrive, opportunistic infections	12	7 (mo.)	58%	27 (mo.)	19 (mo.)
Lymphoid interstitial pneumonitis	7	19 (mo.)	15%	58 (mo.)	75 (mo.)
Thrombocytopenia purpura	1	4 (mo.)	0%	28 (mo.)	-

In the IVIG treated group, mortality was 38%, and in the untreated group 56%. The median overall survival time of all P_2 children is 75 months but only 9 months for those infants presenting with overwhelming pneumonitis. Five out of six of the infants who died were infected with PCP or CMV or both.
Conclusion. Potential benefit of early diagnosis and preventive therapy among children acutely presenting with overwhelming pneumonitis needs evaluation.

T.B.P.170 HIV INFECTION IN CHILDREN: PRONOSTIC FACTORS FOR THE PROGRESSION OF THE DISEASE.

A.M. Duliège*,S. Blanche*,M. Tardieu**,C. Rouzioux**,A Messiah*, C. Griscelli*.
Hôp. Bicêtre: U292*; U56**; Hôp. Necker: paediatric immunology*;virology**;Paris, France.

- Some infected children have a rapid evolution. We determine the clinical outcomes related to an early death. We look whether the 1° biological tests have a pronostic value on these outcomes.
- 94 HIV1 infected children all born to HIV positive mothers were followed at Necker Hospital (Paris). They were referred because of HIV related symptoms (P2A in 75% of the cases) at a median age of 10 months. The 1° biological check-up was performed at the time of the 1° visit. The median follow-up at Necker is 15 months; 4 children are lost to follow-up. A Cox model and a Log-rank test have been used for the multivariate analyses.
- clinical outcomes related to an early death: a lymphocytic pneumonia or a bacterial infection are not related; an opportunistic infection (OI) and a severe encephalopathie (Enc.) are:

	nb	age at outbr. (median)	% survival at 3 years (±SD) if event present	absent	p
IO	28	7	40 (±12)	97 (±1.5)	< .001
Enc.	16	9	32 (±14)	92 (±3)	< .001

Both events are also closely related to each other. The 28 children (30%) with an IO and/or an Enc. have a much higher risk of dying rapidly than the others.

biological check-up performed at 1° visit; the pronostic tests on these outcomes are:

- a T4 cells count below 500/mm3	RR = 6.1 [2.1-18]
- the absence of antibody against HIV p25 and/or p18	RR= 5.5 [1.8-16]

The in-vitro proliferation of lymphocytes is closely related to the previous tests.
- In conclusion, the first biological check-up of symptomatic children yields strong prognostic information, leading to discriminate early in life the group of children characterized by a more rapid progression.

T.B.P.171

T.B.P.172 LONGITUDINAL EVALUATION OF IMMUNOLOGIC AND VIRAL MARKERS OF HIV INFECTION IN CHILDREN :CLINICAL CORRELATION.

*T.HERNANDEZ-SAMPELAYO; L.PEREZ ALVAREZ;*M.D.GURBINDO; L.MUÑOZ;*J.FERMOSEL; C.CASADO et Al.
INSTITUTO DE SALUD CARLOS III: UNIDAD DE SIDA; *H.GRAL.GREGORIO MARAÑON, MADRID,SPAIN.

Objective.To determine the proportion of HIV infected newborn to HIV Ab+newborn and define changes of immunologic and viral markers that correlate with disease stage,to determine predictive pronostic markers of HIV infection in children.
Methods.We studied 35 HIV+ children born to HIV+ drug abuser mothers,ELISA(EIA) WESTERN BLOT(WB) 19 males and 16 females,from birth to present age. 24,6 months (4-61).Analytical determinations were done every 3-6 months.Specific antibodies for HIV have been measured by EIA and WB assays: HIV P-24 antigen has been measured by EIA;viral isolation has been attempted by co-culturing peripheral blood mononuclear cell (PBMC). CD4 and CD8 were also measured.Clinical stage was evaluated.
Results.Actuarial curve of negative seroconversion of HIV Ab stabilized about 50% after 21 months of age.Thirteen out of 35 children became seronegative between 9 and 21 months of age. 5 out ofthe 13 children after 15 months old.At present,14 out of 22 seropositive children are included into P2 clinical stage.Children into P0 stage showed P-24 Ag and co-culturing PBMC negatives while the 50% of children in P-2 stage showed positive P-24 Ag and 33% co-culturing PBMC positive.Decrease CD4 counts and CD4/CD8 rate were found in P1 and P2 stages.
Conclusion.Some children may become seronegative after 15 months of age.P-24 Ag and viral isolation demonstrated high specifity.The detection of P-24 Ag correlated with advanced clinical and immunological stage of HIV infection.

T.B.P.173 LONG-TERM FOLLOW-UP OF INFANTS BORN TO INTRAVENOUS DRUG USERS OF KNOWN HIV SEROSTATUS IN THE BRONX, N.Y.: CLINICAL & LAB PARAMETERS

Mayers Marguerite*, Davenny K*, Schoenbaum EE*, Feingold A*, Selwyn P*, Rogers M** et al.*Montefiore Med. Ctr., Bronx, N.Y. and **CDC, Atlanta, GA, USA.

Objective: To study the natural history of HIV infection in infants born to HIV seropositive (HIV+) and seronegative (HIV-) intravenous drug users.
Methods: Sixty-one infants of women attending a methadone maintenance program participated in a long-term HIV natural history study and had serial tests of HIV antibody (Ab), viral culture (Cx), p24 antigen (Ag), T-cell subsets, PCR, physical exams, and were monitored for clinical illness, growth and development.
Results: Median follow up was 80wks for 31 infants of HIV+ mothers and 73wks for 30 infants of HIV- mothers (range: birth to 162 wks).

Table: Clinical Status and Lab Results of Infants of HIV+ Mothers at Last Follow Up

		n	Ab+	p24 Ag+	Cx+	PCR+	mean T4	mean T4/T8
Asymptomatic (ASX)		23	7/23	1/16	0/10	0/10	2987	2.04
HIV-Related Illness	(SX)	5	2/5	1/4	0/2	0/3	980	1.70
AIDS		3	2/3	2/3	2/3	3/3	881	1.26

Of SX infants, 4/8 (50%) had lost Ab by 69 wks, while 16/23 (70%) ASX infants had lost Ab (Western Blot) by 77wks. SX infants presented with clinical illness at a mean age of 25 wks. Six of eight mothers of SX infants vs 8/23 mothers of ASX infants were CDC class III or IVC2 at delivery, and had 3rd trimester T4/T8 ratios <1.0 (p<.01). Upper respiratory infection, otitis media and gastroenteritis occurred with equal frequency in infants of HIV+ and HIV- mothers.
Conclusion: Infants who developed AIDS had lab evidence of infection. Lab studies did not distinguish ASX infants from those with non-AIDS HIV-related illness, making clinical assessment over time the strongest indication of HIV infection.

T.B.P.174 EARLY CNS SIGNS IN INFANTS WITH PERINATALLY-ACQUIRED HIV INFECTION.

Anita L. Belman,* Park Y* Diamond G* Nozyce M* Douglas C* Cabot T* et al. SUNY @ Stony Brook,* AECOM,N.Y.

Objective: Identify early manifestations and progression of HIV-related CNS involvement in infants with perinatally-acquired HIV infection.
Methods: Prospective study of infants born to HIV+ women. Controls are infants born to high risk but HIV- women (IVDA, substance abusers or sexual partners of HIV+ or IVDA males). Standard neurologic examinations and Bayley Scales of Infant Development (BSID) are adminstered at 3 month intervals.
Results: Currently, 19 infants are in the HIV+ group; 25 in the control group. In the HIV+ group 9 are >1 yr of age (13-24m). Four have variable degrees of CNS dysfunction manifested by poor head control, abnormalities of tone & reflexes, deviations from the normal rate of acquisition of developmental milestones &/or declining scores on the the BSID. No infant has lost milestones. Five have normal neurologic exams. Of the HIV+ infants <1 yr. of age, 4 have abnormal exams (6-11m). In the control group, 18 are >1 yr. of age (12-20m); 1 is delayed & 1 had motor findings. Of the 7 <1 yr, (7-11m), 3 have abnormal exams. Varying degrees of irritability, tremulousness & tonal abnormalities were noted in the neonatal period in both groups; this may reflect in utero drug exposure.
Conclusion: Infants with congenital HIV infection may manifest early CNS dysfunction. Signs are frequently subtle and may occur prior to or concomitant with systemic illness. In this series 42% of HIV+ infants were affected compared to 20% of controls. As more infants are enrolled into the study longitudinal follow-up with correlation of neuroimaging, neurophysiologic, virologic and immunologic status, should help determine the eventual neurologic course (static, plateau or progressive) and factor(s) predictive of progressive CNS disease.

T.B.P.175

BEHAVIORAL CHANGES IN CHILDREN WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION. Lifschitz, Marta; Hanson, C.; Wilson, G. and Shearer, W.T., Baylor Col. of Med., Houston, Tx, USA.

Objective. Common neurological manifestations in HIV-infected children include acquired microcephaly, developmental delay, and pyramidal tract signs. This is a report of behavioral changes in two HIV-infected girls.
Method. Longitudinal assessment included complete immunological profile, head imaging by CT scan or MRI, and neurodevelopmental examinations.

Results.	Patient #1	Patient #2
Age last evaluation	4 4/12 year	5 7/12 year
Source, HIV stage	Transfusion, P-1 A	Maternal, P-1 A
Serology	(+) EIA, W. Blot	(+) EIA, W. Blot
IgG, mg/dL	2420	2850
Head imaging	Normal	Normal
McCarthy GCI score	97	90

The neurodevelopment of patient #1 was consistently average but she had onset of behavioral problems at age 3½ yrs. A conduct disorder as per DSM-III R criteria was diagnosed based on fire-setting x 4, deliberate destruction of other's property, and physical abuse to people. Patient #2 showed delayed development at 3 yrs., however, at 5 7/12 yrs. intellectual functioning was low average with a deficit in visual-motor-perception. Distractibility was first noted after 3 yrs. and has progressed to attention deficit hyperactivity disorder (ADHD by DSM-III R) responsive to Ritalin.
Conclusion. Behavioral dysfunction in children with HIV infection may be an early manifestation of CNS involvement. These preliminary observations may be relevant for treatment planning and indicate the need for inclusion of systematic behavioral along with neurodevelopmental assessment.

T.B.P.177

AIDS-RELATED PERIPHERAL NEUROPATHY IN CHILDREN AND YOUNG ADULT HEMOPHILIACS

Koch, Thomas*; Wesley, A.*; Lewis, E.*; Bredesen, D.*; Koerper, M.⁺; Weintraub, P.⁺; et al.
Departments of Neurology* and Pediatrics⁺, University of California, San Francisco, CA USA.

Objective: To assess the occurrence of peripheral neuropathy in HIV positive children and young adult hemophiliacs.
Methods: A cross sectional study was conducted. Nineteen infants and children and 8 young adult hemophiliacs, all HIV positive were examined by a pediatric neurologist for clinical evidence of a peripheral neuropathy. Seven of the children , all on an AZT protocol, and 2 of the hemophiliacs had clinical AIDS.
Results: No clinical signs or symptoms of peripheral involvement were seen in any of the 27 patients (additionally, electrodiagnostic studies (EMG/NCV) were performed on two of the children and were normal).
Conclusion: The absence of a peripheral neuropathy in children and young adult hemophiliacs contrasts greatly with its occurrence in 35% of adult homosexual AIDS patients. This lack of neuropathy correlates with the absence of a specific autoantibody described in patients with HIV-related peripheral neuropathy (accompanying abstract).

T.B.P.179

NEUROPSYCHOLOGICAL PROFILE OF CHILDREN WITH SYMPTOMATIC HIV INFECTION PRIOR TO ANTI-RETROVIRAL TREATMENT.

Brouwers, Pim, Moss, H., Wolters, P., Eddy, J., Pizzo, P. Pediatric Branch, National Cancer Institute, Bethesda, MD, USA.

Forty-nine children with symptomatic HIV infection, ranging in age from 6 months to 13 years 10 months were evaluated with an age-appropriate neuropsychological test battery prior to entry on anti-retroviral treatment protocols at the Pediatric Branch, NCI. Children were tested when they were afebrile and free from acute infection. Twenty of these children had been perinatally infected (PERI; Mean age= 2.3 yrs) and were younger than the remaining 29 patients who were infected through contaminated blood or blood products (TRANS; Mean age= 8.1 yrs). Patients were also divided according to whether they had evidence of encephalopathy (ENCEP; eg loss of developmental milestones and/or positive neurologic or head CT findings) or not (INTACT).

Although a somewhat higher incidence of encephalopathy was found in the PERI as compared to the TRANS group (60% vs 31%; p > .10), analysis of the intelligence data indicated only a small, non significant difference in IQ (p> .10) between these groups. On the other hand, ENCEP patients had significantly lower IQ's (p< .001) than the INTACT patients. Infact most of the variance between the PERI and TRANS groups was accounted for by the different incidence rate in encephalopathy. The WISC-R IQ subtest profile in older patients revealed weaknesses often associated with Attention Deficit Disorder.

Analysis of the IQ equivalent scores for all patients on the Vineland Adaptive Behavior Scales, a semi-structured interview administered to the child's parent of primary caregiver once more indicated no significant differences (p> .20) between the PERI and TRANS patients. Again ENCEP patients had significantly lower IQ equivalent scores (p< .001) than INTACT patients.

Correlations between cognitive variables and hematologic, neurologic, and immunologic measures indicated the relation between observed behavior and physical status.

Complex methodological and sampling issues affect studies comparing PERI to TRANS patients. Due to differences in age, different standard IQ tests need to be administered to younger (~PERI) as compared to older children. Patients and family were screened for participation in treatment protocols at NCI, which could have led to selective sampling. Nevertheless, within our sample and with the available assessment methodology no strong indications were found of a more devastating effect of perinatal HIV infection on neuropsychological development.

T.B.P.176

NEUROLOGIC SYMPTOMS AS THE INITIAL PRESENTATION OF HIV INFECTION IN PEDIATRIC PATIENTS

Vincent, Judy*, Bash, M.*, Shanks, D.*, Daigh, D.*, Moriarty, R.*, Fischer, G.**, the Walter Reed Retrovirus Research Group
*Walter Reed Army Medical Center, Washington, D.C., United States of America
**Uniformed Services University of Health Sciences, Bethesda, Maryland, USA.

Objective. To describe the variability in the acute presentation of neurologic disease in children with previously unrecognized HIV infection.
Methods. Retrospective review of all military-dependent children who were diagnosed with HIV at WRAMC in the past 5 years.
Results. Twenty patients with HIV infection, P-1 or P-2, were seen at WRAMC since 1983. Initial clinical presentation with neurologic symptoms as the presenting complaint occurred in 3 patterns, as represented by the following 3 patients. One child with unrecognized perinatal HIV developed fever, stupor, and CSF pleocytosis at age 4 months, and was diagnosed as having CNS toxoplasmosis. Another child with perinatal HIV had regression in developmental milestones within the first 15 months of life, consistent with HIV encephalopathy. Later, he developed rapidly progressive neurologic deterioration and died of EBV-induced primary CNS lymphoma. A third child with transfusion-acquired HIV was considered well until age 4 years when he then began to develop ataxia, spasticity, loss of speech and fine and gross motor skills, and regression of cognitive functions.
Conclusion. CNS manifestations of HIV disease in children may vary from slowly progressive encephalopathy to rapidly deteriorating processes that include opportunistic infections and CNS tumors. Physicians who care for children should consider HIV in the differential diagnosis of any child who presents with neurologic symptoms of undetermined etiology.

T.B.P.178

PSYCHIC DEVELOPMENT OF CHILDREN BORN TO HIV INFECTED ITALIAN MOTHERS.

A. Condini, C. Cattelan, F. Viero, S. Casella, M. Zampiron, A.M. Laverda
Neuropsychiatric Service - Department of Paediatrics, University Of Padua
Padua, Italy

Objective: To investigate the influence of environmental conditions quality of mothers-child relationship and HIV infection status on psychic development of children born to HIV infected Italian mothers.
Methods: Psychic development (DA) of children born to HIV positive mothers is evaluated 3-monthly using: 1) development scales (Brunet-Lezine, Bailey) 2) psychodinamic observation of mother-child interaction. The development is considered abnormal when the difference between chronological and developmental age is more than 3 months. The mother-child relationship was classified as "adequate", "partially adequate" or "inadequate" according to a qualitative scale. Social data are evaluated with a special score: 0=deprived; 1=partially deprived-desorganized; 2=fair.
Results:are stratified according to the clinical status of the children (CDC criteria).
Results: 85 children were studied; 42 not infected, 24 infected, 19 indeterminate. There is no significative correlation between infection status and development χ^2 (p=0.98). In both infected and not infected patients there is a correlation between a low DA and inadequate mother -child relationship and a deprived/desorganized environment.
Conclusions: These findings suggest that the development of the children is more correlated to the socio-economic situation and to the quality of the relationship than to the clinical status

T.B.P.180

NEURODEVELOPMENTAL ASSESSMENT OF CHILDREN WITH SYMPTOMATIC HIV INFECTION.

Mittelman, Joan, Fikrig, S., Mendez, H., Skovera, F.
SUNY-HSC, Brooklyn, NY, U.S.A.

OBJECTIVE. To assess the neurodevelopmental outcome of 30 children with symptomatic HIV infection.
METHOD. Thirty children attending Pediatric AIDS Clinic at University Hospital have received neurodevelopmental evaluation as part of their clinical care. Infants under 30 months of age were evaluated on the Bayley Scales; those over 30 months on the Stanford-Binet Intelligence Scales, the Peabody Motor Scales, and the Purdue Peg Board. The Gordon Diagnostic System was used to test attention in children over 4.
RESULTS. The mean age of the children in this sample is 22.5 months with two-thirds of the sample under 30 months of age. Sixty-three percent have been diagnosed as having AIDS. Only 3 or 10% are functioning within normal limits. All three are less than 15 months of age. However, all of the rest of the infants under 15 months of age were severely cognitively impaired. Thus being young with this disease does not preclude developmental disability. Over half of the children were mentally retarded; 60% showed severe motor delays or a specific motor deficit. One-third of the children were functioning in the borderline range of intelligence. The two school-age children were in this range and had a learning disability.
CONCLUSION. While the neurodevelopmental sequelae of HIV infection are severe, these children are living and entering school and will require special education.

T.B.P.181

DEVELOPMENTAL ABNORMALITIES MAY OCCUR BEFORE OTHER CLINICAL MANIFESTATIONS OF PERINATALLY-ACQUIRED HIV INFECTION: A COHORT STUDY OF 119 ZAIRIAN CHILDREN BORN TO SEROPOSITIVE MOTHERS

Kabagabo, U.*; Bredon, K.**; Binyingo, M.***; Elonga, S.*; Ryder, Roberts/****. *Projet SIDA, Kinshasa, Zaire; **New Eng. Med. Ctr., Boston, MA; ***Ngaliema Hospital, Kinshasa;****CDC, Atlanta, GA.

Objectives. To prospectively evaluate cognitive, motor and neurologic development of infants with perinatally-acquired HIV infection (PI).
Methods. Three groups of children have been followed since birth. Group I consisted of 25 children with HIV(+) mothers and PI(HIV IgG at age 12/18 months or clinical AIDS). Group II had 93 non-infected children with HIV(+) mothers. Group III had 61 control children with HIV(-) mothers. Biannual Bayley Scale of Infant Development testing complemented monthly neurologic examinations.
Results. Mean Bayley Scores in children without AIDS signs/symptoms at the time of developmental testing

	Age 6 months		Age 12 months		Age 18 months	
	PDI	MDI	PDI	MDI	PDI	MDI
Group I	99	93	91	94	92	89
Group II	113	106	99	104	103	97
Group III	111	106	102	107	106	102
(p value)	(NS)	(.01)	(.01)	((.01)	((.01)	((.01)

(PDI=Psychometric Developmental Index; MDI=Mental Developmental Index)
(p values reflect Chi-square for trend for Gps I to III)
Fifteen percent of Gp I children and 4% of Gp II developed a neurologic abnormality during the first 18 months of follow-up (p=.06). Hypotonia was present in all 4 Gp I children with neurological disease. Other Gp I neurologic abnormalities included movement disorder, convulsive disorder and postural abnormality.
Conclusions. Developmental abnormalities may be the first sign of PI. These findings were noted as early as the age of 6 months and continued to be observed through the age of 18 months.

T.B.P.182

NEUROCOGNITIVE FUNCTIONING AMONG INFANTS EXPOSED PERINATALLY TO HIV

Swales, Thomas P.; Scott, G.B.; Cohen, D.S.; Carlson, R.G.; ; Falk, A.D.; Parks, W.P.
Departments of Pediatrics and Psychology, University of Miami, Miami, Florida, U.S.A.

Objective. The Fagan Test of Infant Intelligence (Fagan), a promising visual recognition memory test predictive of later mental retardation in high-risk populations, was selected for use in a prospective study exploring cognitive, developmental, and neurological aspects of pediatric HIV infection. This paper reports on our preliminary findings.
Methods. The Fagan was administered cross-sectionally to 19 infants at either six, nine or twelve months of age, along with Bayley, neurological exam, and laboratory studies. Subjects were the offspring of HIV+ Haitian mothers with no history of IV drug abuse.
Results. The sample yielded a mean Fagan novelty preference of 58.4% (SD=6.4). Two groups displayed attentional problems. Three infants were unable to maintain attention sufficiently to complete the task. Of those completing the task, four displayed abnormal visual recognition memory (novelty < 54%). The results of the Fagan testing are outlined below:

	HIV+	HIV-	Indeterminate	Total
Failed or incomplete Fagan	3	0	4	7
Passed Fagan	1	1	10	12

The HIV+ infants who failed the Fagan showed a consistent CNS involvement on the neurological exam and the Bayley. The one HIV+ infant who passed the Fagan also had normal neurological and Bayley findings. However, of the HIV indeterminate infants who failed the Fagan there was a lack of other abnormalities, with the exception of one infant who has a suspect Bayley.
Conclusions. Three of four infants with perinatally-acquired HIV infection exhibited decreased cognitive functioning as assessed with the Fagan, and consistent with deficits in neurological and developmental functioning. Further descriptive studies based upon infant habituation, memory and cognitive functioning are warranted.

T.B.P.183

NEURODEVELOPMENT IN CHILDREN WITH HIV INFECTION ACQUIRED FROM NEONATAL BLOOD TRANSFUSION

Cohen, Sarale*; Mundy, T.**; Karassik, B.**; Ward, J.***.
*UCLA School of Medicine, **Cedars-Sinai Medical Center, Los Angeles, CA.
***AIDS Program, Centers for Disease Control, Atlanta, GA.

Objective. The purpose of this report is to examine the neurodevelopmental course of children who acquired HIV infection as Neonatal transfusion recipients.
Methods. Neuropsychological batteries were administered to 16 HIV positive children and to a control group of 33 HIV negative children who also received neonatal blood transfusion. Serial assessments were conducted 8 months apart by a psychologist who was uninformed as to the HIV status.
Results. Scores on two batteries indicated that the HIV positive children were similar on most neuropsychological measures to the HIV negative group as long as 4-9 years after transfusion. The two groups did not differ in their overall intelligence. Deficits were observed in the HIV positive group in measures of school achievement, memory, and fine motor performance. There were no neurodevelopmental differences between the clinically asymptomatic, P1 (N=11) and the symptomatic, P2 (N=5) groups.
Conclusion. A high level of cognitive functioning may be maintained in children who acquired HIV infection as neonatal transfusion recipients. Neuropsychological deterioration observed was primarily in memory, attention, and fine motor behavior. Subtle differences in cognitive functioning may be an early manifestation of encephalopathy in HIV infected children.

T.B.P.184

DIVERGENCE OF ONSET OF NEUROLOGIC AND IMMUNOLOGIC IMPAIRMENT IN INFANTS BORN TO HIV SEROPOSITIVE MOTHERS

Calvelli, Theresa*; Belman, A.**; Busti, C.*; Golodner, M.* and Rubinstein, A.*
*Albert Einstein College of Medicine, Bronx, N.Y., U.S.A.; **SUNY at Stony Brook, Stony Brook, N.Y., U.S.A.

Objective. To compare the onset of neurologic impairment with the onset of immunologic dysfunction in a prospective study of perinatally infected infants.
Methods. Peripheral blood samples from 16 infants born to HIV-infected mothers were obtained during serial follow-up visits. HIV antibody was determined by ELISA and Western Blot. Lymphocyte subsets were determined by flow cytometric analysis of dual-color stained samples using whole-blood lysis methodology. Standard neurologic examinations were conducted at 3 month intervals.
Results. Three of 16 infants were both neurologically and immunologically normal through 2-7 months follow-up. Of 8 infants with neurologic impairment ranging from mild developmental delay to severe cognitive and motor defects, 5 showed early immune dysfunction reflected in decreasing T4/T8 ratios and low total T cells. Two of 3 infants with early neurologic dysfunction not accompanied by immune defects, developed immune abnormalities later. Five infants had normal neurologic exams, but showed immune dysfunction, including hypogammaglobulinemia, decreased total T cells, increased B cells, and decreasing T4/T8 ratios. Three infants remain serologically negative at 12-18 months, including the hypogammaglobulinemic child.
Conclusions. Neurologic dysfunction can precede, or occur in the absence of, immunologic impairment in infants born to HIV-infected mothers. Conversely, infants can show severe immune dysfunction with totally normal neurologic exams.

T.B.P.185

PATTERN OF NEUROLOGICAL ABNORMALITIES IN INFANTS AT RISK OF DEVELOPING AIDS.

Marcus, Joseph C+, Butler, CA+, Hittelman, JH+, Mendez, H+, Goedert, JJ*, Willoughby, A* et al. +SUNY-HSCB, Bklyn, NY & *NCI/NIH, Bethesda, MD, U.S.A.

Objective. To identify the onset and nature of neurological abnormalities in infants at risk of developing AIDS.
Method. The offspring of women at risk of developing AIDS- drug-abusers and Haitians- were examined neurologically at birth, then 3-monthly in the first year of life and 6-monthly afterwards, by 2 neurologists blinded to their serological status. Twenty-three with persistent abnormalities were found.
Results. Twenty-two infants showed varying degrees of speech delay, from 9 months to 2 years of age. Fourteen had abnormal hand function over 6 months to 1½-2 years of age. Eleven had persistent primitive responses, 6 being grasp reflexes. Of the 23, 6 are definitely infected, 7 have seroconverted, while 10 have HIV-negative mothers. The abnormal findings were noted in all 3 groups.

	Speech Delay	Abnormal Hand Use	Persistent Primitive Responses	Developmental Delay	Tone/Reflex Abnormalities
Infected	6	4	3	4	5
Seroconverted	6	5	3	3	3
HIV-negative	10	5	4	4	5

Conclusion. It has not been possible to establish a pattern of neurological abnormalities in infants at risk of developing AIDS, compared to their controls, nor is there any difference in the ages of onset. However, so far, only one child has shown any deterioration or loss of established functions.

T.B.P.186

NEUROLOGICAL MANIFESTATIONS IN PERINATALLY HIV INFECTED CHILDREN. A PROSPECTIVE STUDY

A. Laverda,P. Cogo, Del Mistro A.*,[illegible] M.,Ruga E.,Zacchello F. et al.
Department of Pediatrics, *Institute of Oncology, University of Padova,Italy.

Objective: To study the neurological manifestations in children born to HIV positive mothers.
Methods: All children born to HIV positive mothers in high risk groups are clinically and neurologically evaluated at birth and at 3 monthly intervals. The Brunet-Lezine scale is administered to all children 30 of age and Terman Merril test to the older patients every 3 months. The infected children only undergo CT scan, EEG, CSF study every year of earlier if clinically requested.
Results: Currently 15 children (median age 15.5 range 3-30 months) are infected, 42 are not infected (median age 24 range 9-39 months) 18 are indeterminate (median age 6.8 range 1-13). 4 of the infected children died of AIDS: 2 without any sign of neurological involvement, 1 had a progressive encephalopathy and 1 a primary brain limphoma. Isolated "soft" neurological signs (iperreactive reflexes, asymmetry of tone, unilateral upgoing toes)often transitory, were found in 5 out of the other 11 children and in 11 out of 42 not infected ones.(X^2, p)0.05). None of the infected patients had CT scan abnormalities nor developed microcefaly. We also compared the developmental score obtained at the last evaluation in infected and not infected children. The mean score in the infected was 82.22 and in the not infected 93.15 (p)0.05 Mann Whitney test).
Conclusion : Our preliminary results suggest that neurological and developmental abnormalities do not occur early in the course of vertical HIV infection.

T.B.P.187

EXPRESSION NEUROLOGIQUE GRAVE ET PRECOCE CHEZ UN NOUVEAU-NE INFECTE PAR LE VIRUS VIH.

Tricoire Joëlle*, Rolland, M*, Robert,A*, Delisle,MB,**, Puel, J***, Berrebi, A****

* Pédiatrie B, CHU Purpan, 31059 Toulouse Cédex, France; **Laboratoire d'Anatomo-pathologie, CHU Rangueil, 31057 Toulouse Cédex, France;***Laboratoire de Virologie, CHU Purpan, 31059 Toulouse Cédex, France;**** Clinique Obstétricale, CHU La Grave, 31300 Toulouse, France.

Objectif. Mise en évidence d'une infection par le virus VIH 1 chez un prématuré de 34 semaines né de mère positive (stade III CDC) qui présente une symptomatologie neurologique complexe, immédiate, d'évolution rapidement fatale.
Méthode. Les diverses investigations ont été centrées sur : - la neurologie (EEG, scanner cérébral, IRM ; EMG, examen anatomo-pathologique du cerveau, de la moelle et du muscle), - la virologie : sérologies VIH : Elisa (Pasteur), Western-Blot (D de Neumours), Ag p24 (Abbot) ; culture du virus et PCR.
Résultats. L'évolution rapidement fatale (J30) dans un tableau d'hypotonie globale peut faire évoquer soit une myopathie, soit une asphyxie périnatale et a permis de réaliser les examens suivants : - anatomo-pathologiques : au niveau du SNC (lésions ischémiques diffuses) ; - tests VIH : les examens sérologiques sont peu contributifs (sang, LCR) et seule la culture du virus sur les différents tissus et la mise en évidence par PCR ont apporté la preuve de l'infection.
Conclusion. La responsabilité respective du virus VIH et de l'anoxie-ischémie est discutée.

INCIDENCE OF OPPORTUNISTIC INFECTIONS IN 196 CHILDREN WITH SYMPTOMATIC AIDS IN KINSHASA

*Davachi, Farzin,*Mayemba, N.,*Kabongo, L.,*Ndoko, K.,*Ngoie, K. and **N'Galy, B.

*Deprrtment of Pediatrics, Mama Yemo Hospital and **Ministry of Health, Kinshasa, Zaire

Objective: To describe the incidence and variety of opportunistic infections in children with AIDS in Kinshasa, Zaire.
Methods: We examined 196 infants and children, one month to 12 years of age, hospitalized with symptomatic AIDS. HIV ELISA and Western Blot tests were positive for each patient.
Results: 127 (65%) children presented with opportunistic infections as follows: 82 (42%) with oral candidiasis, 33 (17%) with cutaneous mycosis, 17 (28%) out of 60 children tested, with tuberculosis, 12 (6%) with herpes simplex, 4 (2%) with mixed oral and cutaneous mycosis, 3 (1.5%) with herpes Zoster and 1 (.5%) with cryptococcal meningitis. It is interesting to note that children over 2 years of age had more opportunistic infections then infants and that Herpes Zoster and cryptococcal meningitis were absent in the infant group.
Conclusion: Oral candidiasis in older children is an important finding suggestive of AIDS. Herpes Zoster and Herpes Simplex, rare in our pediatric population, are being observed with increasing frequency in patients with AIDS. Extensive cutaneous mycosis has been invariably associated with AIDS. Tuberculosis is emerging as an important opportunistic infection in AIDS in Kinshasa. The incidence and variety of opportunistic infections in children in Zaire have different aspects from those found in children in the United States.

T.B.P.189

PERINATAL TRANSMISSION OF HIV INFECTION IN UGANDA: 0-34 MONTHS FOLLOW-UP

E.A. Mworozi, C.M. Ndugwa, P.K. Kataaha, S. Kiguli - Dept of Paediatrics Makerere University, Box 7072 KAMPALA, Uganda.

Objective: To determine the rate of HIV transmission from HIV seropositive expectant mothers to their infants and the morbidity and mortality characteristics of such children.

Methods: 87 babies born to HIV seropositive mothers and 64 babies born to seronegative mothers were followed clinically and serologically from birth - 34 months. The HIV status was determined by ELISA and W/Blot studies.

Results; All the study neonates and none of the controls were HIV seropositive at birth. The seroprevalence among the study infants declined to 35% by 15 months and 18.9% by 26 months. During the first year 11 children (14% in the study group died: failure to thrive (FTT) 5, acute gastroenteritis 2, measles 2, meningitis 1, pneumonia 1. Only 1 child (2%) in the control group died of pneumonia. During the 2nd and 3rd years, 2 children died in the study group: Aspiration pneumonia 1, FTT 1: One child in the control group died of poisoning. The remaining children in both groups who have been followed up have responded to immunization, although there is more morbidity among the study group.

Conclusions: 1. The rate of vertical transmission was about 20-30%. 2. Children born to HIV Seropositive mothers have higher infant morbidity and mortality rates compared to controls. 3. Immunization was found to be beneficial in both groups of children.

T.B.P.190

PEDIATRIC HIV INFECTION AT GAFFREE & GUINLE UNIVERSITY HOSPITAL. EPIDEMIOLOGIC, CLINICAL AND SURVIVAL CHARACTERISTICS.

Rubini, Norma de Paula Motta*; Signorini, D.J.H.P.*; Graça, M.H.P.*; Sion, F.S.*; Morais de Sá, C.A.*; Guimarães, M.D.C.**.

* Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil
** Federal University of Minas Gerais (U.F.M.G.) and FIOCRUZ (RJ)

Objectives: To investigate epidemiologic and clinical characteristics and to estimate survival time following initial symptoms among HIV infected children.
Methods: We evaluated 14 HIV infected children seen at Gaffrée & Guinle University Hospital in Rio de Janeiro, Brazil, from Jan.1984 to Dec. 1988. HIV laboratory diagnoses were performed by ELISA and Indirect Immunofluorescence. Clinical classification was based on CDC pediatric case definition. Survival parameters were estimated by product-limit function (Kaplan-Meyer).
Results: Among the 14 children evaluated 8 (57,1%) were perinatally acquired and 6 (42,9%) were blood transfusion related. Mean age at onset of symptoms was 33 months (2 - 108); 11 (78,6%) were males and 3(21,4%) females; 10(71,4%) were white and 4(28,6%)non-white. Maternal risk factors for the perinatally acquired infection were: 5(62,5%) IVDU; 2(25%) blood transfusion and 1(12,5%) bisexual partner. The clinical manifestations observed were: 8(57,1%) secondary infections diseases, 7(50,0%) non-specific findings, 1(7,1%) progressive neurologic disease and 1(7,1%) other diseases. Among 8 children (5 blood transfusion, 3 perinatal), with clearly defined onset of symptoms, 4(50%) had died by Dec 1988. Mean and Median were respectivelly 32,7 ± 8,1 months and 48 months. For the 5 transfusion related cases mean survival was 39,6 ± 10,6 months (median = 48 months) while for the 3 perinatal cases it was 9 ± 2,3 months (median = 11 months).
Conclusions: 1) There is a greater proportion of cases due to blood transfusion, as compared to other countries; 2) Maternal risk factors among the perinatal cases are similar to those reported in other studies; c) Mean survival time is smaller among the perinatal cases as compared to the blood transfusion.

T.B.P.191

KAPOSI'S SARCOMA IN 4 AFRICAN PEDIATRIC CASES

J.C.Bouquety*, M.K.Siopathis*, L.Lancaster**, F.R.Ravisse**, N.Lagarde***, A.J.Georges****

* Department of Pediatrics, Medicine and of Pathology, CNHU, BP 934, Bangui, Central African Republic; **Department of Pathology, Institut Pasteur, Paris, France; *** University (FACSS) of Medicine, Bangui, CAR; **** Institut Pasteur, BP 923 Bangui, Central African Republic.

Objective. To describe Kaposi's sarcoma (KS) in african pediatric cases.
Methods. 4 cases of KS occuring in children have been documented.
Case report N°1. A 8 month-old male african infant was hospitalized for chronic mild diarrhea and disseminated lymphadenopathy. He also had fever, cough, weight loss, herpes-like stomatitis and hepato-splenomegaly. A dozen of black-violet or dark brown skin nodules were present. The presence of antibodies to HIV-GP110 was detected by Western blot. Pathological examination of a lymph node a skin nodule confirmed the diagosis of KS. The lymph node showed lymphoid follicles with lage germinal center and mitotic activity and vascular hyperplasia. The pathological aspect are compatible with a KS at an early stage,with the special infiltrative aspect of AIDS-related KS. Histology of the skin showed vascular hyperplasia and proliferation of spindle cells, with large number of adjacent lymphocytes.
The evolution of the disease was fatal within 2 months. The peculiar aspects of the other 3 cases will be described.
Conclusion. This first pediatric case of KS was typical of the serie of four cases who were refered to the pediatric ward in one year.

T.B.P.192

STANDARDIZED ASSESSMENT OF PSYCHOPATHOLOGY IN AN HIV SAMPLE

Williams, J.B.W.; Rabkin, J.; Remien, Robert H.; Spitzer R., Gorman, J.; Ehrhardt, A.
HIV Center for Clinical and Behavioral Studies, NY State Psychiatric Institute and Columbia University, New York, N.Y., U.S.A.

Objective. To assess psychopathology using standardized clinical assessment measures in an HIV community sample.
Methods. The psychopathology of 198 gay and bisexual men, predominantly white, well-educated community volunteers was assessed with standardized measures. The Structured Clinical Interview for DSM-III-R was used to evaluate current and past psychiatric disorders. A structured interview guide was used to administer the Hamilton Depression (HDS) and Anxiety (HAS) Scales.
Results. Only 23% of the 119 HIV+ subjects had a current diagnosis; 16% was the corresponding figure for the 79 HIV- subjects. 8% of the HIV+ subjects and 6% of the HIV- subjects, respectively, had a current Mood Disorder. Average HDS scores were 4.3. for the HIV+ group and 3.2 for the HIV- group ($p=0.057$). Average HAS scores were 4.0 for the HIV+ group and 3.0 for the HIV- group ($p=0.076$). High levels of past but not current drug and alcohol use disorders were diagnosed.
Conclusion. These rates do not support early reports of high levels of depression in HIV+ gay men. However, these early studies used unstructured clinical interviews, interviews conducted by lay persons, and simple severity rating scales. More recent studies using structured assessment measures and clinical evaluations, have reported similar findings to ours. Thus, at least in our cohort, a diagnosis of HIV positivity does not necessarily entail severe psychological distress.

T.B.P.193

CLINICAL BEHAVIOUR OF 13 MEXICAN PEDIATRIC PATIENTS INFECTED BY THE HUMAN IMMUNODEFICIENCY VIRUS

Pérez Rguez Gustavo., Alvarez M.L., Gorbea R. M.C., Tórres G.F., Paredo L.V.-M., Hospital de Infectología, Centro Médico La "Raza", I.M.S.S. MEXICO

Objective.- To know the transmission mechanisms and the clinical evolution of the pediatric population infected by the HIV.

Methods.- We studied pediatric patients infected by the HIV from newborn to 13 years old according the Centers for Diseases Control critaria, From january 1985 to december 1988 .

Results.- We detected 13 patients; 10 male and 3 female. We found 7 hemophiliacs patients. Three patients had history for only one transfussion, and other one patient with multiple transfussion. One patient had history of the perinatal vertical transmission milk. The Disease was symptomatic in 12 patients and asymptomatic in other. In the present, 11 patients have development AIDS, and 6 was died. Clinical picture was the following: generalizate lymphadenopaty (13), fever (10), weigth loss (9), severe or recurrent infections (8), protacted diarrhea (7), hepatosplenomegaly (6), gastrointestinal bleeding (3), pneumonia (7), candidiasis (6), sepsis (5), cryptosporidium infection (5), gyardia infection (5), skin herpes infection (3), mumps infection (2), scabies infection (2) and middle ear infection (2).

Conclusión.- The principal mechanism of transmission was blood transfussion or its products; Almost all patients have development AIDS and the 46% had died.

T.B.P.194

PEDIATRIC AIDS: RISK FACTOR DISTRIBUTION AT HOSPITAL EMILIO RIBAS SÃO PAULO - BRAZIL

De Paula, Marinella Della Negra; Rodriguez, C.; Janini, M.; Suleiman, G.; Queiroz, W.; Soraggi, C.; et al.3rd Inpatients Unit- Hospital Emilio Ribas - São Paulo - Brazil

Objectives.Pediatric AIDS is being recognized in increasing number of children in our city. Since 1985, the 3rd Inpatients Unit of Hospital Emilio Ribas has been following children with positive epidemiological data for HIV infection. Up to November/88, 89 children younger than 10 years of age were enrolled. All of them fulfill the latest CDC criteria for pediatric AIDS. This report describes the risk factor distribution for the HIV infection in these patients. Methods. It was considered as risk factors:infants born into HIV soropositive mothers and children infected by blood transfusion and/or derivatives. All children and mothers were submitted to a double-Elisa, passive hemmaglutination (Salck-EIE-HIV and Quick HAP-HIV) and Western blot tests (biotech Du Pont Western blot kit). All the children are followed monthly for clinical and laboratorial examination and the ones classified as P-0 are submitted to new tests at the age of 8 and 15 months. Results. Vertical Transmission (71.9%) Maternal risk factor: I.V. Drugs 12(13.5%); high risk sexual activity 14(15.7%); I.V. Drugs and high risk sexual activity 29(32.6%); blood transfusion 1(1.1%); ignored 8(9.0%). Non Vertical Transmission (28.1%):blood transfusion recipient 14(15.79%); hemophiliacs 6(6.75%) and child's history unavailable 5(5.6%). Conclusion. The majority of our children got the HIV infection vertically, as it is observed in other countries. The association of drug-adiction with high risk sexual activity is the main factor for the maternal infection. The number of hemophiliacs in our cast is low because there is another center (Hemophiliacs Center) in our city that follows the majority of the infected hemophiliac children.

T.B.P.195

VALEUR PREDICTIVE DU STATUT CLINIQUE ET BIOLOGIQUE DE MERES HIV + SUR CELUI DE LEURS ENFANTS.

Matheron, Sophie.*; Di Maria, H.**; Courpotin, C.**; Brun-Vézinet, F.*; Dormont, D.***; Balloul, H.*.
* Hôpital Bichat, ** Hôpital Trousseau, *** Institut Pasteur, Paris, France.

Objectifs. Evaluer l'influence du statut maternel à l'accouchement sur une éventuelle contamination des enfants.
Méthodes. Le statut clinique, la virémie, le nombre de CD4 ont été mesurés parmi 25 femmes HIV + (20 HIV1, 5 HIV2) à l'accouchement. L'évolution clinique et sérologique et la virémie (V) ont été déterminés chez leurs 27 enfants.
Résultats. 1) La contamination de l'enfant ne dépend pas de la symptomatologie maternelle :

	Enfants infectés, V+				Pas d'infection prouvée*, V-	
Statut mère	SIDA	ARC	LAS	AST	LAS	Asymptomatique (AST)
SIDA : 2	-	-	-	-	-	2
ARC : 9	5	1	-	-	1	2
LAS **: 12	1	-	2	1	2	8
AST : 2	-	-	-	-	-	2

* Age moyen = 22 mois ; $3 < 15$ mois, sérologie +, AST; $14 > 15$ mois. sérologie -. ** syndrome lymphadénopathique. 2) Treize femmes ont eu une virémie : 7 sont V+, leurs 7 enfants sont V- ; 6 sont V- ; 5 de leurs enfants sont V- et 1 est V+. 3) 8 femmes avaient des CD4 < 400 : elles ont 8 enfants dont 5 sont V+; 14 avaient des CD4 > 400 : elles ont 14 enfants dont 2 sont V+, ($p < 0{,}05$).
Conclusions. 1) le statut clinique et virologique maternel à l'accouchement n'est pas prédictif du statut virologique et de l'évolution clinique des enfants.2)Le Nb de CD4 de la mère semble être un facteur prédictif significatif.

T.B.P.196

CRYPTOSPORIDIUM SP AND ISOSPORA BELLI INFECTIONS IN PEDIATRIC PATIENTS

De Paula, Marinella Della Negra; Queiroz, W.; Janini, M.; Soraggi, C.; Hughes, V.; Rodriguez C.; et al. Hospital Emilio Ribas, São Paulo, Brazil.

Objective.It is known that Isospora belli and Cryptosporidium sp are protozoa very frequently associated with acute self limited diarrheal illness in children and young adults. This evolution is not observed among immunocompromised individuals. This report shows the prevalence of Cryptosporidiosis and Isosporosis in pediatric patients with positive sorological anti-HIV tests. Methods. From January/87 to November/88, 25 children varying from 10 months to 10 years were analysed. All of them fulfill the pediatric AIDS criteria (CDC-1987): 4(16.7%) P-0; 1(4.2%) P-1 and 20(79.1%) P-2. All these patients have been followed-up monthly and had fecal samples collected for Cryptosporidium sp and Isospora belli screen. (One daily sample for 3 consecutive days). Results. Parasites were recovered from 13(52%) patients in the group analysed. Cryptosporidium sp isolate was recovered from 10 children (40%) and Isospora belli isolate from 2 patients (8%). Both parasites were recovered from one patient (4%). The recovery of Isospora belli was always associated with diarrheal illness at the moment of the diagnosis, whereas only one of the patients with Cryptosporidium sp presented diarrhea. All the other children with Cryptosporidial infection reported constipation.
Conclusion. Despite of being a tropical country we think that the prevalence rate of Cryptosporidium is higher than what is described in the scientific literature. In patients with Cryptosporidial infection, the main symptom related was constipation, unlikely what is observed among adults.

T.B.P.197

NATURAL HISTORY OF AIDS IN CHILDREN OF AFRICAN ORIGIN SEEN IN BELGIUM: EVIDENCE FOR TWO PATTERNS

Jonckheer, Tiil*, Levy, J.**, Alimenti, A.**, François, A.***, Winane, J.***
* Institute of Tropical Medicine, Antwerp, Belguie; ** Dept. of Pediatrics, Hôpital St. Pierre, Brussels; *** Dept. of Pediatrics, Cliniques Universitaires St. Luc, Brussels, Belgium.

Objective: To describe the diseases indicative of AIDS in children of African origin seen in Belgium.
Methods: The children of African origin with at least one disease indicative of AIDS according to the latest CDC-case definition were selected.
Results: Fourty-four children met the inclusion criteria (male/female ratio = 1). Three (7 %) had a history of blood transfusion in Africa, the others were presumed to be born to an HIV infected mother. Following diseases indicative of AIDS were diagnosed: bacterial infections (n = 24), LIP/PLH complex (23), PCP (10), HIV encephalopathy (9), Candida albicans (5), herpes simplex (1), disseminated BCG (1), HIV wasting syndrome (1), HIV related cancers (1). Thirteen children (25 %) are known to have died, 9/13 before the age of 12 months, all the others (4/13) after the age of 78 months. Thirty-one (77 %) were still alive when last seen (mean age 36 months, median 29 months, range 5-104 months). Twenty children (45 %) had only LIP/PLH complex and/or bacterial infections when last seen (mean age 48 months, median 44,5 months, range 8-103 months, mode 40-49 months), whereas 24 children (55 %) had "true" opportunistic infections and/or HIV encephalopathy and/or HIV related cancers when last seen (mean age 29 months, median 11.5 months, range 4-126 months, mode 0-9 months).
Conclusions: Our data suggest that the natural history of HIV infection in African children is characterized by at least two patterns: one group of infants and younger children with rapid onset, a more severe expression of the disease and poor prognosis, and a second group of older children with later onset, a more chronic expression (only LIP/PLH complex and/or bacterial infections) but with potential poor prognosis after several years of evolution.

T.B.P.198 PERINATAL TRANSMISSION OF HIV-1: IS A DECREASED CD_4 CELL COUNT PREDICTIVE?

Daniel, Bonnie J, Hauer LB, Wofsy CB, Crombleholme W, Weintrub P, Wara D, Sweet RL, et al; University of California, San Francisco, San Francisco General Hospital, USA.

Objective. To investigate possible immunologic, virologic and/or clinical factors which might correlate with perinatal transmission of HIV-1. Methods. Pregnant HIV+ women were followed prenatally and postpartum with testing for immune function, HIV-1 in peripheral blood, and P_{24} Antigen (Ag). Infants were considered infected (+) if they had a + blood culture, and/or + Polymerase Chain Reaction (PCR), ± signs and symptoms. Equivocal infants (E) had equivocal culture results,and/or an equivocal PCR. Uninfected infants (-) had - cultures, - PCR, no signs and symptoms, and no HIV-1 Ab at 15 months. Results. Preliminary data are available on 16 mothers and 15 infants (1 mother had twins, 2 are still pregnant.) Overall, 3/15 infants (20%) were +, 1/15 (7%) was E (further results pending) and one is - but shows cortical atrophy suggestive of HIV-1. No mother had a + P_{24} Ag; 3/16 had + blood cultures resulting in one + infant, one - infant, and one due 6/89. Clinical signs and symptoms in mothers did not appear to correlate with perinatal transmission, but decreased maternal CD_4 cells did:

Pair #	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
CD_4	209	221	235	272	284	298	304	363	417	466	531	587	674	862	947	1185
Infant	- *	+	+	- **	+	-	due 6/89	-	E	-	-/- ***	-	-	due 2/89	-	-

* sibling died of AIDS ** cortical atrophy in infant *** twins

Conclusions. Preliminary results from this small sample show a decreased CD4 cell count as the only correlate to perinatal HIV-1 transmission. If substantiated by continued study of more mother-infant pairs, this may be of value to HIV+ women deciding whether to initiate or continue a pregnancy.

T.B.P.199 PULMONARY INFECTIOUS COMPLICATIONS IN PEDIATRIC AIDS PATIENTS.

De Paula, Marinella Della Negra; Janini, M.; Queiroz, W.; Hughes, V.; Rodriguez, C.; Lorenço, R.; et al. Hospital Emilio Ribas, São Paulo, Brazil

Objective. Infectious pulmonary processes are very common among HIV infected children. This report shows the etiologic agents more frequently associated with pulmonary disease among our children. Methods. From January/86 up to November/88, 42 children aged from 2 months to 10 years were followed monthly. All of them fulfill the latest CDC pediatric criteria. When there was any suspect of pulmonary disease they were submitted to radiologic and bacteriologic tests (culture of: blood, gastric contents, sputum, pleural effusion, etc.) In many patients the etiology was not confirmed, but supposed by the clinical examination and terapeutic proof. Results. Twenty-seven (64.3%) of the children developed a pulmonary disease. Four children (9.5%) had Pneumocistis carinii pneumonia. In all of them the diagnosis was based on clinical and radiological aspects and terapeutic proof. Twenty-five (59.5%) of the children had, at least, one bacterial pneumonia and the agents more frequently found was S. aureus and S. pneumoniae. Fourteen (33.3%) of the patients had pulmonary tuberculosis. Ten of these patients had gastric contents collected and Mycobacterium tuberculosis was isolated in 7 cases. One of them had acid-fast bacili isolated from liver biopsy.All the 14 had improvement with standard terapeutic. Conclusion. The incidence of pneumocistosis and bacterial pneumonias in this report is compatible with the medical literature. The incidence of tuberculosis seems to be greater than what is described. We believe that this high indicence is due to the high prevalence of tuberculosis in our country.

T.B.P.200 Perinatal and Heterosexual Transmission Through HIV-Positive Women

Rehmet S., Staszewski S., Wegerich B.°, Kreuz W.°, Stille W., Zentrum der Inneren Medizin, ° Zentrum der Kinderheilkunde, Universitätsklinik Frankfurt

Since 1984, we have examined HIV-infected women and their partners in order to gain information on infectiosity, perinatal & heterosexual transmission rates, and possible relations between these factors. 44 Women examined in this period had born a total of 47 children since their HIV infection. 10 children are positive for HIV, 31 are negative for antibodies and direct virus identification; in 6 cases, HIV status is still questionable. A comparison between the group of women having infected their children and those not having transmitted the virus, shows no difference regarding immunological parameters, stage of HIV infection, tests for lues, CMV, and HBV. Of the women having infected their children, 60% were HIV stage 2a (Frankfurt classification); 40% were 2b with a median T4 cell count of 430 (27-984), the median ratio being 0.56 (0.03-0.92), duration of infection being 1-6 years. Out of 44 women, 33 women's partners are known and were tested for HIV: 16 are positive, 18 are negative for HIV. In no case had the man been infected by his HIV-positive female partner; also women having infected their children did not infect their partners.

Conclusion: Regarding immunological status, HIV stage at first examination, and tests for CMV, lues and HBV, there was no difference between mothers of infected, and mothers of non-infected children. The women having infected their children were immunologically good. This allows the conclusion that infection of children is also possible at an early stage of the mother's infection.

T.B.P.201 Immunological,serological and clinical evaluation of HIV pos. pregnant women in relation to vertical transmission of HIV.

M L Muggiasca°,M Conti,°N Zanchetta*,L Salvaggio*,R Novati°°,E Massironi**
°VII dep.Obste.Gynecol.;*V dep.Hygiene;°°dep. Infect.Diseases;**dep.Paediat., University of Milan. Milan, Italy

Objective To evaluated the prevalence of vertical transmission of HIV in relation to immunity,HIV related diseases and viral replication in their mothers.

Methods 23 HIV pos.pregnant women(6 IVDA;13 ex-IVDA;3 partners of HIV)have been clinically evaluated and tested for HIV circulating antigen(p24 Ag,Elisa, Abott),antibody(p24 Ab,W.B.,Du Pont)and lymphocyte subset(monoclonal antibodies,Ortho).Their children have been followed bimounthly with clinical, serological and immunological evaluation.CDC classification for paediatrics and adult HIV infection was followed.

Results 5 women were affected by ARC(CD4+mean 390.4S.D.±152.4).1 was p24Ag positive.Their infants were:2 AIDS,1 not infected(anti HIV neg.after 15th m), 2 P0. 7 women were affected by LAS(CD4+ mean 537.28 S.D.±253.1).Their infants were:1 AIDS,1 P1,4 P0,1 not infected(anti HIV neg.after 15th m.). 11 women were asymptomatic (CD4+ mean 607.2 S.D.±260.1).1 was p24Ag positive.Their infants were:1 AIDS,8 P0 and 2 not infected(anti HIV neg.after 15th m.).

Discussion These preliminary results show the importance to followed clinically,serologically and immunologically the HIV pos.women and their children for almost two years from delivery.

T.B.P.202 CLINICAL AND SEROLOGIC PROSPECTIVE STUDY IN INFANTS BORN FROM HIV SEROPOSITIVE MOTHERS.

Fortuny Claudia, Sanchez C, Barrera JM, Ercilla MG, Navio D, Jimenez R, Gelabert A. Dept. Pediatry and Blood Transmitted Diseases Unit. Hospital Clinic. Villarroel 170. Barcelona. Spain.

Objective: To evaluate the serological and clinical evolution of newborns (NB) from seropositive mothers.

Methods: 70 NB were clinically controlled monthly and serologically (HIV-Ab, HIV-Ag) each two months.

Results: At birth all NB showed IgG Ab against HIV-1 with a mirror pattern in Western Blot (WB) when compared with the mother's serum.
83% of NB with a follow up >10 months turned to a seronegative state in 10 ± 2 months (range 6-14) without clinical symptoms. These seronegative sera were controlled by ELISA and WB, antigaenemia was never detected.
Five infants developed AIDS (P2) and three were in P1 stage in a follow up of>15 months. AIDS diagnosis in four cases was assessed before age of 12 mths
Detection of antigaenemia indicates a poor clinical prognosis.
Mother's serum of patient that developed AIDS before age of 3 mths lacked reactivity against p17.

Conclusion: The rate of maternal-infant transmission was observed in 19% of infants with a follow up > 15 months. Serological monitorization of NB by WB and levels of antigaenemia is very useful to predict diagnosis and clinical evolution.

T.B.P.203 OPHTHALMIC MANIFESTATIONS OF HIV INFECTION IN AN AFRICAN PEDIATRIC POPULATION.

Kestelyn, Philippe ; Lepage, P. ; Stevens, A.M.* and Van de Perre, P.***.
*Department of Ophthalmology and **Department of Pediatrics, Centre Hospitalier de Kigali, ***National AIDS program, Kigali, Rwanda, Africa.

HIV infection in adults is associated with a wide variety of ophthalmic manifestations. The purpose of this study was to investigate the spectrum of ophthalmic involvement in a pediatric HIV seropositive population.

Methods. All seropositive children attending the department of pediatrics of the Centre Hospitalier de Kigali were referred to the ophthalmology department of the same institution for a routine ophthalmic examination. This included inspection of the outer eye, motility testing, and fundoscopy after dilatation. Children with normal findings had follow up examinations every six months, while those with a pathologic eye exam were seen more frequently. Hundred and ten HIV infected children were followed over a three year period.

Results. Sixty three (57%) children exhibited some form of ophthalmic involvement during the study period. Involvement of the peripheral retinal vessels either in an active form (retinal perivasculitis) or in a cicatricial phase (perivascular sheathing) was the predominant finding. Cotton wool spots, the most common ocular manifestation of HIV infection in adults, were almost absent in these children. Decreased lacrimation indicative of lacrimal gland pathology was another common finding (see table).

Ocular findings	No. of children (%)
Perivasculitis and/or sheathing	52 (44%)
Decreased lacrimation	22 (20%)
Microvascular abnormalities	9 (8%)
Chorioretinitis	6 (5,4%)
Retinal haemorrhages	2 (0,8%)
Cotton wool spots	1 (0,9%)

Conclusion. The picture of ophthalmic manifestations of HIV infection in children is quite different from that in adults.
Although a biological explanation for the observed differences seems likely (immaturity of the immunological system in children), the possibility that our study group is not representative of all HIV seropositive children should be born in mind (survivor bias). We are currently participating in a prospective study on the vertical transmission of HIV in order to document the ophthalmic involvement associated with this infection in a cohort of children to be followed from birth till age 3.

T.B.P.204

ANTHROPOMETRIC MEASURES IN A COHORT OF CHILDREN BORN TO HIV+ WOMEN IN KINSHASA, ZAIRE.

Hassig, Susan E.*/**; Manzila, T.*; Nsa, W.*; Kashamuka, M*; Ryder R.*/***. *Projet SIDA, Kinshasa Zaire; **Tulane University, New Orleans, USA; ***CDC, AIDS Program, Atlanta, GA, U.S.A.

Objectives. To determine the prevalence and correlates of wasting and stunting in a cohort of children born to HIV+ women.
Methods. Monthly weights, heights and illness experience (diarrhea, pneumonia, fever) were collected on 366 children born to HIV+ women and 513 children born to HIV- women. Weight-for-height (wasting) and height-for-age (stunting) indices were computed using National Center for Health Statistics standards. Data on maternal factors, including socioeconomic status(SES) were also collected.
Results.

	HIV+ mother		HIV- mother	p value
	Infected	Not infected		
7 Months	N=97	N=259	N=494	
% Stunted	15.5	6.8	5.5	0.002
% Wasted	4.1	1.9	1.0	0.08
12 Months	N=81	N=259	N=501	
% Stunted	19.3	7.3	6.0	0.0001
% Wasted	16.3	11.2	4.8	0.0001

Other independent correlates of wasting and stunting at 12 months include low SES (p=0.0000) and multiple illnesses (p=0.0000) and low birthweight (p=0.0000). Infected children stunted at 12 months had higher mortality at 18 months than non-stunted (38% vs. 6%, p=0.002).
Conclusion. Stunting in conjunction with HIV infection may place these children at high risk of premature mortality.

T.B.P.205

HIGH HIV-ASSOCIATED INFANT MORTALITY CORRELATES WITH POOR POST-PARTUM MATERNAL HEALTH: 18 MONTHS FOLLOW-UP OF 477 CHILDREN(CH) BORN TO HIV(+) MOTHERS(MO) IN ZAIRE

Badi, Nsenga*; Ryder, R.*/**; Nsuami, M.*; Matela, B.*; Nsa, W.*; *Projet SIDA, Kinshasa, Zaire; **CDC, Atlanta, GA.,U.S.A.

Objectives. To determine mortality/1000 live births and associated postpartum maternal risk factors in CH with perinatally-acquired HIV infection(PI).
Methods. Infant cause of death and maternal factors predictive of PI and infant mortality were prospectively determined during the 18 month postpartum period in 3 groups of CH and their MO. Group I had 120 CH with PI (HIV IgG at age 12/18 months or clinical AIDS) and 70 HIV(+) MO. Group II had 357 CH without PI and 70 HIV(+) MO. Group III had 390 control CH without PI and 70 HIV(-) MO. CH were investigated in a prospective cohort study and MO in a nested case-control study.
Results. Child mortality rates and prevalence of maternal factors by group

CHILD MORTALITY (Prospective cohort study)	GpI	GpII (P)	GpIII (P)
Infant mortality rate(through age 12 mos.)	225	188 (<.01)	39 (<.01)
Total mortality rate(through age 18 mos.)	358	204 (<.01)	42 (<.01)
Cause-specific mortality(through age 18 mos.)			
Diarrhea(DIA)	183	48 (<.01)	8 (<.01)
Pneumonia(PNEU)	75	25 (<.01)	2 (<.01)
Meningitis	33	20 (<.05)	5 (<.01)
Measles	25	8 (<.01)	5 (<.01)
MATERNAL FACTORS (Nested case-control study)			
Clinical AIDS(%)	40%	19 (<.01)	9 (<.01)
Tuberculosis(%)	13%	3 (<.05)	1 (<.01)
Hospitalized(%)	26%	10 (<.01)	1 (<.01)
Infant dying(%)	31%	7 (<.01)	3 (<.01)
Mother dying(%)	9%	12 (NS)	0 (<.01)

(p values are for comparison of Gp I with Gp II and Gp I with Gp III)
Conclusions. CH born to symptomatic HIV(+) MO had high mortality rates, particularly from DIA and PNEU, during the first 18 months of life. MO of CH who died appeared more infectious in the perinatal period and/or less able to optimally care for their CH in the postpartum period.

Pediatrics: Immunology

T.B.P.206

PERINATAL IMMUNE FUNCTION IN OFFSPRING OF HIV SERONEGATIVE WOMEN AT RISK FOR AIDS.

Rich, Kenneth*; Landay,A.**; and Chasnoff, I.***. *University of Illinois, **Rush Medical College, **Northwestern University. Chicago, IL, U.S.A.

Objective. To examine possible association of maternal immune function on the immunologic function of infants ≤ 6 weeks old.
Methods. Substance abusing women at risk for HIV infection and their infants ≤ 6 wks. old were tested for their immune function. Patients were excluded if HIV infected. Lymphocyte phenotyping was performed on Ficoll-Hypaque prepared mononuclear cells (MNC) and examined by 2-color flow cytometry. Standard PHA stimulated blastogenesis was assayed using cultures of 10^5 MNC per well cultured for 72 hrs. in the presence of 1 or 0.25 ugm PHA.
Results. Significant, possibly maturation dependent, differences in the % of CD4 (p=.043) and CD8 (p=.002) cells was observed between infants and their mothers. CD4/CD8 ratio was 1.6±0.6 in mothers and 3.6±1.9 in infants. A significant correlation existed between the Leu 19 bearing lymphocytes (an NK subpopulation) of the mother and infant (p=0.014, corr. coef. 0.7438, n=10) with a mean % Leu 19 of 11.5±5.7 for mothers and 9.8±5.3 for infants.

PHA response was significantly different between mothers and their infants at 1 ugm (p=.005) and 0.25 ugm (p=.009). Despite the differences, a significant correlation existed between infant and mothers' response at 0.25 ug (p=.004, corr. coef. 0.7, n=17).
Conclusion. Correlation between the infant and maternal immune function suggests an influence of the prenatal maternal environment on the infant immune function, irrespective of HIV infection. Further examination of the interaction between mother and infant immune function is needed.

T.B.P.207

ADCC IN HIV-1 INFECTED CHILDREN

Walter, Emmanuel; McKinney, R.; Wilfert, C.; Tyler, D.; Bolognesi, D.; and Weinhold, K.. Duke University Medical Center, Durham, NC, USA.

Objective. To determine the prevalence of antibodies directing gp120 specific antibody-dependent cellular cytotoxicity (ADCC) within a cohort of HIV-1 infected children.
Methods. Sera from 35 HIV-1 infected and 10 seronegative children (ages 1 mos-13 yrs) were evaluated for ADCC directing activities in a series of 6-hr ^{51}Cr release assay using normal donor lymphocyte effectors and gp120 coated CEM.NKR (natural killing resistant) targets.
Results. ADCC activity was detected in 71.4% of the pediatric sera tested. The mean percent specific lysis was 17.2% - approximately half the level seen among infected adults. Among children with ADCC activity maximal lysis occurred between a serum dilution of 1:200-1:2000 (mean titer 1:950). ADCC activities varied little among 9 of 10 children followed over one year. One infant with vertically acquired HIV did not develop ADCC activity until 12-17 months of age. Minor trends were noted in relation to ADCC activity correlated with age and mode of acquisition. ADCC did not differ significantly when divided by CDC pediatric disease classification.
Conclusion. ADCC directing HIV-1 specific antibodies are present in nearly 3 of 4 infected children. Levels of ADCC, though highly variable, are considerably lower than adult levels suggesting a possible rationale for passive antibody therapy in infected pediatric patients.

LONGTERM-FOLLOW UP OF IMMUNOLOGIC PARAMETERS IN HIV-EXPOSED INFANTS

Wintergerst, U., C.Rosendahl, R. Lutz, E.Fahrenheim, B.H. Belohradsky

Immundefekt-Ambulanz der Universitats-Kinderkliniken, Lindwurmstr.4, 8000 Munchen 2, West-Germany

Introduction: Infants with ARC or AIDS following vertically acquired HIV-infection develop severe B- and T-cell defects.The longterm follow-up of immunologic parameters was studied in vertically HIV-infected versus HIV-exposed infants, who became HIV-Ab negative and were otherwise healthy.
Methods: Since 1985 35 children could be evaluated clinically, serologically, virologically and immunologically in regular intervals. The following immunologic parameters were explored: Total number of CD4, CD8, CD20 positive cells, stimulation with Phytohaemagglutinin (PHA), OKT3, Pokeweed Mitogen (PWM), Staphylococcus aureus protein (SAC) and different antigens (Mumps, Tuberculin, Vaccinia, Streptolysin O, Tetanustoxoid). The infected group included 15 infants; 12 children lost HIV-Ab and are clinically healthy and in 8 children the infection is still uncertain.
Results: The total number of CD4 positive cells in HIV infected children younger than 20 month without AIDS is comparable to the CD4-cell-count in HIV-Ab negative children. This number decreases in older infected children and in children with AIDS, despite IVIG-therapy. Pathologic stimulation data of PHA and OKT3 correlates with the course of CD4 cell numbers and CD4/CD8 ratio. The stimulation with PWM and particularly SAC seemed independent of CD4 cell count. PWM stimulation in infected children is already low when CD4-cell-counts are still normal. However, when CD4-cell counts are low, stimulation data of all mitogen are pathologic. The antigenic stimulation could not be demonstrated either in HIV-infected nor in HIV-Ab negative infants under the age of 20 months.
Conclusion: Both asymptomatic HIV-infected infants and HIV-exposed infants, who became HIV-Ab negativ have normal immunological functions in the first 20 month of their life. Then in HIV-infected infants a progressiv immunological deterioration develop despite therapy with i.v. immunoglobuline.
With cautious interpretation of our data PWM-stimulation seems the earliest immunologic marker for HIV-infection.
For routine immunological surveillance of asymptomatic HIV-exposed children quarterly determination of the CD4/CD8-Ratio is sufficient.
(With support of the BMJFFG, Titel 1502/[illegible] and the BMAS Titel 71)

T.B.P.209

HIV-SPECIFIC IMMUNE RESPONSES IN CONGENITAL HIV INFECTION.

Katherine Luzuriaga*; Koup, R.*; Panicali, D.** and Sullivan, J*. *University of Massachusetts Medical School, Worcester, Massachusetts, USA, **Applied bioTechnology, Inc., Cambridge, Massachusetts, USA.

Objective: To investigate HIV-specific immune responses in infants and children with congenital HIV infection.
Methods: Diagnosis of HIV infection was made in 7 children by viral isolation. HIV-specific antibody-dependent cell-mediated cytotoxicity (ADCC) was studied in all of the children using an EBV-transformed lymphoblastoid cell line (BLCL) infected with recombinant vaccinia (vac) virus vectors expressing HIV envelope glycoproteins (env) as target cells. HIV specific cytotoxic T-cell (CTL) responses were studied in five of the seven children using B LCL's infected with recombinant vac expressing HIV env or gag proteins as target cells and freshly-isolated autologous lymphocytes as effector cells.
Results: ADCC antibodies directed against env were detected in five of the seven children (titers 1:100 to 1:100,000). These antibodies were detected as early as one month of age and as late as sixty months of age. Progression from asymptomatic to symptomatic infection has occurred despite sustained ADCC titers in these children.

All five children tested demonstrated CTL responses against both the gag and env proteins (vac alone 4.9%, vac/gag 11.6% and vac/env 21.4%).
Conclusions: Active HIV-specific ADCC and CTL responses can be detected in congenitally-infected children may be important in the immunopathogenesis of HIV infection.

T.B.P.210

HIV INFECTION IN INFANTS: NATURAL HISTORY AND OUTCOME

Johnson, John P., Nair, P., Advani, M., O'Neil, K., Seiden, S, Hines, S., University of Maryland School of Medicine, Baltimore, Maryland. U.S.A.

Objective. To deterine the natural history and outcome of HIV infection in infants.

Methods. 35 children born to seropositive women were followed from birth to 18 months. Physical exam and laboratory data were collected at 2,4,6,9 and 12 months of age. Nine of these children were confirmed infected by increasing IgG against HIV; 6 children were documented by the presence of IgM against two or more antigen classes of HIV. The remaining 20 children served as non-infected controls.

Results. The IgG seroconverters developed unusual degrees of adenopathy by 2 1/2 months, skin disease at 3 months, splenomegaly by 4 months, hepatomegaly by 5 1/2 months, and neurologic and laboratory abnormalities by 6 1/2 months of age. These findings were significantly different from the non-infected children. Although the IgM seroconverters showed increased adenopathy, neurologic abnormalities and skin disease, none of these abnormalities were significantly more frequent than in controls. All of the IgG positive children fell within P2 classification by 12 months of age, 4 developed AIDS. Only 1 of the IgM seropositive children fell in the P2 category.

Conclusion. Children who develope IgG against HIV within the first year of life appear to have a worse prognosis than those who are solely IgM seropositive. This suggests that isolated IgM seropositivity is a good prognostic indicator in HIV infected children.

T.B.P.212

SERUM INTERLEUKIN 2 RECEPTOR (sIL-2R) LEVELS IN NEONATES BORN OF HIV-INFECTED MOTHERS: PRELIMINARY RESULTS

Ridolfo,A.L.*; Galli,Massimo*; d'Arminio Monforte,A.*; Cocchi, F.*; Novati,R.*; Marchisio,P.**; Massironi,P.** and Balotta,C.*.
*Infectious Diseases Clinic;**Pediatric Dept.V,University of Milan, Italy.

Objective. To state whether sIL-2R levels present any difference between infected and non-infected neonates.

Methods. sIL-2R serum samples were quantified using an ELISA method (T Cell Science) in the 7th and 14th month in 13 neonates born of anti-HIV positive mothers. IgG anti-HIV (ELISA,Abbott; Western Blot, WB-DuPont), IgM anti-HIV (WB-DuPont) and p24 Ag (ELISA,DuPont) were tested. Children who became seronegative were considered as non infected children (all asymptomatic, persistently IgM anti-HIV and p24 Ag negative) (n=5). Symptomatic or immunodepressed children (n=5), asymptomatic and immunocompetent IgM anti-HIV and/or p24 Ag positive at any age (n=3) were considered infected.

Results. sIL-2R levels were quite comparable in the 7th month between the two groups (2392±901 versus 2781±897). In the 14th month sIL-2R levels were decreased in all 5 non infected children and increased in all 8 infected children (mean: 1602±433 versus 3485±1370).

Conclusions. These preliminary data seem to indicate a possible correlation between sIL-2R variable levels and the serological and clinical status of children studied.

T.B.P.214

IMMUNOLOGICAL ABNORMALITIES IN HIV INFECTION BY VERTICAL TRANSMISSION

Español,Teresa,Curell,N.;Figuera,T.;Quer,J.Garcia,X.and Caragol,I.Immunology and Pediatric Infectious Diseases Units.R.S.Valle Hebrón. Barcelona.Spain.

The first risc for AIDS in Spain is drudaddiction and the number of cases by vertical transmission is 2,6 % of the total.

Immunological abnormalities are very severe in children infected during pregnancy or perinatally,and early diagnosis is important to stablish therapeutic protocols to avoid progression of the disease.

We have studied the synthesis of lymphokines (IL-1,IL-2 and γ-IFN) and the production of Ig "in vitro"in a group of 15 HIV + children (4 m.to 4 y.old in order to define the mechanism involved in the immunodeficiency,mainly of the antibody response,that conditions the high frecuency of bacterial infections demoentrated in these patients.

Lymphocyte subsets,Ig and Ig G subclasses and antibody levels,and lymphocyte response to mitogens were studied in all patients with standard method Lymphokines were measured in PBL culture supernatants after stimulation with LPS/ 24 h.(IL-1) and PHA/ 48 h.(IL-2 and γ-IFN) with ELISA and RIA methods respectively.Production of Ig "in vitr" was quantitated on supernatants of PBL cultures stimulated with PWM/12 days.

Synthesis of Il-1 is very high,included in the unstimulated cultures, but IL-2 and γ-IFN decreases more rapidely during evolution ofthe disease. Although hypergammaglobulinemia is a common feature of these patients we have detected 2 cases of Hypogammaglobulinemia and poor antibody response and low Ig G_2 levels in half of the cases.

New therapeutic protocols with lymphokines must be considered.

T.B.P.211

PERINATAL TRANSMISSION OF HIV - INDICATORS OF INFECTION

Jacqueline Mok*;RA Hague*;FD Hargreaves*;J Whitelaw ;PL Yap^
*City Hospital,Edinburgh, HIV Immunology Lab, Western General Hospital, Edinburgh,^South East Scotland BTS, Edinburgh,UNITED KINGDOM

Objective: To define the natural history of vertically acquired HIV infection and to elicit methods for early diagnosis.

Methods: Forty nine index infants born to HIV seropositive mothers have been followed up for a median duration of 27 months, together with 24 control infants of HIV seronegative mothers.

Results: Clinical signs and symptoms were non-specific, and seen in both index and control children. Significantly more index children showed persistent lymphadenopathy (23% vs 0% $p<0.05$) and recurrent respiratory infections (30% vs 9% $p<0.05$). Laboratory abnormalities were non specific and also seen in both index and control children. Within index children, four had proven HIV infection (HIV Ab, Ag and culture positive) while 37 over the age of 18 months were presumed uninfected on clinical and laboratory criteria. In the infected children, hypergammaglobulinaemia was detected as early as six months, often before the onset of clinical signs or symptoms. With progression of disease, other useful laboratory markers were T4 lymphopaenia and thrombocytopenia.

Conclusion: In the absence of specific clinical criteria for diagnosing HIV infection, a useful early laboratory marker is hypergammaglobulinaemia; while T4 lymphopaenia and thrombocytopenia occur with disease progression.

T.B.P.213

SERUM NEUTROPHIL ANTIBODIES IN CHILDREN WITH HIV INFECTION

Church, Joseph A.; Beyer, L. and Coates, T. Childrens Hospital of Los Angeles, and U.S.C. School of Medicine, Los Angeles, California U.S.A.

Objective: To determine the prevalence of serum neutrophil antibodies (NA) in children with HIV infection and the relationship of NA to neutropenia in these patients. Methods: Serum was obtained from 18 HIV-infected children, 9M, 9F, 1 to 7 years of age (mean 3.5 ± 1.5). 3 were asymptomatic (P-1), 6 had ARC (P-2A,F) and 9 had AIDS (P-2B,C,D). Neutrophil (N) counts were calculated from routine blood counts. IgG and IgM NA were detected with an indirect immunofluorescent assay. N from normal donors were incubated with patient serum, labelled with FITC-goat anti-human-IgG or -IgM, and analyzed with a FACScan® automated flow cytometer. A test serum was considered positive if a definite fluorescent peak shift was observed on the histograms generated with N from 3 donors. Normal donor sera are negative for NA with this assay. Results:

	P-1 (3)	ARC (6)	AIDS (9)
N count	2090 ± 632	3142 ± 1412	4529 ± 4039
+ IgG NA	3	5	6
+ IgM NA	3	6	7

Two patients had neutropenia, 1 had negative IgG NA and 1 had negative IgM NA. There was no correlation between reduced N counts and positive or negative NA assays. Conclusions: IgG and IgM NA were detected in most HIV-infected children. The presence of NA was not related to clinical status or N counts.

T.B.P.215

IMMUNOGLOBULIN E (IgE) IN CHILDREN WITH ADQUIRED IMMUNODECIENCY SYNDROME (AIDS).

M.D. Gurbindo Gutierrez; P. Tornero; A. del Moral; J. Fermosel and T. Hernandez-Sampelayo.
HOSPITAL GENERAL GREGORIO MARAÑON. MADRID. SPAIN.

Serum IgE levels are increased in some congenital T cell deficiencies and autoimmune disorders. IgE synthesis is regulated by cooperation between T helper and B cells. Patients infected by Human Immunodeficiency Virus (HIV) show an early increase in serum IgG and IgA, indicating and B-cell polyclonal activation.

To determine IgE role in HIV infected children, we have measured serum total IgE (PRIST, paper immunosorbent test), normal control .values between 0.4 and 90 ui/ml, (m± 2sd), in two groups of children. 1/ In 20 HIV seropositive asymptomatic children, older than 15 months. 2/ In 17 AIDS children, P-2 status (CDC 1987).

In the first group a variable increase of immunoglobuline G and A was found, with normal serum levels of IgE. In the second group of children, serum IgG levels were between 2000 and 7000 mg/dl, IgA 200-500, and IgE level were normal, less than 90 ug/ml, in all children but one. There out of 17 AIDS patients showed hypersensitivity reaction against milk proteins, studied by specific IgE and skin test.

In conclusion, the pattern of T-cell disoder produced by HIV infection does not usually increase serum IgE levels. First type immune reactivity is preserved in HIV infected children.

T.B.P.216

EARLY DETECTION OF HIV INFECTION IN CHILDHOOD.

Castillo, Inmaculada*; Ruiz-Moreno, M.*° Omeñaca, F.**; Varas, F.*; Zamora, L.* and Carreño, V.*
* Hepatology Unit. Fundación Jiménez Díaz. UA. ** Neonatology S. Hospital Infantil La Paz. Madrid. SPAIN.

It is unclear the fiability of the anti-HIV detection in children from HIV-seropositive mothers, as the maternal antibodies and the p24 antigen (HIVAg) remain in children for a mean time of 9-10 months. For this reason is necessary to develop new diagnostic techniques for the early identification of the current HIV infection in these children. With this purpose we have studied the presence of HIV-DNA in PBMC from 17 children (mean age: 14.8 ± 8.1 months; range: 1-35 months) born from anti-HIV positive mothers, and we have compared it with the anti-HIV detection by Western-blot and serum HIVAg by EIA. HIV-DNA was detected in 10 µg of total DNA isolated from the PBMC, by slot-blot hybridization using a ^{32}P-HIV-RNA probe.

Anti-HIV was found in 11/19 (61%) of the children, circulating HIVAg was present in 2/18 (11%) and HIV-DNA in 4/18 (22%) of them. Out of the 4 HIV-DNA positive cases, 2 children (13 months each) presented anti-HIV but the HIVAg was undetectable, 1 child had anti-HIV and was also HIVAg positive, while in the remaining child (15 months) these markers were negative. All of them were asymptomatic.

In conclusion: 1) The absence of HIV-DNA in children under 1 year old could indicate that these children do not have HIV infection and the anti-HIV antibodies are from their mothers. 2) HIV-DNA detection allows the rapid diagnosis of HIV infection in asymptomatic children even without other viral markers. However, these preliminary results will be completed with a dynamic study in a wider population.

IgG SUBCLASS CONCENTRATIONS AND ANTIBODY LEVELS TO BACTERIAL TOXOIDS IN CHILDREN WITH HUMAN DEFICIENCY VIRUS (HIV)

W. Kreuz, S. Bredel, S. Zielen, T. Güngör, S. Hass, B. Wagerich
P. Bauscher P. Alvarez, S. Rehmet, D. Hofmann, B. Kornhuber
Klinikum der J. W. Goethe-Universität Frankfurt (Main) FRG

Infection with HIV leads to a combined immunodeficit. As a result of polyclonal B-cell activation there is a significant increase in the serum immunoglobulin levels. The specific humoral immune response is, however, usually impaired. We have investigated to what extent the levels of IgG subclasses undergo change as a result of HIV-infection. - In the period from January 87 to January 88 we carried out an investigation of immunoglobulin subclasses in a total of 27 children exposed to HIV. Of these children 14 had proven HIV-infection, 13 (aged over 15 month), who had been previously HIV-antibody positive, have remained negative up till the present time and have shown no clinical and immunological signs of HIV-infection. No patient was given intravenous IgG therapy before or during the investigation. The immunoglobulin, diphtheria and tetanus antibody levels of our patients were compaired to a healthy control group of 120 children of different ages. - IgG subclasses were determined by radial immunodiffusion, antibody levels to tetanus (TT) and diphtheria (DT) toxoids by enzyme immuno assay. Levels below 0,1 IE/ml were considered not to be protective for both. - In the group of 13 previously HIV-antibody positive children (now HIV-antibody negative) normal IgG subclass levels were found. In contrast, 13 of 14 HIV-positive children showed a significant increase in serum IgG1 and IgG3; 2 of them additionally showed decreased IgG2 levels. - 8 of 10 HIV infected children showed protective antibody levels to TT and 3 of 10 to DT. All non infected children had protective antibody levels to TT, but antibody levels to DT were not protective in 4.

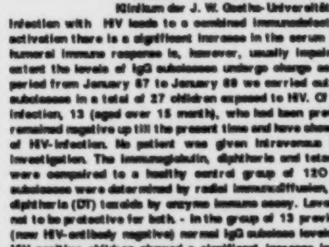
We conclude that IgG subclass abnormalities are a frequent finding in HIV-infected children especially a polyclonal increase in IgG1 and IgG3. Longitudinal observation is necessary to determine whether the development of an IgG2 subclass deficiency is an additional indication for intravenous immunoglobuline therapy. Supp.by Ministry of Health (BMJFFG, BMAS)

T.B.P.220

SEROLOGIC RESPONSE TO HIV INFECTION IN INFANTS.

Johnson, John P., Davis, E., Shinaberry R., and Nair, P.
University of Maryland School of Medicine, Baltimore, Md. USA

Objective. To document the antibody response to HIV infection in neonates.
Methods. Blood was collected from 35 children born to seropositive women at 2,4,6, and 12 months. Serum was assayed using the DuPont HIV ELISA and P24 assay. IgG and IgM Western Blots were run using strips from Organon-Technica and sequential addition of biotinylated anti-IgG (H+L) or IgM(u) followed by biotin-avidin HRPO, and then DAB.



Results. 7 children showed increasing anti-HIV IgG titer. Eleven children demonstrated IgM antibody against multiple antigens of HIV, 6 of whom showed only IgM isotype synthesis. P24 antigen was detected in 7 children. The 20 non-infected children had negative assays by 12 months.
Conclusion. The kinetics of loss of maternal antibody and the class specific anti-HIV antibody response are demonstrated in neonates.

T.B.P.217

DETECTION OF SPECIFIC IgM ANTIBODY BY RADIOIMMUNOPRECIPITATION ASSAY FOR EARLY DIAGNOSIS OF HIV INFECTION IN INFANTS

Fauvel, Micheline*, J. Lecomte**, C. Claessens*, J. Samson***, and N. Lapointe***.
*Laboratoire de santé publique du Québec, **Institut Armand-Frappier, ***Hôpital Ste-Justine, Montréal, Canada.

Objective. To evaluate IgM-specific HIV antibody (Ab) by radioimmunoprecipitation assay (RIPA) in infants born to seropositive mothers as a tool for early diagnosis.
Methods. Sequential sera from 5 HIV-infected infants were analyzed by standard RIPA with protein-A Sepharose and by RIPA-IgM. For the latter, CNBr-activated Sepharose 4B was coupled with purified monoclonal Ab to human µ-chain. Sera were incubated with anti-µ Sepharose beads and washed. (^{35}-S)HIV antigen was then added. Bound proteins were separated by SDS-PAGE and revealed by autoradiography. Specificity of IgM reactions was tested after serum adsorption on IgG-coated beads or with anti-IgG serum.
Results. IgM Ab to gp 160/120 and p24 were detected in 15/21 sera from all 5 infants. Comparison of Ab patterns observed with standard RIPA and RIPA-IgM revealed that anti-HIV IgM appeared at 8 to 13 months of age, after disappearance of maternal Ab and paralleled *de novo* Ab synthesis. IgM Ab persisted for 26-30 months in 3 children. RIPA-IgM reactivity was still observed after removal of rhumatoid factor or IgG.
Conclusion. Detection of IgM-Ab did not allow early diagnosis of HIV infection in the first months of life. Further studies are required to determine the specificity of IgM reaction in older infants.

T.B.P.219

WESTERN-BLOT QUANTITATIF : SUIVI DES NOUVEAUX-NES VIH SEROPOSITIFS

Schiavini D., Puel Jacqueline, Roussseau A., Gayet-Mengelle C.
Laboratoire de Virologie, CHU Purpan, Toulouse, FRANCE.

Objectifs. Etudier la cinétique des différentes spécificités Ac anti-VIH avec le Western-blot (WB) quantitatif chez un enfant né de mère séropositive.
Méthodes. Nous avons étudié une enfant née le 16.1.87 de mère séropositive, et qui à l'âge de 2 ans est toujours asymptomatique. Le WB quantitatif (Du Pont De Nemours) consiste en une lecture densitométrique des bandes réactives, permettant par l'obtention d'une courbe une quantification précise de chaque spécificité Ac; les résultats sont exprimés en intégrales représentatives de la surface des différents pics. Les titres d'Ac totaux (Elavia Diagnostic Pasteur) sont déterminés par comparaison de la densité optique de l'échantillon à celles d'une gamme étalon.
Résultats.

	Titres	Ac gp160	gp120	p66	p55	p51	gp41	p31	p24	p17
20.02.87	20000	4310	1214	2309	7250	1763	12770	10907	16127	18520
22.05.87	3000	3721	1928	859	604	1012	3719	3044	2639	1912
16.11.87	500	1350	276	276	0	0	0	0	851	537
10.01.88	100	531	0	0	0	0	0	0	0	0
23.09.88	100	0	0	0	0	0	0	0	0	0

Dès le 4e mois, la réactivité de toutes les spécificités Ac diminue, parallèlement à la diminution des anticorps anti VIH-1 totaux. A 1 an : les Ac anti VIH (ELISA) sont nuls; mais en WB quantitatif, les Ac gp160 persistent.
Conclusion. Ces données confirment la grande sensibilité du WB quantitatif.

T.B.P.221

THE USE OF ANTI-HIV IgM IMMUNOBLOT IN THE DIAGNOSIS OF NEONATAL HIV INFECTION : A REPORT OF 5 CASES.

Panmoung, Wattana; Sirivichayakul, S.; Chumdermpadetsuk, S.; Likitnukul, S. and Phanuphak, P.
Chulalongkorn University Hospital, Bangkok, Thailand.

Objective. To evaluate the reliability of anti-HIV IgM immunoblot in the early diagnosis of HIV infection in babies of HIV-infected mothers.
Methods. Paired maternal and cord blood from 5 babies at Chulalongkorn University Hospital from HIV-infected intravenous heroin abusing mothers were studied. Anti-HIV IgM immunoblot was modified from Pasteur commercial kits by changing the enzyme conjugates to rabbit anti-human IgM, followed by peroxidase labeled avidin-biotinylated goat anti-rabbit IgG.
Results. All newborns were anti-HIV positive at birth due to the transplacental transfer of IgG antibodies as evidenced by the identical patterns on IgG immunoblot. Using commercial ELISA kit from Diagnostic Pasteur could not be detected in any mothers or babies at birth. Anti-gp160 IgM, anti-gp120 IgM and anti-p24 IgM were found 5, 2 and 4 cord blood specimens respectively. Paired sera from 3 mothers showed weakly positive anti-gp160 and anti-p24 IgM bands. At 2-month follow-up, 2 infants developed additionalanti-gp120 IgM bands. One infant has been followed for over 6 months. Her anti-HIV IgM bands disappeared and was replaced by weakly positive anti-gp160 IgG.
Conclusion. Our preliminary study indicates that immunoblot can be satisfactorily used anti-HIV IgM to detect early HIV infection in newborns. Our results indicate that transplacental HIV infection has occured in all 5 babies studied.

T.B.P.222 IS THE IgM ANTIBODIES STATUS A USEFUL MARKER TO ASSESS THE NEONATES CONTAMINATION BY HIV-1 ?

Gayet-Mengelle C., Puel Jacqueline, Tricoire J., Rousseau A.
Laboratoire de Virologie, CHU Purpan, Toulouse, FRANCE.

Objective. Realisation of an early diagnosis of congenital or neonatal transmission in order to initiate an immediat therapy against HIV-1.
Methods. We tested IgM antibodies in 53 neonates born to intravenous drug abusers (N=45) heterosexually contaminated (N=7) and "unknown" mothers (N=1) using the Western-blot assay (Du Pont HTLV-III Western blot IgG). The test was performed at birth and/or during the clinical and biological follow-up of the neonates (mean:14,5 months). The test was considered positive when antibodies against the p24 protein were present. The results of the test were compared with the infants'parameters (clinical status, p24 antigenemia, anti p24 antibodies titers and IgG antibodies persistance beyond 18 months) and the mothers'parameters (clinical status and HIV-1 antibodies titers at the delivery).
Results. We could form 3 groups : the first included 28 children who where always IgM negative, the second group included 15 IgM positive children at a given time, and the third, 10 children with borderline results of the test at a given time. In the IgM positive group 9 children were diseased (class P2), 2 had borderline clinical status and 4 were healthy. Nevertheless, statistically significant difference was present between the number of IgM positive and IgM negative diseased children ($p < 0,02$ with IRWIN-FISHER Test).
Conclusion. The results indicate that the IgM screening may be useful as a supplementary marker in the assessment of the children contamination by the HIV-1.

T.B.P.223 ENUMERATION OF PERIPHERAL BLOOD ANTIBODY-SECRETING CELLS AS A DIAGNOSTIC AID FOR HIV INFECTION IN CHILDREN.

Nahmias,André; Lee,F.; Nesheim,S.; O'Neil, C.; Muther,J. and Slade,B. Depts. of Pediatrics and Pathology, Emory University, Atlanta, GA,USA

Objective: To evaluate the enzyme-linked immunospot (ELISPOT) for diagnosis of HIV infection in symptomatic children and infants born to seropos. mothers.
Methods: The ELISPOT, using a gP41 recombinant protein, was applied to peripheral blood mononuclear cells (PBMC) obtained from 31 negative children, 28 children with ARC/AIDS, and 27 infants born to seropos. mothers between 1985 and 1988; EIA and p24 antigen assays were also obtained.

Results:

	#tested	#HIV ASC+	# HIV ASC-
A Children with ARC/AIDS	28	20 (71%)	8 (1 with agamma.)
B Infants born to seropos. mothers	27	6 (23%)	21
C Control children	31	0	31 (100%)

HIV ASC positivity ranged from 8 to 220 per 1 million PBMC. Of the 6 ASC+ children born to seropos. women (all still EIA+), one was ASC positive at 1 mo. of age, the earliest time of ELISPOT testing in all groups (A-C). When repeated in 3 infants, the assay was positive in all three, who are now symptomatic. A fourth ASC+ symptomatic infant had virus pos. amniotic fluid in utero. Of the 21 ASC- children, 15 have been repeatedly ASC- and 9 are no longer EIA+. All infants in group B have been p24 antigen negative.
Conclusion: This rapid (<24 h) assay, which can be performed on shipped or frozen cells, appears to be specific, although its sensitivity could be enhanced by methods under current study. The HIV ELISPOT could prove particularly helpful in the early diagnosis of HIV infection in children.

T.B.P.224 RECOVERY OF HIV FROM LYMPHOCYTES AND MONOCYTES OF SYMPTOMATIC HIV INFECTED CHILDREN.

Landay, Alan L.*; Chadwick, E.G.**; Kucik, S*.; and Yogev, R.** *Rush Medical Center, Chicago, IL, U.S.A. and **Childrens Memorial Hospital, Northwestern University, Chicago, IL, U.S.A.

Objective. Correlation of immunologic and virologic findings with clinical status in perinatally HIV-infected children.
Methods. HIV antibody (Ab$^+$) and antigen (Ag$^+$) status was determined by commercial EIA procedures. CD4 and CD8 lymphocyte analysis was performed by a whole blood lysis procedure and analyzed by dual parameter flow cytometry. HIV co-culture was performed by adding peripheral blood mononuclear cells (MNC), purified lymphocytes, or purified monocytes to PHA-stimulated lymphocytes from HIV negative donors or allogeneic monocytes. Viral growth was detected by an antigen capture assay.
Results. Ten symptomatic children (3P2A, 7 P2B-F) ranging in age from 1.5 to 9.5 years were evaluated. Nine of ten were Ab$^+$ and seven of ten were serum Ag$^+$. Five of the ten patients had <300 CD4 cells/mm^3 while the CD4:CD8 ratio in nine of ten children was <0.35. Eight of ten individuals were culture positive by day three in the MNC as well as in purified lymphocytes. In contrast, co-culture of purified monocytes and allogeneic monocytes was still negative at 14 days.
Conclusions. Viral cultures were positive in the majority of symptomatic children with perinatal infection. The clinical stage of disease and immunological parameters did not correlate with viral isolation. It seems that at least in the early phase of culture, HIV grows more readily from lymphocytes.

T.B.P.225 NEOPTERIN - POTENTIAL EARLY MARKER OF PERINATAL HIV INFECTION

Lischner, Harold W*; Bagasra, O**, Raphael, SA*, Treston, CS*, Shandilya, L**. *Temple Univ & St Christopher's Hosp for Children, Philadelphia, PA; **Univ of Med. & Dent. of New Jersey, Camden, NJ,USA.

Objective. To test the hypothesis that neopterin (N) levels can differentiate infected from non-infected infants and children of HIV-infected mothers.
Methods. N was determined by ^{125}I radioimmunoassay (DRG, Berlin) in 58 serum and/or EDTA plasma specimens from 40 children of HIV-infected mothers 1 to 39 mo of age and control specimens. ↑N was taken as >3 SD above adult mean.
Results. Mean N levels in ug/ml are shown by CDC diagnostic class at writing:

	N ± SD	n	n with ↑N
Probably not infected (HIV antibody negative)	6.3 ± 2.1	12	0
CDC P0 (indeterminate - HIV cultures pending)	9.9 ± 4.4	15	5 (15 ± 3 ug/
CDC P1A or B (infected - asymptomatic)	19 ± 4	2	2 ml)
CDC P2A (infected - "ARC")	8 ± 3	4	1 (11 ug/ml)
CDC P2B, C, and/or D (infected - "AIDS")	37 ± 19	7	7

N levels in replicate specimens obtained 3 to 9 months apart were usually (in 11 of 18 pairs) within one SD range (4.1 ug/ml) of replicate assays on the same specimen. In 4 HIV-infected infants and one infected 3 yr old, rises of 5 to 19 ug/ml were observed. In 2 infants, now antibody negative, falls of 6 to 8 ug/ml were observed. N levels were high (24 ± 11) in presumably normal umbilical cord sera, but appeared to reach adult levels by 1 mo of age. Urine N levels appeared to be less discriminatory than plasma levels.
Conclusion. The pilot data support the hypothesis for asymptomatic infants only, suggest that N levels may be useful in staging perinatal HIV infection, and indicate that a hypothesis (Clin Immunol Newsletter 9:197, 1988) that ↑N release occurs in primary HIV infection deserves investigation in infants.

T.B.P.226 HIGH PREVALENCE OF HIV-SPECIFIC IgA AND IgG-SPECIFIC IgM ANTIBODIES IN NEONATES OF HIV-POSITIVE MOTHERS.

Schüpbach, Jörg*; Wunderli, V.**; Kind C.***; Kernen, R.*; Baumgartner, A.*; Tomasik, Z.*.
* Swiss National Center for Retroviruses, Institute of Immunology and Virology, University of Zurich, Zurich, Switzerland
** Institute of Immunology and Virology, University of Zurich, Zurich,
***Swiss Neonatal HIV Study Group, Department of Neonatology, Kantonsspital, St.Gallen, Switzerland

Objective. To analyse the specificity of Western blot (WB)-reactive IgM and IgA in cord bloods.
Methods. Cord blood of 21 babies of HIV$^+$ mothers was tested for HIV-specific IgM or IgA by WB. Preabsorptions of IgG with immobilised protein A or G were done to determine whether reactions were mediated by HIV-specific IgM or IgA, or by such antibodies bound to HIV-reactive IgG of maternal origin.
Results. Initial IgM reaction was present in 15 sera (71%). Removal of IgG showed that 80% of these IgM were directed against maternal HIV-specific IgG. IgA reaction was present in 10 sera (48%); absorption of IgG indicated HIV specificity in 8 (38%). Most IgA reaction was seen only after removal of bulk IgG. Absorption with immobilised protein G was better than with protein A. Antigen was present in 1/21, in a case negative for IgM or IgA.
Conclusion. Most HIV WB-reactive IgA are indeed HIV-specific; most HIV WB-reactive IgM are specific not for HIV, but maternal IgG.

T.B.P.227 PROSPECTIVE STUDY OF POLYMERASE CHAIN REACTION FOR EARLY DETECTION OF HIV INFECTION IN INFANTS BORN TO HIV ANTIBODY POSITIVE WOMEN

Weintrub, P.; Ulrich, P.; Edwards, J.; Rumsey, C.; Vyas, G.; Cowan, Morton et al.
University of California, San Francisco, California USA

OBJECTIVE. To determine the applicability of polymerase chain reaction (PCR) for early diagnosis of HIV infection in high-risk infants.
METHODS. All infants referred for prospective evaluation who were ≤3 months of age and born to HIV antibody positive women were studied. For PCR, amplifications using 2 distinct gag specific primer pairs were performed on crude PBMC lysates for 35 cycles. Hybridization in solution to a P32-labeled oligomer probe was followed by polyacrylamide gel electrophoresis and autoradiography. Specimens were tested at least twice with each primer pair. HIV culture was performed on all specimens by standard co-culture technique.
RESULTS. Thirteen infants were tested at a mean age of one month. Three infants were positive by PCR for every amplification. Only 2 of these were HIV culture positive. Three infants were equivical by PCR (<100% positive amplifications). All 3 were HIV culture negative. All 7 PCR negative infants were also HIV culture negative. No patient was HIV culture positive and PCR negative. All patients are well (mean age 7 months) and being followed.
CONCLUSIONS. PCR is applicable for the early detection of HIV infection in high-risk infants and appears to be more sensitive than standard co-culture technique. Long-term follow-up is essential to determine if PCR positive and equivical infants who are culture negative are truly infected or represent lack of specificity.

T.B.P.228

HIV p24 ANTIGEN ASSAY AS A DIAGNOSTIC/PROGNOSTIC TEST IN PEDIATRIC HIV INFECTION.

Silva, Tom J., Olson, B., Simpson, B.J., Andiman, W.A. Yale University School of Medicine, New Haven, CT. USA

Objective. To learn if HIV p24 antigen (Ag) detection tests can be used to diagnose infection in children or to select mothers at risk of transmitting infection.
Methods. We examined sera from a group of children born to HIV seropositive (HIV+) women as part of an ongoing prospective study of pediatric AIDS. We used a commercially available p24 capture immunoassay (Abbott) to screen 109 serum samples from 66 children; sera from 48 of their mothers were also examined. "Infection" was defined by CDC criteria.
Results. Nine of 66 children of HIV+ women and 3 mothers were Ag+. Seven of 8 infected children were Ag+, but only 12 of 19 individual samples were Ag+. One of 41 seronegative children was Ag+. When the incidence of antigenemia in mothers and children was compared we found that 9% of Ag- mothers had Ag+ children and that only 1 of 6 children who met CDC criteria for infection had an Ag+ mother. In 2 of 9 instances the inverse relationship between Ag and p24 antibody detected by Western blot did not exist. Antigenemia occurred at a higher rate in symptomatic/infected than in asymptomatic/uninfected children. The p24 Ag assay failed to identify 1 of 8 children with symptoms. Only 7 of 19 tests in symptomatic children were positive; thus, serial tests may be needed to identify an Ag+ patient.
Conclusions. The clinical utility of a single negative p24 test is low. It does not classify a child as uninfected and it does not predict a more benign disease course. A negative Ag test in a mother does not necessarily indicate that her child will be Ag-.

T.B.P.229

SEQUENCIAL IN PARALLEL STUDY OF HIV INFECTED MOTHERS AND THEIR CHILDREN SINCE THE NEONATAL PERIOD AGE.

L.PEREZ ALVAREZ; *M.D.GURBINDO; L.MUÑOZ; *T.HERNANDEZ-SAMPELAYO; J.M.VARELA; A.GARCIA et Al.
INSTITUTO DE SALUD CARLOS III; UNIDAD DE SIDA. *HOSPITAL GENERAL GREGORIO MARAÑON.MADRID.SPAIN.

Objectives.Sequential follow up of HIV antibodies in mother-child pairs since birth and the analysis of the evolution of the bands against the different viral proteins by WB technique.
- Study of the potential usefulness of the P-24 Ag analysis as suggestive marker of neonatal infection.
- Confirm the existence of HIV virus in infants younger than 15 months by lymphocytes cultures.

Methods.Since january 1.988 we have studied 10 pairs mother-child,every 3-6 months since the first quarter of life. Serum samples were tested by different EIA methods,IFA and Western Blot, and P-24 antigen was detected by EIA.Viral isolation has been attempted by co-culturing peripheral blood lymphocytes.
Results.All the mothers are intravenous drug addicts and HIV+.All the children are asymptomatic in PO stage. In relation with the sequential analysis until now,4 children turned seronegative and in other four there was a gradual disappearance of the bands detected by WB.The final and conclusive data will be supplied at the end of the study now in progress.P-24 Ag was detected only in one mother whose child turned seronegative at the age of 12 months. Until now the virus isolation has been negative in all cases.
Comments.Perhaps could be possible to confirm the presence of HIV infection in the early 15 months of life by the serial analysis with WB of the sera of children of mothers HIV+ since birth,and bt the detection of P-24 Ag, although the final diagnostic at this age involve the virus detection, re [illegible] it is very useful the virus isolation from lymphocytes and the DNA detection.

T.B.P.230

COMPARISON OF THE ORTHO HIV RECOMBINANT ANTIGEN NEUTRALIZATION ASSAY AND DUPONT WESTERN BLOT FOR CONFIRMATION OF ELISA REACTIVE SERA FROM CHILDREN

Frost, Andra*; Mohla, C.**; Luban, N.** and Campos, J.**.
*George Washington University Hospital, Washington, DC, USA, **Children's Hospital National Medical Center, Washington, DC, USA.

Objective. To compare the performance of the HIV Recombinant Antigen Neutralization Assay (RANA) (Ortho Diagnostic Systems, Raritan, NJ, USA) and the HIV Western Blot Kit (WB) (DuPont Company, Wilmington, DE, USA) as confirmatory tests of HIV ELISA repeatedly reactive sera from high-risk children.
Methods. RANA uses a pool of recombinant core (p24), polymerase (p31) and envelope (gp41) antigens for neutralization of HIV antibodies in ELISA positive sera. Dilutions of reactive sera were added to the antigen mixture and incubated for 16-18 hours at 37°C. The ELISA reactivity (Abbott HIV EIA, Abbott Laboratories, North Chicago, IL, USA) of each neutralized serum was determined and compared to an unneutralized control. A reduction in absorbance by ≥40% constituted a positive test. WB was performed and interpreted according to the manufacturer's instructions.
Results. All 34 study sera were positive by RANA (mean neutralization 72%), and 25 (74%) were positive by WB. Nine sera (26%) yielded indeterminate WB results. Of the nine, 6 were tested for HIV antigen (Abbott HTLV III Antigen EIA) and 4 were positive. None of the HIV ELISA repeatedly reactive sera collected from our high-risk population during the study period was RANA or WB negative.
Conclusion. RANA is a sensitive, objectively interpreted confirmatory test of HIV ELISA seropositivity in high-risk children.

T.B.P.231

A NOVEL HIV 1 EIA DETECTS IgG AND IgM ANTIBODIES IN ADULTS AND NEONATES.

Baccard-Longere, M.*; Blanc, Sylvie**; Genoulaz, O*; Giroud, M*; Seigneurin, J.M*.
* Department of virology, A. Michallon Hospital, BP 217 X,38043 Grenoble Cedex France; ** Wellcome Diagnostics, F 75640 Paris cedex 13, France.

Objective.To study the utility of the Wellcozyme HIV Recombinant EIA in HIV Diagnosis, and in particular its ability to detect IgM antibodies in infants.
Methods. The EIA was initially evaluated on 4000 sera and 500 positive samples, including 12 sera from individuals at the beginning of sero-conversion. IgM antibodies were isolated by sucrose gradient centrifugation and their presence confirmed by Western Blotting.
Results. The assay's specificity is near 100%. No false positives were detected in the negative samples nor in 25 samples known to give falsely positive results in other EIA. All the positives samples were detected, including those from sero-convertors whose blots would not yet have been declared positive : presence of antibodies to P24 and GP160 or indeterminate, and a specimen in early sero-conversion for HIV 2. IgM was detected in 25/35 samples, and in the stored samples 1 of 2 infants known to have been infected perinatally (cord blood was IgM negative) but not in non-infected of infants of sero-positive mothers.
Conclusion. This EIA is specific ans sensitive - useful for detection of early sero-conversion in adults and neonates as well as for routine screening.

T.B.P.232

IgM MAY BE DIRECTED TO CONFORMATIONAL EPITOPES EARLY IN SEROCONVERSION TO HIV.

Robert Gregg*, Smith G**, Wayner E*, Pollock L* and Epstein JS*.
*FDA, Bethesda, MD; **MicroGeneSys, Inc., West Haven, CT, USA.

Objective. To determine if the apparent insensitivity of a whole virus immunoblot (WB) to early anti-HIV IgM in seroconversion series is a function of conformation or mass of epitopes available in that format.
Methods. Anti-HIV detection by WB (DuPont) and a recombinant gp160, p24 immunoblot (rBlot) were compared using class-specific anti-human Ig conjugates. Parallel studies were performed with a rEIA using native or SDS,2ME-denatured proteins coated in equal amounts to 96-well plates.
Results.

ANTIBODY SPECIFICITIES IN EARLY BLEEDINGS

	DuPont WB strips		MicroGeneSys-rBlot	
Subjects	IgG	IgM	IgG	IgM
1	NONE	NONE	GAG	ENV
2	GAG	NONE	ENV	ENV
3	GAG	NONE	GAG,ENV	ENV
4	GAG,ENV	NONE	GAG,ENV	NONE

In general, O.D. values were lower for denatured than for native rEIA. In early bleeds of 3/4 subjects, the values actually fell below cut-off.
Conclusions. We demonstrated increased sensitivity of the rBlot vs the WB due to improved detection of the early IgM response with full-length native recombinant protein; more so ENV than GAG. The parallel rEIA study clearly showed that denaturation reduced signal strength. These results suggest that conformational epitopes may be important for IgM detection; epitopes that are lost in WB format. These observations may be important in improving early antibody detection and in evaluating vaccines.

T.B.P.233

HYPERGAMMAGLOBULINEMIA AND HYPOGAMMAGLOBULINEMIA AS MANIFESTATIONS OF HIV DISEASE IN PERINATALLY INFECTED CHILDREN

Calvelli, Theresa; Steinhauer, E.; Pathak, R.; Davydov, V.; Bernstein, L. and Rubinstein, A.
Albert Einstein College of Medicine, Bronx, New York, U.S.A.

Objective. Diagnosis of HIV infection in children born to HIV positive mothers can be complicated as a result of infant B cell dysfunction even after disappearance of maternal antibody. In our experience, 8% of children presenting with symptomatology consistent with HIV infection show negative or equivocal ELISAs and Western Blots.
Methods. To ascertain whether the absence of reactivity in HIV antibody tests in HIV infected infants was due to (1) an inability to produce immunoglobulin, or (2) an inability to form specific antibody responses, serum from each child was assayed for IgG concentration. Standard radial immunodiffusion assay was employed.
Results. Eight of 20 HIV infected but serologically negative children were found to be hypogammaglobulinemic. None of these yielded an unequivocal positive specific HIV antibody test on multiple drawings through 1 year of follow up. Thirty percent were found to have normal serum IgG concentration, and 15% were low normal; of these, 1 eventually seroconverted. Three were hypergammaglobulinemic. None of these have seroconverted for as long as 1 year of follow-up (up to 3 years of age).
Conclusions. Negative or equivocal antibody tests in children who are perinatally infected with HIV can be the result of at least 2 distinct manifestations of B cell dysfunction. Some children, despite their ability to produce IgG, are unable to mount a specific antibody response to HIV; others may also be hypogammaglobulinemic.

T.B.P.234 ASSOCIATION BETWEEN PLASMA HUMAN IMMUNODEFICIENCY VIRUS TYPE-1 (HIV) VIREMIA AND CLINICAL CLASS OF PEDIATRIC HIV INFECTION

Burchett, Sandra, Coombs, R., Chaloupka, K., Stamateou, J., Wilson, C., Corey, L., et al. University of Washington, Seattle, WA, USA.

Objective. To develop sensitive virologic markers predictive of asymptomatic and symptomatic pediatric HIV infection.
Methods. Sequentially obtained samples from 12 HIV infected children as they progressed from CDC classification P1 to P2 and from 15 PO children were analyzed. Plasma or peripheral blood mononuclear cells (PMBC) from 3-5 ml of blood were cultured ≤28 d. P24 antigen (Ag) in culture supernatants or in plasma/serum was determined by EIA antigen capture (Abbott).
Results.

	Onset P1 Diagnosis		Onset P2 Diagnosis	
	Perinatal	Transfusion	Perinatal	Transfusion
n	6	6	5	2
Age mean (mo.)	8	96	12	82
range	0-18	74-132	2-36	80-84
PBMC	4/4	4/5	5/5	2/2
Plasma	0/4	0/5	5/5	2/2
Ag	2/4	2/4	5/5	1/1

All PO children remained asymptomatic, PBMC culture neg. and Ag neg.
Conclusion. HIV PBMC culture and Ag were highly sensitive (94%) for detecting infection. While Ag was associated with both P1 and P2 infection (p=NS). HIV plasma viremia was only associated with P2 infection (p=0.003). The association between plasma viremia and symptomatic stage of infection suggests there is an increased amount of replicating HIV associated with advanced clinical disease. Plasma viremia is a potential endpoint for evaluating both progression of disease and antiviral therapy in the pediatric population.

T.B.P.235 DETECTION OF HIV SEQUENCES IN CHILDREN BORN TO SEROPOSITIVE MOTHERS.

Borghi*, Vanni; Selleri**, L.; Lami*, G.; Frigieri***, G.; De Rienzo*, B.; Torelli**, G.
Department of Infectiuos Diseases*, Dpt of Internal Medicine and Haematology** Dpt of Pediatric***; University of Modena, Modena, Italy.

Purpose: Early detection of HIV infection in children born to seropositive mothers is now possible utilizing the polimerase chain reaction (PCR).
Methods: PCR was performed on DNA extracted from PBMCs of children born to seropositive mothers as described by Saiki et al. using the SK 68 - SK 69 primers and the SK 70 probe, homologous to the HIV envelope. Clinical condition of the children were assessed following the criteria of Brunett-Lezine and Bayley, and by immunological and virological tests.
Results: 13 children have been followed from birth, all were born to seropositive IVDA mothers. All children were seronegative at the moment of DNA extraction. The loss of maternal anti-HIV Ab IgG occurred in 10-19 months after birth. None of the children was clinically or immunologically immunocompromised. The PCR was performed in 4 children (age 12-36 months) apparently healthy. Amplification of the envelope fragment identified by the SK 68 and SK69 primers occurred in all 4 cases.
Discussion: The PCR is an early diagnostic test for HIV infection in children and it can offered a precious tool as serological diagnosis is not possible in newborn children for several months after birth.

T.B.P.236 LYMPHOKINE AND IMMUNOGLOBULIN PRODUCTION IN VITRO IN NEONATES AND INFANTS WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION

Prieto, Cecilia; Hanson, I.C., Hansen, T.N. and Shearer, W.T. Baylor College of Medicine, Texas Children's Hospital, Houston, TX, USA.

Objective. To assess early immune parameters in HIV+ neonates and infants.
Methods. Interleukin-2 (IL-2) was measured using an IL-2 dependent cell line (CTLL) after stimulation with PHA and augmentation with recombinant IL-2 in placental (Con 1) and infant (Con 2) controls and HIV+ neonates and infants. Immunoglobulin production after PWM stimulation and 7 day incubation was measured in affected children and described controls.
Results. HIV+ infants studied were Group 1, < 8 weeks (asymptomatic [n=4], coinfected with cytomegalovirus (CMV) [n=2]) and Group 2, > 1 year [n=16]. IL-2 results are reported as units/ml (mean±standard error).

	Group 1(asy)	Group 1(CMV)	Con 1	Group 2	Con 2
PHA [50ug/ml]	0.11± 0.09	2.0± 0.5*	0.17± 0.08	0.14± 0.12*	0.37± 0.16
IL-2[500u/ml]	1.33± 0.68*	Not done	5.57± 1.49	2.34± 1.49	5.10± 2.48

* p less than 0.05

IgM production after PWM and PWM+IL-2 stimulation was negligible in Groups 1 and 2 and Con 1 compared to adult controls. IgG production was high in 3 infants in Group 2 alone.
Conclusions. IgM production in vitro for HIV+ neonates and infants is not different than expected neonatal results. IL-2 production was decreased except in those infants with concurrent CMV. Monitoring IL-2 production with clinical correlation may detect subtle immune changes in HIV+ children.

T.B.P.237 EARLY DETECTION OF HIV-1 SEROCONVERSION IN INFANTS OF SEROPOSITIVE MOTHERS USING SERIAL DILUTIONS IN WESTERN BLOTTING.

Barnes, Sandra*; Alexander, S.**; Young, M.*; Olopoenia, L.*; Manak, M.**; and Frederick, W.* *Howard University Hospital, Washington, DC. U.S.A. **Biotech Research Laboratories, Rockville, Maryland, U.S.A.

Objective. To determine if serial dilutions in Western blot (WB) assay can distinguish HIV-1 seroconversion from passively transferred maternal antibody (Ab) in infants born to seropositive mothers.
Methods. Sequential serum samples collected at 3-month intervals on 17 male and 9 female infants were tested by standard ELISA (ENI). Samples were also tested for HIV-1 Ab using serial dilutions of 1:100, 1:500 and 1:1000 in a standard WB assay (Biotech), and for p24 antigen (Ag) by EIA (Abbott). Polymerase chain reaction (PCR) was performed on lymphocytes from 22 infants.
Results. All infants were seropositive at birth by ELISA and WB assays. Among infants who later became seronegative (Sn), the mean age from birth to nonreactivity was 9.8 mos. Serial serum dilutions in WB demonstrated disappearance of significant maternal Abs with emergence of infant Ab patterns typical of seroconversion in 7/26 infants at a mean age of 7.4 mos. At this age no difference was observed in Ab reactivity using standard ELISA and WB assays between the 7 seroconverters and the remaining 19 infants whose sera were still reactive by standard WB assay (1:100 dilution), but who later became Sn. Among the seroconverters, p24 Ag was detected just prior to seroconversion in 4 infants. PCR was positive in only 3. Currently 1/7 has AIDS, 2/7 have ARC.
Conclusions. Serial serum dilutions in WB assay detected seroconversion in infants of seropositive mothers at an earlier age than standard ELISA and WB assays. P24 antigenemia preceded HIV seroconversion. PCR positivity did not correlate strongly with seroconversion in our study.

T.B.P.238 DETECTION OF SECRETORY ANTIBODIES TO HIV IN NEONATES

Archibald, David; Nair, P.; Hines, S.; Davis, E.; & Johnson, J.
University of Maryland at Baltimore, Baltimore, MD, U.S.A.

Viral-specific, non-maternally derived secretory IgA (sIgA) antibodies have been demonstrated soon after birth in certain infections. SIgA to HIV antigens has been detected in infected adults. We collected serum and saliva from 21 children (ages 2 to 48 months) born to women at risk for HIV infection to investigate the presence of HIV-specific salivary IgA. HIV infection was ascertained by one or more of the following: a rise overtime in serum ELISA titre, development overtime of IgG antibody to new HIV antigens, positive p24 antigen or PBL culture, or demonstration of serum IgM by Western Blot (WB) to 2 or more different classes of HIV antigens. Saliva samples were assayed for HIV-specific antibodies using an IgA-specific WB. Saliva from 7 of 10 infected children, including one aged 6 months, demonstrated IgA class antibodies to HIV envelope antigens; 4 of the 7 also showed sIgA antibodies to other HIV antigens. The 3 sIgA negative infected children all demonstrated decreasing or absent serum IgM and IgG responses to HIV at the time of saliva sampling. Six of 6 children born to negative mothers were IgA negative. Five children (2 to 6 months) with indeterminant HIV status, born to infected mothers, showed no viral-specific sIgA, nor did they show serologic evidence of HIV infection. HIV-specific sIgA was detectable at 6 months of age and may prove to be valuable in the diagnosis of HIV infection in children born to infected mothers.

T.B.P.239 ANEMIA AND HYPERGAMMAGLOBULINEMIA IN INFANTS WITH PERINATAL HIV INFECTION

Walsh, Gregory; Hutton, N. and Modlin, J. Department of Pediatrics, Johns Hopkins University School of Medicine, Baltimore, Maryland. U.S.A.

Objective: To determine whether hematologic abnormalities or hypergammaglobulinemia are early indicators of HIV infection in infants born to HIV infected mothers.
Methods: Complete blood counts and immunoglobulin concentrations were obtained from 20 five to nine month old infants born to HIV infected mothers and who were either asymptomatic or had nonspecific clinical signs and symptoms. These laboratory values, as well as aspects of the clinical history, were compared between the 8 infants who eventually met CDC criteria for HIV infection and the 12 infants who seroreverted.
Results: A significantly lower mean hematocrit value (32.5) was found for the infants who later met CDC criteria for perinatal HIV infection compared to the infants who seroreverted (37.6). Elevated mean immunoglobulin levels were also noted in infected infants (infected: IgG = 2840, IgA = 399, IgM = 268; noninfected: IgG = 480, IgA = 27.3, IgM = 81). No aspect of the history could explain these differences.
Conclusion: Unexplained anemia or hypergammaglobulinemia in an infant with indeterminate (CDC class P-0) HIV status strongly suggests the presence of HIV infection.

T.B.P.240 ELISA (E) AND WESTERN BLOT (WB) PATTERNS AND A POSSIBLE MARKER OF SEROREVERSION (SR) IN INFANTS BORN TO SEROPOSITIVE (SP) WOMEN.

Mendez, Hermann*, Holman, S.*, Stevens, R.**, Wethers, J.**, Minkoff, H.*, Landesman, S.*, et. al.***. SUNY-HSCB, Brooklyn, N.Y., **New York State Labs, Albany, N.Y., and ***NIH., Bethesda, Maryland, USA.

OBJECTIVE: To describe HIV serological responses and to identify predictors of infection or SR in infants born to SP mothers.
METHODS: Pre and post-partum maternal sera, and infant sera collected at birth and at 3 months intervals, were frozen and later tested by E (Dupont) and WB (Organon-Teknika) against known controls.
RESULTS: Sera from 32 mother-infant pairs (infants' mean age: 20.5 mos; 6.9 specimens per child) were available. Generally, the infants' initial WB pat'erns reflected the mothers' prepartum. By clinical and lab criteria, 9/32 infants were infected; 8/9 had serially reactive (R) E, 1/9 became non reactive (NR) before developing AIDS. WB of infected infants showed fading of bands with subsequent increased reactivities and appearance of new bands. In 21 of the remaining 23 infants a NR E preceded a NR WB mainly due to fading but persistent anti-p24. In 4/23 (ages 15,18,19, and 24 mos) WB was equivocal. Seroreversion occurred in 14/19 before 15 mos, and 5/19 after 15 mos of age. Once E and WB became negative all infants remained negative. An anti-gp120 band was present in the maternal samples and the infants first WB in 14/19 (74%) seroreverters and in 2/9 (22%) infected infants($p \le 0.001$)
CONCLUSION: The presence of anti-gp120 detected late in pregnancy and in the newborn, may be a marker of subsequent seroreversion.

T.B.P.241 SEQUENTIAL WESTERN BLOT PATTERNS IN CONFIRMED HIV SEROPOSITIVE INFANTS

Luban, Naomi L.C.; Criss, V.C.; Joseph, S.; Mohla, C.; and Campos, J.M.
Children's Hospital National Medical Center, George Washington University School of Medicine, Washington, DC, USA.

Objective. To follow western blot patterns over time in confirmed HIV seropositive infants and compare loss of specific bands with the Centers for Disease Control classification of disease.
Methods. One hundred eighty-five serial serum specimens were collected at approximate 3 month intervals from 37 confirmed seropositive infants (<24 months of age) and tested for ELISA reactivity (Abbott HIV EIA, Abbott Laboratories, North Chicago, IL, USA), western blot (HIV Western Blot Kit, Dupont Company, Wilmington, DE, USA) and HIV antigen (Abbott HTLV III Antigen EIA). Each infant also was evaluated according to the Centers for Disease Control classification scheme for pediatric AIDS.
Results. Eight of the 37 infants (21.6%) became western blot negative during the study period, at a mean age of 16 months (range 12-23 months). Nine of the infants remained western blot positive; 3 of the 9 were HIV antigen positive. Twenty of the infants became western blot indeterminate; 6 of the 20 had class P2 disease, and 5 of the 6 were HIV antigen positive. Inconsistent western blot patterns were observed in these 5 infants over time and among infants.
Conclusion. Western blot indeterminant patterns are common in infants with HIV disease. Retention and/or disappearance of specific bands in serial western blots from confirmed HIV seropositive infants are not as prognostically useful as reported in adults. The definition of "indeterminant" may need to be redefined in infants with perinatally acquired HIV.

T.B.P.242 EVALUATION OF THE WESTERN-BLOT IgM TECHNIQUE SPECIFICITY

Gayet-Mengelle C., Rousseau A., Puel Jacqueline
Laboratoire de Virologie, CHU Purpan, Toulouse, FRANCE

Objective. Evaluation of the western blot IgM technique specificity.
Methods. During the virological screening of seropositive intravenous drug abusers women (N=67) and infants born to seropositive mothers (N=20) we investigated the IgM status by the Western Blot assay (Du Pont HTLV-III Western blot IgM). The test was considered positive when the presence of antibodies against the p24 protein could be detected. When the IgM antibodies were present, the specificity of the reaction was checked by comparing the results before and after elimination of the rhumatoid factor by the "RF Sorbent"(Behring Laboratory) and after the IgG-IgM separation by elution through DEAE cellulose micro-columns.
Results. Although IgM antibodies were detected in 35 serum specimens, the specificity could be tested upon 24 sera only. In 11 cases the obtained results were identical. In 13 cases the results were dissociated :
.3 sera were negative after the elimination of the rhumatoid factor that could give a false positive result with the two first techniques.
.9 sera were negative after elution through the micro-columns. The dilution of the specimens during this treatment could explain this negativity.
.1 serum was negative after both : the result obtained for the serum before treatments could probably represent a false positivity.
Conclusion. IgM antibodies were really present in 20 sera. Thus the specificity of the Western-blot technique is high (83,33 %) and it can be a useful test in the neonates follow-up.

T.B.P.243 MONITORING OF HIV ANTIBODY PROFILES BY RIPA AS A MEANS OF DIAGNOSING INFECTION IN INFANTS

Fauvel, Micheline*, J. Samson**, G. Delage**, N. Boucher**, and N. Lapointe**.
*Laboratoire de santé publique du Québec. **Hôpital Ste-Justine, Montréal, Canada.

Objective. In an ongoing prospective study of HIV perinatal infection, radio-immunoprecipitation assay (RIPA) was evaluated for its ability to differentiate de novo synthesis from passively transferred antibody (Ab). RIPA was also compared with virus isolation and HIV antigen (Ag) detection for early diagnosis.
Methods. Fifty-two sera obtained at each visit from 9 asymptomatic mothers and 6 infants were tested for HIV-Ab by RIPA and for HIV-Ag with a commercial EIA. Isolation was carried out by co-culture of PBL with cord blood lymphocytes and was monitored by RT activity and HIV-Ag detection.
Results. Sera of 8/9 mothers revealed Ab profiles against all labelled HIV polypeptides by RIPA. Virus was isolated in 6/7 women. HIV-Ag was demonstrated in only one. Initial sera from infants did not show Ab profiles different from those of their mothers. Analysis of sequential sera obtained up to 9 months of age revealed decreased reactivity to selected polypeptides, indicating loss of maternal Ab. Virus was isolated from 3 symptomatic infants (at 14 d, 2 m and 5 m), but not from 3 asymptomatic ones. HIV antigenemia was observed in only one symptomatic infant.
Conclusion. Our preliminary results support that virus isolation is a more sensitive indicator of HIV infection than Ab or Ag detection. Comparison of Ab profiles in sera of women at birth and their offspring did not allow early diagnosis of HIV infection in infants.

T.B.P.244 EARLY DIAGNOSIS OF HIV-INFECTION IN CHILDREN BORN TO SEROPOSITIVE MOTHERS:CRITICAL EVALUATION OF NEW DIAGNOSTIC APPROACHES.

De Rossi A.*,Amadori A.*,Giaquinto C.*,Del Mistro A.*,Mammano F.*,Zacchello F.*,Chieco-Bianchi L.*
*Institute of Oncology,*Dept.of Pediatrics, University of Padova, Padova, Italy

Objective. Develop a protocol for early diagnosis in children born to HIV seropositive mothers. Correlation between diagnostic results and HIV infection status.
Methods. Children born to seropositive mothers were studied at birth and/or in the first months of life for the following parameters: 1)in vitro production of antibody, 2) antigenemia in sera, 3) virus culture assay, and 4) DNA amplification by polymerase chain reaction using specific primers for gag and env HIV genome.
Results. In a series of 101 children, 64 were repeatedly negative for all parameters and 18 were constantly positive; in 19 cases the results were discordant among different tests. More than one year follow-up of the negative children later confirmed that all, but one who developed AIDS at, 6 mos. of age, were not infected; 10 of the 18 positive children developed AIDS or AIDS related symptoms. Among the discordant cases, several patterns were observed, and the 4 parameters were variously positive and negative, in different combinations.
Conclusions. Analysis of the data provided the limits of the single diagnostic procedures, and also reflected the different status of HIV infection; interestingly, 2 asymptomatic seronegative, but HIV infected children, were identified.

T.B.P.245 INTERET DE LA MISE EN CULTURE SYSTEMATIQUE DU VIH CHEZ LES ENFANTS NES DE MERES INFECTEES

Fleury, Hervé J.A.*; Delord, B.*;Douard, D.**;Perel, Y.**; Nicheau, N.**; Contraires, B.***.
* Laboratoire de Virologie, CHR de Bordeaux et Université de Bordeaux II, Bordeaux, France.
** Services de Pédiatrie et Néonatalogie, CHR de Bordeaux, Bordeaux, France.
*** Service de Pédiatrie, Centre Hospitalier de la Côte Basque, Bayonne, France.

Objectif. Comparer les résultats de la mise en culture systématique du VIH aux autres données biologiques et cliniques dans une cohorte prospective de 30 enfants nés de mères infectées.
Méthodes. Les cellules mononucléées du sang circulant d'enfants nés de mères infectées par le VIH 1 ont été systématiquement mises en culture et le virus VIH 1 éventuellement produit a été détecté par son activité RT et la présence de l'antigène de Core p24. Les résultats de l'isolement ont été confrontés aux données de l'antigénémie VIH 1, de la cinétique des anticorps anti-VIH 1 (ELISA et WB), de la numération des lymphocytes TCD$_4$, du dosage sérique des immunoglobulines et de l'état clinique.
Résultats. Nous distinguons deux groupes : l'un où l'isolement viral est négatif et dont les autres données biologiques et cliniques indiquent qu'il n'y a pas d'infection virale ; l'autre (≃ 30 % des enfants) où l'isolement est positif et corrélé par un ou plusieurs paramètres péjoratifs (antigénémie positive, augmentation des immunoglobulines, signes cliniques .../...).
Conclusion. L'isolement systématique du VIH chez les enfants nés de mères infectées demeure une technique de base indispensable à l'établissement d'un pronostic.

T.B.P.246 INFUSION OF ANTI P24 ANTIBODY RICH PLASMA IN TWO CHILDREN WITH PERSISTENT HIV ANTIGENAEMIA - A PILOT STUDY

Rosemary Hague*; PL Yap ; JYQ Mok*; GG Jackson^; PD Hargreaves+;MA Coutts" *City Hospital,Edinburgh; S E Scotland Blood Transfusion Service,Edinburgh; ^London Hospital Medical College; +Regional Virus Lab, City Hospital,Edinburgh; "Royal Inverclyde Hospital, Greenock UNITED KINGDOM

Objectives; To study the clinical and laboratory sequelae of passive immunotherapy with plasma rich in anti p24 antibody on 2 children with persistent HIV core antigenaemia and seronegative for anti p24 antibody.
Methods; Plasma was harvested as previously described (Lancet 1988 ii647-652). The 2 children aged 5 and 4, had a history of recurrent bacterial infections, failure to thrive and declining T4 lymphocyte counts. They were already receiving normal immunoglobulin infusions 200mg/kg every 3 weeks and one child had recieved zidovudine, but had discontinued because of recurrent myelosuppression. Anti p24 plasma was given at a dose of 2mls/kg 6 weekly.
Results; Both patients remained clinically stable, and T4 lymphocyte counts also stabilised. Antigen was undetectable 2 hours after completion of the infusion. The table documents the subsequent progress

Time post infusion	0	2hrs	2 days	1 wk	2 wks	3 wks	4,5 wks	6 wks
Core index (Abbott)	1,54	0,04	0,1	0,3	0,54	0,9	1,09	1,4
Antigen (Abbott)	>750	-	-	-	104	170	475	>750

Conclusion; Plasma rich in anti p24 antibody is effective in eliminating core antigen. However on this regimen no sustained loss of antigen was demonstrated. Further studies are required to define the optimum dosage and frequency of infusions to provide prolonged suppression of antigen, as it is likely that this will be necessary before clinical benefits become apparent.

T.B.P.247 DIDEOXYCYTIDINE (DDC) ALONE AND IN COMBINATION WITH AZT FOR CHILDREN WITH SYMPTOMATIC HIV INFECTION A PHASE I EVALUATION

Pizzo, Philip A.; Einloth, M; Butler, K; Eddy, J; Marr, J; Falloon, J; et al.
Pediatric Branch, National Cancer Institute, Bethesda, MD, USA

Objective: An agent that inhibits HIV replication without bone marrow suppression would be an important addition to the antiretroviral armamentarium. ddC, a dideoxynucleoside, like AZT, inhibits reverse transcriptase and is a chain terminator, but without apparent myelosuppression. In adults, ddC resulted in decreased P24 antigen and increases in CD4 counts but caused mouth sores, a rash, and at higher doses and longer courses, a painful peripheral neuropathy. The question is whether short courses of ddC could provide safe antiretroviral activity in children and whether it could be used with AZT.
Methods: In a Phase I study, we evaluated 4 dose levels of ddC: 0.015, 0.02, 0.03 and 0.04 mg/kg, orally, q6h, in children between 6 mos - 13 yrs old with CDC P2 HIV infection. At each dose level, ddC was given for 8 consecutive wks and then stopped. After a 30 d wash-out, a schedule of ddC (0.02 mg/kg/q6h) for 1 wk was followed by 3 wks of AZT (180 mg/m^2/q6h), with this alternating schedule then repeating thereafter. The goal was to maintain uninterrupted antiretroviral therapy while sparing AZT-related myelosuppression and ddC-related neuropathy.
Results: From 4/88-12/89, 15 children, ranging in age from 6 mos to 12 years were enrolled. 13/15 pts had not had any prior antiretroviral therapy, while 2 pts had received and benefited from AZT, but had developed dose-limiting neutropenia. During the 8 wks of ddC alone, no neutropenia or anemia was observed and 7/9 pts whose P24 antigen was elevated prior to ddC had decreases in P24 levels and 9/15 had increases in CD4 numbers. Age-appropriate psychometric testing was performed prior to ddC and at 8 wks. 3 pts with clinical encephalopathy prior to therapy showed improved affect and activity on ddC but this was not accompanied by increments in IQ scores over baseline. At the 0.04 mg/kg level, 3/6 pts developed a rash and 1 pt, at week 7 of ddC, complained of painful hands and feet, associated with mild swelling, but unaccompanied by changes in nerve conduction compared to pre-ddC testing and which resolved within 3 days. 7/15 pts developed mild mouth sores. After completing 8 wks of ddC, and the 30 day wash-out, pts began the alternating ddC/AZT schedule. Eleven pts are on this regimen and tolerating it well to date.
Conclusions: ddC has antiretroviral activity in children and appears safe for short intervals. Longer courses of ddC at lower dose levels, and schedules integrating ddC into combination regimens, deserve to be explored.

T.B.P.248 THE EFFECTS OF ENCEPHALOPATHY AND AZT TREATMENT ON THE SOCIAL AND EMOTIONAL BEHAVIOR OF PEDIATRIC AIDS PATIENTS.

Moss, Howard, Wolters, P, Eddy, J, Weiner, L, Pizzo, P, Brouwers, P. Pediatric Branch, National Cancer Institute, NIH, Bethesda, MD USA.

Estimates are that encephalopathy occurs in as many as 80% of pediatric AIDS patients. Evidence of improved CNS functions appears to be a sensitive indicator of the efficacy of pharmacological treatment. Therefore, it is important to further develop objective and systematic methods for monitoring behaviors reflective of encephalopathy. One such class of behaviors observed among pediatric AIDS patients, that has not been systematically studied, involves the impaired expression of appropriate emotional and social behaviors (e.g., flat affect, severely diminished inter-personal responsiveness, etc.). In order to explicate and quantify these behavioral manifestations of encephalopathy, a rating procedure was devised for describing the social and emotional behavior patterns of this patient population.

Since the behaviors observed in these children simulate well known psychiatric disorders, an item pool was derived from various behavioral disorders listed in the DSM-III. Staff members and parents rated 29 pediatric AIDS patients (approximate mean age of 5 years, 6 months) at baseline and again after 6 months of AZT treatment on 49 behavioral items using a Q sort format. Item analysis and factor analysis resulted in 5 robust scales. 1) autism, 2) depression, 3) hyperactivity and attentional problems, 4) irritability, 5) adaptive behavior. The mean inter-rater reliability for these scales was satisfactory.

Patients who were classified clinically as encephalopathic were rated before treatment as significantly more autistic, depressed and less adaptive than a group of non-encephalopathic patients. These differences generally disappeared after 6 months of treatment, leading to a statistically significant decrease in autistic and depressed behavior and an increase in adaptive behavior after 6 months of AZT treatment for the encephalopathic patients. All of the above findings were statistically significant for both staff members and parents with the magnitude of the findings being greater for staff members. There were a number of statistically significant correlations between the scores on the scales and concurrent hematological, immunological, and behavioral measures on these patients, particularly for the baseline assessments. These correlations help confirm the validity of the rating scales.

T.B.P.249 ELEVATED HEPATIC TRANSAMINASES ARE NOT ASSOCIATED WITH INCREASED ZIDOVUDINE TOXICITY IN CHILDREN WITH CONGENITALLY ACQUIRED HIV-1 INFECTION

Martin, Steven R.; LeMay, MD*; McIntosh, K and Winter HS.
Children's Hospital, Harvard University, Boston, MA, USA; *Boston City Hospital, Boston University, Boston, MA, USA.

Zidovudine(AZT) has been implicated as the cause of acute hepatitis in some adults with HIV-1 infection. In addition, hepatic dysfunction may potentiate AZT bone-marrow toxicity by altering the metabolism of the drug. Children with elevated transaminases [5-10 x normal (nl)] may be excluded from clinical trials with AZT. We followed 9 children (5 females, 4 males, mean age 33 months) with congenitally acquired HIV-1 infection for evidence of liver dysfunction during therapy (180mg/m^2 of AZT po qid).

	AT ENTRY (# of Pts.)				AT FOLLOW-UP (# of Pts.)			
	nl	1-3x nl	3-5x nl	>5x nl	nl	1-3x nl	3-5x nl	>5x nl
Bili	8	0	0	1	9	0	0	0
AST	0	3	2	4	0	5	4	0
ALT	2	4	1	2	2	6	1	0

At follow-up (mean of 14.6 weeks,range 4-32), all patients had improvement or no change in transaminases. Two patients with markedly elevated levels (AST 10-18x nl; ALT 5-18x nl) improved during therapy. Hepatic dysfunction was not associated with AZT bone-marrow toxicity. We conclude that long-term AZT therapy does not appear to cause significant hepatic dysfunction in children. Children with moderately elevated hepatic transaminases may not be subject to increased AZT toxicity.

T.B.P.250 LONG-TERM TREATMENT OF SYMPTOMATIC HIV-INFECTION IN CHILDREN WITH ZIDOVUDINE

Vocks, Mechthild(1), Wintergerst, U.(2); Sauer, S.(3); Kreuz, W.(4); Wahn, V.(3); Rosendahl, C.(2); Koch, S.(1); Haas, S.(4); Debatin, K.M.(5); Kynast, I.(4); Grosch-Wörner, I.(1), Belohradsky, B.H.(2); Ehrenkel, S.(4).
Dept. of Pediatrics, Univ. (1)Berlin, (2)München, (3)Düsseldorf, (4)Frankfurt, (5)Heidelberg, FRG.

Objektive. To evaluate clinical, immunological and virological effects of long-term therapy in children with zidovudine (ZDV).

Methods. 24 patients (pts) with Aids ranging in age from 1-20 years have been treated with ZDV orally in a dosage of 3.5 mg/kg (12 pts) every 6 hours for meanly 44 weeks (4 pts 5 mg/kg; 2 pts 7 mg/kg). 12 pts were HIV-infected perinatally (1-8 yrs), 2 by tranfusion (both 5 yrs), 10 by factor replacement for hemophilia (10 pts, 10-20 yrs).

Results. 20 children demonstrated clinical improvement (7 pts temporary) in the first wks of therapy for unspecific symptoms (CDC class P2A). Mild or transient improvement of neurological symptoms (P2B) occured in 7 of 8 children. Lymphoid interstitial pneumonia (P2C) in 5 children did not change, except one with concomittant steroid therapy. Frequency of bacterial infections (P2D2) have decreased in 4 of 6 pts, opportunistic infections (10 pts) recurred in 3 pts only. In opposite, Herpes infections (P2D3) (4 pts) did not change. 4 children died after 6-30 wks of ZDV treatment from different causes: 2 gastrointestinal bleeding, 1 cardiomyopathy and 1 severe encephalopathy.
CD 4 cell number rose transiently in 12 of 17 pts but decreased to pretreatment numbers after 20-28 wks. Lymphocytic mitogen stimulation improved only in a few cases transiently. HI-Virus has been cultured in 8 of 9 pts under ZDV therapy, while in 3 of 6 pts HIV-p24 Antigen no longer could be demonstrated. Nausea, muscle pain and restlessness appeared as adverse effects in 6 pts, while anemia and neutopenia occured each in 2 pts and both in 4 pts.

Conclusion. Though immunological and virological improvement in children treated with ZDV has been transient or mild, clinical symptoms remained clearly improved for a longer time.

T.B.P.251 CHORIORETINITIS RESPONDING TO AZT THERAPY IN AN INFANT WITH AIDS

Jonckheer, Tijl*, Pierre, C.**, de Seiljs, A.**, Moens, E.**, Taelman, H.*, Piot, P.*
* Institute of Tropical Medicine, Antwerp; ** Algemeen Kinderziekenhuis Antwerp, Belgium

Introduction: Cytomegalovirus (CMV) chorioretinitis is exceptionally reported in children with AIDS (2 cases mentioned). In adults CMV chorioretinitis is known to respond only to Gancyclovir or Foscarnet therapy.
Case report: A six months old boy of African origin born to a known HIV seropositive mother was classified P2 ABCF. A routine fundoscopy of the left eye revealed a blurred optic disc in the right eye with hyperaemia, venous dilatation at the arcade, flame-shaped peripapillary bleedings and a large white patch extending from the optic disc to the macula along the superior vascular arcade. At the same time CMV was isolated from the urine. The right eye was normal. AZT was started at a dose of 3.5 mg/kg every 6 hours and high-dose (350 mg/kg) Sandoglobulin was given every month. After 4 weeks fundus examination under general anesthesia revealed nearly total cicatrisation of the lesion in the left eye. After 3 months follow-up no recurrence was observed. At 7 months the infant developed presumed PCP. Laboratory data are given in the table.

Table:	p24 AB ratio	p24 AG ratio	HIV culture	PCR	CMV urine
4 months	1.2	58.4	ND	ND	-
6 months	-	ND	+	ND	+
10 months	2.0	-	+	+	-

Conclusion: This case report suggests that AZT and high dose gammaglobuline should be tried first in HIV infected infants with chorioretinitis probably caused by CMV before highly toxic drugs like Gancyclovir or Foscarnet are used.

T.B.P.252

AZT THERAPY IN HIV INFECTED CHILDREN

A. Terragna*, Andrea De Maria*, B. Ciravegna*, A. Loy#, F. Forni**, A. Ferrazin*;

* 1 Cl Mal Infettive Istituto G. Gaslini Genova; **Ospedale Galliera Genova, ITALY.

12 children (6 males, 6 females) aged 4 months to 12 years, with HIV infection in class P1 (1 case) or P2 (11 cases) (CDC 1987) were treated with zidovudine (20 to 28 mg/kg/die) every six hours for a mean of six months (range 2-6 months). Out of the study patient 12/12 were HIVp24Ag positive, 7/12 virus culture positive, 5/6 HIV specific IVAP (In Vitro Antibodies Production) positive. During AZT treatment a decrease, or an erratic negativization, of HIVp24Ag was observed; however, persistently negative values of HIVAg were never achieved. We didn't observe any increase in CD4+ lymphocyte count.

We did observe an improvement of general clinical condition with body weight gain (8/12); reduction of volume of lymph nodes (5/12), liver and spleen(4/12) decrease of bacterial and opportunistic infection episodes.

During treatment 2 children had nausea and vomiting and we had transiently to reduce the dosage.

We observed toxicity in 7/12 children. Toxic effect consisted in: i)increased ALT and AST serum levels (in only 2 cases we had to reduce the dosage) ii)anemia (3 patients required a blood transfusion) iii) leucopenia: in two children the PMN count fell below 1000/mmc and we had to reduce the dosage.

T.B.P.253

Zidovudine Treatment in Adolescent Hemophiliac Children with HIV Infection.

Alan P. Knutsen, J.D. Bouhasin, K. Gioia, K.B. Mueller. St. Louis University Medical Center, St. Louis, MO, USA.

Nine hemophilia children with HIV infection, mean age of 13.8-years-old (range 7.6 to 18.1 years), were treated with zidovudine (azidothymidine; AZT), dose 115 ± 14 mg/M^2/dose four times daily orally for 9.9 ± 3.6 months. Three children had acquired immunodeficiency syndrome (AIDS), 1 had AIDS-related complex (ARC), and 5 were asymptomatic. The patients' were known to be HIV infected for 3.7 years (range 1.4 to 5.7 years) prior to starting AZT. Prior to initiation of AZT, mean CD4 cells were 128 cells/mm^3, and after starting AZT were 432 cells/mm^3 at 3 months, 249 cells/mm^3 at 6 months, and 320 cells/mm^3 at 9 months, with 7 patients having increased CD4 cells >200 cells/mm3. However, in vitro lymphoproliferative responses to PHA, pokeweed mitogen, Candida albicans, and tetanus toxoid stimulations did not significantly improve after AZT therapy. Side effects related to AZT therapy were predominantly elevated ALT in 4 patients and neutropenia in 2 patients. These side effects responded to temporary cessation or dose reduction with the exception of 1 patient in whom AZT was discontinued due to severe neutropenia even at reduced doses.

In summary, AZT therapy was generally well tolerated and resulted in increased CD4 cell numbers though not T-cell function in 9 adolescent hemophiliac children treated over 6 to 12 months.

T.B.P.254

DISEASE PROGRESSION AND EFFECT OF ZIDOVUDINE (AZT) IN PEDIATRIC AIDS.

Gupta Anil, Ravipati M, Slade H, Lecambruno C, Marecki M, Pahwa S. Dept. of Pediatrics, North Shore University Hospital, Cornell University Medical College, Manhasset, NY., U.S.A.

Objective: To evaluate infants and children with presumed or established HIV infection and influence of AZT treatment.

Methods: 46 cases, age range 1 mo. to 8 years at presentation, of whom 32 had P1/P2 disease and 14 were in the P0 category were evaluated over a 4 year period. AZT, 360-720mg/m^2 was administered orally to 11 patients in P2 class (with CD4 and T cell counts <400/cmm) for periods of 0.5 to 13 mo.

Results: Of 14 P0 cases, definite HIV transmission occurred in 3 (23%). Asymptomatic infected and uninfected cases <6 mo. were indistinguishable by immunologic testing. 14 of 31 cases in P2 class have died, mainly with OI, at ages 3 mo. to 10 yrs. Progressive decline in CD4+ T cells and in T cell functions was seen in all P2 cases even without obvious evidence of disease progression. At time of death, CD4+ T cell depletion was most striking, as was the occurance of HIV antigenemia. Patients treated with AZT had increased appetite, sense of well being and minimal side effects (eosinophilia in 1 case). Demonstrable benefit was noted in 2 of 3 cases with thrombocytopenia refractory to conventional therapy. Although increase in CD4+ T cells was often transient, their progressive attrition appeared to be halted. In vitro HIV antibody secretion by patient lymphocytes became positive after initiating AZT in 2 previously negative cases.

Conclusion: In the natural course of HIV disease, immunologic attrition precedes clinical disease progression. In children, AZT has subtle clinical benefits, is minimally toxic and appears to slow down immunologic attrition.

T.B.P.255

OUR EXPERIENCE IN TREATMENT WITH ZIDOVUDINE IN CHILDREN.

MªJosé Mellado,MJ.Cilleruelo,M.García,J.Villota,ML.Pérez, P.M. Fontelos.Instituto Carlos III.Serv.Pediatria.Madrid. SPAIN.

In October 87,we began a prospective study to evaluate the effectiveness of Zidovudine(ZDV)in the treatment of children suffering from AIDS.Selection parameters were:1)Children with viraemia or HIV antibodies and sympthomatic infection according to class P$_2$ of CDC for pediatric AIDS.2)To be older than 3 months and less than 12 years old.3)Hemoglobin>10gr/l.Leukocytes>2.000.Neutrophils>1000 and platelests>50.000.4)Creatinine<1.6.ALT<150U/l.No jaundice.5)Guardian's consent and authorization from clinical assays committee of the hospital.We present 8 children,5males and 3 females,whose ages range from 3½months to 11 years; two of them were infected through blood transfusions and the other 6 from their mothers who are DAVP and infected with HIV.We use the IV commercial form of ZDV and it's administered orally in a dosage of 28mg/k/d.We analyse the clinical, hematological and immunological responses to treatment.Virology tests were performed by ELISA, IFI, W. blot and capture Ag methods.

RESULTS:All cases have improved clinically,showing at the beginning a better appetite and nutritional status,and a decrease in number of recurrente infectious diseases.The tolerance has been excellent.We have observed a moderate decrease of hemoglobin,macrocytosis with normal values of vitamin B$_{12}$ and mild neutropenias.It hasn't been necessary in any case to reduce or withdraw medication.We have observed a decrease of values immunoglobulins in 3 patients.Two of the four children who presented a positive HIV Ag in serum showed a decrease in it's value during treatment.

CONCLUSIONS:1)All patients showed an excellent tolerance to ZDV without any hematological toxicity.2)We have noticed a decrease of the amounts of immunoglobulins and of P$_{24}$ Antigen in serum during treatment.3)Improvement in the quality of life.4)It's reasonable to supoose than this drug will be more effective in the less affected children,so we suggest the possible treatment in more precocicus stages of the disease.

T.B.P.256

SELENIUM DEFICIENCY AND CARDIOMYOPATHY IN MALNOURISHED PEDIATRIC AIDS PATIENTS

Kavanaugh-McHugh, A; Rowe, S; Benjamin, Y; Hutton, N; Modlin, J; Ruff, Andrea; et al
The Johns Hopkins Hospital, Baltimore, MD, U.S.A.

Objective. To examine the relationship between selenium deficiency and cardiomyopathy in pediatric AIDS patients.

Methods. Echocardiograms and serum selenium values were obtained on 9 pediatric patients undergoing therapy with azidothymidine for symptomatic HIV disease. Cardiomyopathy was defined as ejection fraction less than 60% and/or left ventricular diastolic dimension greater than the 95th percentile for surface area. Patients were assessed for malnutrition using the Waterlow classification.

Results. Five of the 9 patients were selenium deficient (<80mcg/L). All 5 had protein calorie malnutrition with wasting and/or stunting by the Waterlow classification. Four of the 5 had evidence of cardiomyopathy with decreased ejection fraction and/or left ventricular dilatation. One of these five patients has had normalization of his serum selenium on supplementation with improvement in ejection fraction.

The four patients with normal serum selenium values had no evidence of malnutrition by the Waterlow classification. Two of these patients had evidence of cardiomyopathy by echocardiography.

Conclusions. Selenium deficiency is common in malnourished pediatric AIDS patients and may have a role in the pathogenesis of cardiomyopathy in this population. Additional studies are underway to determine the effect of selenium supplementation on cardiac function in these patients.

T.B.P.257

CLINICAL AND IMMUNOLOGICAL COURSE OF HIV-INFECTION IN HEMOPHILIAC AND PERINATALLY INFECTED CHILDREN PROPHYLACTICALLY TREATED WITH IMMUNOGLOBULINES CONTAINING HIGH TITERS OF ANTI-CMV, ANTI-EBV AND ANTI-HIV AND TIMING OF AZIDOTHYMIDINE MEDICATION.

A PROSPECTIVE LONGITUDINAL STUDY OF 61 CHILDREN

W. Kreuz, [illegible]
Klinikum der J.W. Goethe-Universität, *Paul-Ehrlich-Institut, **Georg Speyer Haus, Frankfurt am Main, FRG

In our clinic we care for 61 children consisting of 10 HIV-infected hemophiliacs or von Willebrand patients (up to 19 years) and 51 born to HIV-positive mothers (up to 5,5 years). 34 children are classified as P 1 and P2, 6 are classified as P 0 according to CDC-criteria, 21 were initially P 0 and considered not to be infected at the age of 15 months. Since the end of 1986 we conduct a prospective prophylactic intravenous immunoglobuline therapy (IVIGG), using preparations with high titers of anti-CMV, anti-EBV (Cytotect®; neutralizing Anti-CMV-titer: 50 U/ml). In case of continuous loss of HIV-antibodies (Western-Blot) we use IGG-preparations containing high titers of HIV-antibodies (all preparations are virus-inactivated by means of β-propiolactone/UV). During clinically highly symptomatic periods patients receive 400 mg/kg b.w. once or twice a week, after improvement 200 mg /kg b.w. once a week or every other week resp. We start IVIGG when clinical signs and symptoms of B-cell dysfunction e.g. increased incidence of bacterial infections, poor in vitro PWM- or SAC-lymphocyte-stimulation, low antibody response to diphtheria/tetanus vaccines and hypergammaglobulinemia are present. Children with unspecific symptoms like persistent diarrhea, parotitis, fever and growth retardation and children with reduced T-cell-function presenting as persistent oral candidiasis and/or frequent herpes infections are given IVIGG prophylactically in order to support their immune system by prevention of various viral infections and characteristic diseases of childhood. Depending on that we thus expect to reduce HIV-replication. Furthermore we add oral AZT (Retrovir®, 7-14 mg/kg b.w./die q.i.d.) in cases of onset of neurological symptoms, HIV-encephalopathy, opportunistic infections or rapid immunological deterioration. In patients with severe HIV-associated or AZT-induced neutropenia the usability of lymphokine GM-CSF is under investigation. In cases of severe CD4-lymphocyte deficiency (< 100 CD4-cells/mm^3) prophylaxis with co-trimoxazol (5 mg/kg b.w./d) or pentamidine-isethionate-inhalations (4 mg/kg b.w.) every other week successfully prevented pneumocystis-carinii-pneumonia. Until the conclusion of this study we have not observed symptoms classified as P 2 E (HIV-associated tumors). During 30 months of therapy we observed only two cases of opportunistic infections (children without pneumocystis carinii pneumonia prophylaxis) and only one case of lymphoid interstitial pneumonia. Except this case we did not see any EBV- or CMV-related infections including CMV-retinopathy and oral hair leukoplakia during this observation period. Neurological symptoms occurred in two cases and showed satisfactory remission under AZT-treatment. 8 of 19 treated children with IVIGG had no deterioration of CDC-classification in spite of declining immunological parameters. One hemophiliac and one intrauterine infected child died in a state of totally destroyed immunological function (for months no detectable absolute CD4-lymphocyte count and no B-cell function). 9 children showed a considerable clinical improvement. One of them who has been classified as full blown AIDS for 4 years is currently still without clinical symptoms despite zero CD4-lymphocytes and lacking in vitro-B-cell function since 15 month.

T.B.P.258

EXPERIENCE WITH CENTRAL VENOUS CATHETERS IN PEDIATRIC AIDS

Fullerman, Donna, Connor, E., Boland, M., Oleske, J., Children's Hospital of NJ & UMD-NJ Medical School, Newark, New Jersey USA

Objective: Children with AIDS are at high risk for infection and malnutrition, frequently requiring prolonged venous access for antibiotics and nutritional support. We undertook this study to determine the course and complication rate of central venous catheters (Broviacs) when used in a pediatric AIDS population.

Methods: Retrospective chart review of 200 HIV infected children in Newark, NJ (1982-88).

Results: 23/26 children who received Broviacs had charts available for review and received 35 Broviacs. All 23 had CDC defined AIDS (85% with CD4 <400). Mean age at insertion was 28 mo. (10 wk - 11 yr). Mean duration of placement was 115 d (20-400) for a cumulative total of 4040 days. In 23/35 courses, children were able to go home, with family training and nursing support, for a mean duration of 72 d. There were no catheter related deaths. Nine Broviacs were removed for mechanical problems. Of all febrile episodes (55) evaluated during catheter placement, 21 documented catheter related infections occurred. Ten bacteremic episodes were successfully treated with Broviacs remaining (Organisms: 6 staph, 3 strep, 3 gram neg). Eight catheters were removed because of inability to clear the infection (Organisms: 3 candida, 3 staph, 3 strep, 1 gram neg). Of 3 local infections, one tunnel infection was successfully treated and 2 catheters were removed for exit site infections with pseudomonas. These 18 bacteremic episodes represent 4.5/1000 days of catheter use.

Conclusion: Our infection rate with Broviacs in children with AIDS (4.5/1000) compares favorably with previously documented infection rates in pediatric oncology patients (.5-7.5/1000). Broviacs can be safely used at home for outpatient antibiotics and nutritional therapy in this high risk population.

T.B.P.259

NEOPLASTIC DISEASES IN CHILDREN WITH AIDS: V. V. Joshi, E. M. Connor, F. DiCarlo, L. G. Epstein, J. M. Oleske. Departments of Clinical Pathology and Pediatrics, East Carolina University School of Medicine, Greenville, NC, USA and Children's Hospital of New Jersey, New Jersey Medical School, Newark, NJ, USA

Objective. To describe the incidence and types of neoplastic diseases (ND) in children with AIDS.

Methods. Biopsy (35 cases) and/or autopsy (18 cases) material from 102 HIV infected children.

Results. Seven cases showed ND. The risk factor in five of the cases was parental IV drug use. In 2 cases HIV was acquired via transfusion of blood or blood products. In 2 cases, ND was the first major evidence of HIV infection, in 3 it was part of a complicated course and in 2 it was found at autopsy. Following types of ND were present: 1) polyclonal polymorphic B cell lymphoproliferative disorder (PBLD) characterized by involvement of lymph nodes, spleen, kidneys, liver and particularly of lungs (brain was not involved) seen in 2 cases represented progression of pulmonary lymphoid hyperplasia/lymphoid interstitial pneumonitis. PBLD is considered as intermediate in biologic behavior between benign and malignant lymphoproliferations; 2) malignant lymphoma involving only the brain in 3 cases; 3) leiomyosarcomatosis of gastrointestinal tract (40 primary tumors extending from stomach to colon), with metastasis to lymph nodes, lungs and brain in one case; 4) Kaposi's sarcoma of skin of face, arms and groins in a child with transfusion acquired HIV infection.

Conclusion. HIV associated ND may be more common than previously recognized and may occur at any point in the symptomatic course.

T.B.P.260

SAFETY AND EFFICACY OF CENTRAL VENOUS CATHETERS IN PEDIATRIC AIDS PATIENTS

Gleason-Morgan, Deborah; Church, J; Bagnall H; Atkinson J.
Childrens Hospital of Los Angeles & University of Southern California School of Medicine, Los Angeles, California, U.S.A.

Objective. To determine the safety and efficacy of central venous catheters (CVCs) in pediatric AIDS patients(pts).

Method. A retrospective chart review of children with CDC-defined AIDS (P2D) who had CVCs placed due to inadequate venous access.

Results. The medical records of 11 pts(7 male,4 female), ages 3 mos to 12½ yrs (mean≥47 mos) were reviewed. Risk factors included blood transfusions in 7 and perinatal exposure in 4 pts. Mean absolute granulocyte count(AGC) at the time of CVC placement was $3062/mm^3$, with 3 pts having an AGC of $< 1000/mm^3$. Mean CD4+ cell #'s were $243/mm^3$, with 10 pts having CD4+ #s $< 500/mm^3$. No morbidity or mortality was associated with the CVC operative procedures. Thirteen CVCs(9 double lumen, 1 single, 3 totally implanted) were placed for a total of 1812 CVC days(mean=139 days/CVC). The 13 CVCs were used for the following: parenteral nutrition-12; IVIG-11; blood products-12; other medicines-11; blood draws-11. Four episodes of CVC-related sepsis(in 3 pts) occured(.22 infections/100 CVC days) resulting in removal of 3 CVCs. Klebsiella, Enterobacter species and S. Epidermidis were isolated from individual CVCs. Three CVC occulsions(radiographically confirmed) occurred, 2 of which spontaneously resolved, 1 which required operative CVC revision.

Conclusion. The rate and types of CVC infection in children with profound HIV related CD4+ cell deficiency approximates that seen in pediatric oncology pts. CVCs proved valuable in pts requiring multiple therapeutic interventions.

T.B.P.261

HIV INFECTION (HIV) IN PATIENTS (PTS) TREATED FOR LEUKEMIA OR SOLID TUMOR, A PEDIATRIC ONCOLOGY GROUP (POG) STUDY

Baruchel, Sylvain*; Clavel, L.**; Toledano, S.***
*McGill University,Montreal,Quebec,Canada,**University of Puerto Rico,San Juan,Puerto Rico,USA,***University of Miami,Miami,Florida,USA

Objective and Methods. A questionnaire was sent to POG institutions to enquire about (a) the number of pts infected by HIV among children treated for leukemia or solid tumors; (b) the impact of chemotherapy on the natural history of HIV; (c) the interaction between HIV and cancer; (d) and institutional attitudes regarding HIV testing and confidentiality.

Results. Ten of 74 responding institutions reported a total of 19 HIV infected pts (14 leukemias, 5 solid tumors; 12 boys, 7 girls; ages 10 mos-20 yrs). Thirteen pts were diagnosed off-therapy, 6 pts on therapy. Sixteen pts acquired HIV post-transfusion. Three pts with congenital AIDS developed B-cell leukemia before the age of two. A correlation exists between number of cases by institution and geographic HIV seroprevalence. The median interval between transfusion and diagnosis of HIV was 29 mos (range 5 wks-6 yrs); between transfusion and death was 30 mos (range 2 mos-8 yrs). 18/19 HIV+ pts developed AIDS, one remains asymptomatic. 12/19 have died (6 CR, 6 PD). Two pts are being treated with Ig or AZT.

Conclusion. (1) No true seroprevalence was available; (2) A correlation existed between HIV+, geographic area and number of transfusions; (3) HIV status appeared not to affect tolerance of chemotherapy; (4) the natural history was different from hemophiliacs but similar to other transfused pts; (5) Testing with consent form, counselling, follow-up and therapeutic guidelines is recommended for pts transfused in high seroprevalence areas.

T.B.P.262

VERY LATE ONSET OF GROUP B STREPTOCOCCAL SEPSIS IN INFANTS WITH HIV INFECTION.

Di John, David*; Johnson, JP**; Lawrence, R*; Schieken LS**; Rennels, MB**.
*New York University Medical Center-Bellevue Hospital Center, New York, NY, USA and **University of Maryland, School of Medicine, Baltimore, MD, USA.

Objective. To describe characteristics of Group B streptococcal (GBS) disease in HIV infected children.

Methods. GBS disease was identified in 3/200 (1.5%) of HIV infected children diagnosed at the University of Maryland and NYU Medical Center. Charts were reviewed to describe clinical features, course, and outcome of GBS disease.

Results. GBS patients were 3.5, 5 and 5 months of age respectively. Each had evidence of HIV infection as well as immunologic dysfunction including low T-cell counts and poor mitogen responses. All had fever > 102F, elevated WBC's ranging from 10,000 - 20,000, and marked left shift. Two presented as meningitis with bulging fontanel, irritability, and seizures. Both had CSF pleocytosis and + CSF cultures for GBS. One presented with tachypnea, rales, apnea, and radiographic evidence of bibasilar pneumonia. The course of each patient was unusually complicated. All 3 responded to IV beta-lactams.

Conclusions. GBS disease (meningitis and pneumonia) occurred beyond the usual age of onset in these HIV infected children. Despite immunosuppression and severe GBS disease these patients mounted PMN cell responses and improved with beta-lactam antibiotics.

T.B.P.263

DIARRHEA AND ITS CONSEQUENCES IN HIV-INFECTED CHILDREN.

Kotloff, Karen; Johnson J.P.; Nair P.; Losonsky G.A.; Young A.; Morris J.G.
University of Maryland School of Medicine, Baltimore, Maryland, U.S.A.

Objective: To determine the incidence, etiology, and sequelae of diarrhea in children with symptomatic HIV infection.

Methods: Children with AIDS and ARC (n=16) were prospectively enrolled and serially evaluated. When a physician visit was made for diarrhea, a whole stool or rectal swab was examined for bacterial enteropathogens, protozoa (whole stool only), mycobacteria, viruses, and *Clostridium difficile* toxin.

Results: During the first 11 months of study, the incidence of diarrhea was 0.13 episodes per child-month, which is 2.6 times the incidence we have observed in seronegative children born to HIV-infected or high risk women (mean age 7.3 ± 5.7 mo.), and 7.2 times the incidence in inner city Baltimore children (mean age 7.9 ± 6.2 months). Four cases were hospitalized because of diarrhea, and one case with salmonellosis died. Two cases had recurrent (≥3 episodes/year) and one had persistent (≥14 days) diarrhea. Wasting (weight for height < 5th percentile) was seen in 4 children.

No. child-months after enrollment	143
Mean age at enrollment in mo.s	17.5 ± 10.7
No. of diarrheal episodes (DE)	18
No. patients (%) with DE	11 (61)
No. DE/child-mo. after enrollment	0.13
No. (%) DE with enteropathogen	7 (39)

*Includes 1 rotavirus, 1 *Salmonella*, 2 *Shigella*, 1 *Campylobacter*, 1 *Giardia*, and 1 *C. difficile* toxin.

Conclusion: Diarrhea is a major cause of morbidity in HIV-infected children and occurs at a rate that is 2-7 times higher than the reported incidence in uninfected children. A potentially treatable infectious etiology can be detected in almost 1/3 of all episodes.

T.B.P.264 BURKITT LYMPHOMA IN AN HIV-INFECTED CHILD

D. Caselli, M. Aricò, A Deicas*, G. Michelone*, A. Maccabruni, P. Lanzarini*

Depts. Pediatrics, *Infectious Diseases, University of Pavia, Italy

HIV infection in children is infrequently complicated with malignacies: Kaposi sarcoma (less than 5%), a few cases of malignant brain lymphoma, one case of Burkitt lymphoma (BL) were reported. We describe BL in a 3-year-old white female, born to drug abuser seropositive mother, admitted because of fever, anorexia, increasing abdominal girth. HIV seropositivity, failure to thrive, enlanged lymphonodes, liver and spleen where evident when 3-month-old. Persistent interstitial pneumonia still the age of 18 months. During the next years policlonal hypergammaglobulinemia, reversed CD4/CD8 ratio and HIV seropositivity persisted (P2ACD)-1 according to CDC). On admission she was febrile, poorly nourished with dyspnea and generalized lymphadenopathy; her abdomen was protuberant and tender, liver margin at 11 cm, spleen 9 cm. WBC 13.700/ul (N 45%,L 50%,M 3%,E 2%), ESR 18 mm/hr, IgG 3210 mg/dl, IgA 218 mg/dl, IgM 282 mg/dl, CD3+ 78%, CD4+ 28%, CD8+ 54%. Serum was positive for HIV antibodies in ELISA and W. blot (p17-24-31-55-6651, gp 120-210). CMV was isolated from body fluids. Narcosis for brain scan (normal) caused severe hypertermia. US scanning: numerous massively enlarged porta hepatis (4.9 cm) and splenic lymphnodes. Examination of biopsy specimens of skin nodules changes consistent with BL. Combination chemotherapy (VCR, CYC, PDN, iv+it MIX) was started. Dramatic clinical improvement was evident within two week: abdominal circumference decreased by 11 cm and US scan showed disappearance of abdominal nodes. In case of massive abdominal distension in HIV infected children, most if some years after the onset of signs of illness, opportunistic lymphoproliferative neoplasia should be ruled out. If detected, it can be temptatively treated with specific chemotherapy with some advantage.

T.B.P.265 CHRONIC MUCOCUTANEOUS CANDIDIASIS IN PEDIATRIC AIDS

Iosub, Silvia; Bamji, M.; Stone, R.K.; Gromisch, D.S.; Wasserman, E.
New York Medical College, New York, USA

Objective. To compare the indidence of persistent mucocutaneous candidiasis in patients diagnosed as AIDS in the first year of life (group I) vs those diagnosed later (group II).
Methods. The study was performed at two public hospitals in New York City on sixty two patients with perinatal HIV infection admitted from 1984-1988 and followed for 1-50 months (mean 18 mo). All mothers except three were intravenous drug abusers. The majority of patients in group (G) I became symptomatic in the first six months of life. The G consisted of 42 patients, 14 blacks (b) and 28 Puerto Ricans (PR) 21 males (m) and 21 females (f). G II comprised 20 patients, 13 b and 7 PR, 12 m and 8 f, ranging in age from 12.5 months to 72 months (mean 17 mo).
Results. Chronic mucocutaneous candidiasis was significantly more frequent in G I vs GII: 50% vs 10%, P=0.006. There were no significant race or sex differences between groups, but in GI b f were more often afflicted than PR f (60% vs 31%). Also in GI candidiasis was the sole initial manifestation in 5 patients (12%) and 3 of these (60%) died by four months of age. In GII candidiasis was found only in PR, with no significant sex differences (25% in m vs 33% in f).
Conclusion. In the very young infant with perinatal HIV infection chronic mucocutaneous candidiasis may predict early and severe morbidity. Long term follow-up is needed to elucidate its prognostic value in older infants and children.

T.B.P.266 OPPORTUNISTIC INFECTIONS AND MORTALITY IN AN URBAN PEDIATRIC POPULATION INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV)

Hanson, I. Celine; Rosenblatt, H.M. and Shearer, W.T. Baylor College of Medicine and Texas Children's Hospital, Houston, Texas, USA.

Objective. To define opportunistic infections (OI) that were most prevalent and linked with the highest mortality rate in an urban pediatric population.
Methods. 73 pediatric HIV patients followed up to 7 years (mean 2 years) were reviewed for evidence of OI (Centers for Disease Control, stage D-1).
Results. As in the adult population, pneumocystis carinii pneumonia (PCP) was the most frequently reported opportunistic organism with a high mortality rate linked to both a) clinical presentation with acute respiratory failure and b) co-infection with cytomegalovirus (CMV). CMV infection had the highest mortality rate with documented pneumonitis (3/5), hepatitis (1/5) and retinitis (1/5). Bacterial infections were not as common as in other reports.

OI	# of Patients	Mortality	Recurrence
PCP	9	66%	No
CMV	5	100%	No
M. Avium intracellularle	4	25%	No
Salmonella	2	0%	Yes
E. Coli	1	100%	No
Strep. pneumonia	1	0%	Yes
Candida Esophagitis	2	0%	No

Conclusion. The incidence of OI was 25% (18/73) with mortality high for PCP, CMV and gram negative sepsis (averaging 90%). Attention should be focused on early detection and intervention for OI. Protocols defining and standardizing therapeutic approachs to OI in children must be designed and implemented.

T.B.P.267 SPECTRUM OF INFECTIONS IDENTIFIED AT AUTOPSY IN PEDIATRIC AIDS

Ross, Lawrence A.; Wong,V.K.; Gomperts, E.D.; Ricalde, A.L. and Church, J.A. Childrens Hospital of Los Angeles and U.S.C. School of Medicine, Los Angeles, California, U.S.A.

Objective: To identify the spectrum and sites of infection in children dying of AIDS. Method: 33 children with full-blown AIDS have been followed at Childrens Hospital of Los Angeles; 22 have expired; 12 postmortem examinations revealed the following:

ORGANISM	# OF PTS	SOURCE	CLINICAL CORRELATES
P. carinii	7	lungs(L)	pneumonia(P)
Candida Spp.	5	L, pharynx, heart(H), blood(B), kidney, bladder, esophagus	P, thrush, esophagitis endocarditis, disseminated disease(DD)
Cytomegalovirus	5	H, L, pancreas, adrenal glands, thyroid, brain(Br)	P, DD, myocarditis, enterocolitis, encephalitis(E)
M. avium complex	2	B, L	P, sepsis(S)
Adenovirus	1	L, P, Br	DD, P, E
P. aeruginosa	1	B, L	S, P
E. coli	1	B, L, peritoneum	S, P, peritonitis
S. pneumoniae	1	L, meninges	P, meningitis
RSV	1	L	P

Conclusion: Multiple infectious agents may be responsible for a fatal outcome in children with AIDS. This indicates the need for a wide range of improved antimicrobial therapy for these children.

AZT SK/thrombocytopénie et autres traitements
AZT KS/Thrombocytopenia and Other RX

T.B.P.268 HEMATOLOGIC EFFECTS AND OUTCOME OF ZIDOVUDINE (AZT) THERAPY.

Schlech, Walter*; Marrier, G.* and Johnston, B.*
* Dalhousie University Faculty of Medicine, Halifax, Nova Scotia, Canada

Objective. To describe the hematologic effects and outcomes of zidovudine (AZT) therapy in CDC group III and group IV HIV-infected patients (pts).
Methods. 20 AIDS and 14 group IVa and group III (n=34) pts were enrolled in the open trial of AZT and follwed prospectively. Hematologic parameters studied included granulocyte count (GC ct), platelet count (PLT ct), hemoglobin (Hgb), mean corpuscular volume (MC), and lymphocyte (CD4 cts) counts.
Results. Of 34 pts enrolled, 7 are dead, 12 are off Rx., and 14 remain on Rx. Deaths were due to disseminated KS (1), recurrent PCP (2), progressive dementia (2), inanition (1) and lymphoma (1). Disseminated CMV (2), MAI (1) and stage IV lymphoma have developed in 4 pts continuing Rx. Serial CD4 cts demonstrated significant increases in 9/16 pts able to take 1200 mg/day of AZT. Pts. with CD4 cts < 100 cu/mm did not show increases to > 100 cu.mm. Progressive macrocytosis was seen in 31/34 pts. Pts. with starting Hgb < 14 g/dl were more likely to have significant decreases in Hgb on Rx ($p < .05$). GC cts varied but increases were noted when GC cts were low at start. PLT cts remained stable or increased slightly.
Conclusions. Zidovudine causes predictable macrocytosis and unpredictable anemia. GC and PLT counts may improve with suppression of active HIV infection. Opportunistic infections and malignancies continue to develop in patients taking zidovudine.

T.B.P.269 THROMBOCYTOPENIA IN HIV INFECTION

Sacchi Giuseppe*; Zorzi F.**; Benetti M.**; Falchetti M.*; Stellini R.*** and Scalzini A.***.

1**, 2*** Service of Pathology, 1° Div. of Infectious Diseases***, Spedali Civili Brescia, Italy.

Objective: to describe the incidence of thrombocytopenia in HIV positive pts., to assess the bone marrow lesions and the prognostic significance of thrombocytopenia in the AIDS evolution.
Methods: on Dec. 31, 1988, eighty-eight cases of thrombocytopenia were observed within a population of about 1000 HIV positive pts. at the 1° Division of Infectious Diseases Follow-up began about 30 months before with an average 21-month observation. Bone marrow biopsies from 32 thrombocytopenic anti-HIV positive pts. were observed at light and electron microscopy. The 19 group II pts. and the 13 group III pts. (CDC 1986) were initially all free from opportunistic involvement and neoplasms and required no medication. Platelets were less than 100.000/mmc; pts. were all drug-addicts with evidence of HBV infection in 28.
Results: bone marrow (b.m.) specimens revealed an increased number of megakaryocytes in 25 pts. with hypereosinophilia in 26 and plasmacytosis in 15; these lesions represented the main b.m. involvement. No evidence of granulomas or acid fast organisms was found. These data suggest a probable mechanism destroying blood platelets peripherally in the absence of bone marrow underproduction. At the present follow-up only two pts. undergoing a bone marrow biopsy evolved to full-blown AIDS.
Conclusion: 1) 9% of the HIV positive population presents thrombocytopenia as a clinical sign of early bone marrow involvement. 2) The main bone marrow alterations are characterized by an increased number of megakaryocytes with hypereosinophilia and plasmacytosis. 3) Thrombocytopenia has no unfavourable prognostic meaning in the evolution to AIDS.

T.B.P.270 PLATELET PRODUCTION IN HIV INFECTION - EVIDENCE FOR A COMPENSATED THROMBOLYTIC STATE ENHANCED BY AZT

Balles, Penny*, Belzberg, A *°, Chambers, H °, Spruston, B*.
Departments of Medicine*, Nuclear Medicine° and Nursing°, St. Paul's Hospital, and the Canadian Red Cross Blood Transfusion Service, Vancouver, B.C., CANADA.

Thrombocytopenia(↓plt) is common in HIV infection, often due to marrow suppression 2° infection, drugs or infiltration. In the absence of these, some patients have ↓plts. associated with ↑plt.-associated IgG (HIV-ITP). Kinetic studies performed with ^{111}-Indium-labelled plts. in 12 patients with HIV-ITP (mean plt. ct. $49 \pm 32 \times 10^9$/L) revealed significantly shortened survivals (mean 97 ± 31 hr) compared to HIV non-infected controls (n controls) (mean 194 ± 11 hr)($p < .001$). Furthermore, total plt. production in HIV-ITP patients (TPP=Plt. ct.x90%xTotal Blood Vol./plt. surv.x %recov.) was suppressed (mean TPP=95×10^9plt/D) when compared to n controls (mean TPP=209×10^9 plt/D)($p < .001$). Treatment of 7 HIV-ITP patients with AZT at 200 mg q4H resulted in a rise in the plt. ct. which was associated with a slightly prolonged plt. surv.(mean plt.surv.=128 ± 44 hr) and a dramatic rise in TPP (mean TPP= 275×10^9plt/D). To further investigate, plt. kinetics were done in clinically stable non-thrombocytopenic HIV+ controls(n=11) and HIV+ controls on AZT (n=12). Platelet survivals in 63% of patients in both groups were significantly below normal (<2 S.D.), with TPP increased in 4/11 HIV+ controls compared to n controls. In HIV+AZT controls, TPP was significantly increased (mean=330×10^9plt/D, $p < .02$) compared to n controls. These findings suggest that HIV+ individuals with normal plt. cts. may be in a compensated thrombolytic state. AZT appears to have a nonspecific stimulatory effect on platelet production which may be useful in patients with HIV-ITP who have significant suppression of plt. production.

T.B.P.271 EFFECTS OF LONG TERM ZIDOVUDINE ON PLATELET COUNT.

Flegg PJ*, Jones ME*, MacCallum LR*, Williams NP**, Cook MK***, Brettle RP*. *ID Unit; City Hospital, Haematology, **Royal Infirmary and ***Bangour General Hospital, EDINBURGH. UNITED KINGDOM

OBJECTIVE: To assess the long term platelet response of zidovudine following reports of short term beneficial effects in HIV related immune thrombocytopenia (ITP).

METHODS: 38 patients received zidovudine in standard doses with adjustments or stoppage for toxicity for >12 weeks (14 with AIDS and 24 others). 26 patients had normal platelet counts (NP) and 12 were thrombocytopenic (TP) pre-treatment, 5 with presumed HIV- ITP of whom 2 had counts <15 x 10(9)/1.

RESULTS: The median follow-up was 26 (range 12-54) weeks. Mean pre-treatment counts were 240 x 10(9)/1. for NPs and 91 x 10(9)/1. for TPs. Changes in platelet count from this baseline are given below (x10(9)/1.

Weeks Rx	Mean Plats(NP)	Change(NP)	(No.)	Mean Plats(TP)	Change(TP)	(No.)
8	295	+55	(26)	176	+85	(12)
16	238	- 2	(23)	166	+75	(11)
24	206	-34	(20)	139	+48	(8)
32	202	-38	(16)	129	+38	(7)

The fall in platelet count in NPs was significantly associated with the development of severe transfusion dependent anaemia (< 8 gms/dl., 5 patients, p<0.05) but not with risk group, clinical disease stage, occurrence or treatment of opportunistic infections.

CONCLUSION: In thrombocytopenics, zidovudine can produce a sustained platelet rise, and may prove to have a therapeutic role for the treatment of symptomatic HIV ITP.

T.B.P.272 Response to splenectomy for severe HIV-related thrombocytopenia in 10 drug abusers and pathological features of the spleens.

Landonio,Giuseppe; de Cataldo,F.; Gargantini,L.; Nosari,A.M.;Costantini,M.*; Gambacorta M.#Department of Hematology and #Pathology,Niguarda Ca'Granda Hospital,Milan,Italy

Objective:To evaluate the response to splenectomy for severe HIV-related thrombocytopenia in a medium term follow-up and the pathological features of the spleens.

Methods:10 patients (all intravenous drug abusers -IVDAs-) with severe HIV-related thrombocytopenia (PLT <20x10^9/L) who failed to respond to standard steroid therapy and showed continuos significant bleeding, underwent splenectomy (mean follow-up: 7 months prior and 29 after surgery).Relevant data: M:7 F:3; mean age: 27; mean platelet count: 7x10^9/L. All spleens were examined macroscopically immediately after surgery. Multiple sections were stained with a panel of monoclonal antibodies.

Results:

Haemorrhages		Early response (*)	Late response (*)			m CD4 (**)		m CD8 (**)	
pre	post	>100	>100	>50	>25	pre	post	pre	post
10/10	0/10	10/10	4/10	4/10	2/10	0.443	0.338	0.578	1.336

(*) : Plt x 10^9/L . (**) : x 10^9/L .

4 patients had a long lasting remission;the other 6 are in partial remission without bleeding. Two patients progressed from III CDC stage to IVC2, but none evolved to overt AIDS. No significant infection was observed early after splenectomy and during follow-up. The increase of CD8 levels was the only significant variation of the lymphocite subset after splenectomy. The mean weight of spleens was 251 gr.; the only findings wich seem to be peculiar are the "whorne-eaten" aspect of the follicles and the B-cell prevalence in the red pulp.

Conclusions:Splenectomy proved to be effective and riskless, in our experience, in the treatment of severe HIV related TP in IVDAs. The pathological picture of the spleens is essentially that of some degree of congestion with a pooling of platelets, associated with subtle modifications of T and B-cell compartments.

T.B.P.273 HIV-RELATED IMMUNE THROMBOCYTOPENIA : FOLLOW UP AND TREATMENT OF 132 PATIENTS

Eric OKSENHENDLER, M.P. ARCHAMBAULT, JF DELFRAISSY, P. BIERLING, J.PEYNET, M. SELIGMANN - Groupe d'étude des cytopénies liées au HIV - Paris - France

Objective : Longitudinal study of HIV infected patients with thrombocytopenia (platelets$< 50 \times 10^9$/l).

Patients at initial evalulation : 132 patients (IV drug addicts : 56 ; homosexual men : 36, hemophiliacs : 23 ; others : 17). 56% belonged to CDC group II, 30 % to group III and 14 % to group IV, none had AIDS. CD4 cell count was$< 400 \times 10^6$/l in 41/115 (36 %). Serum P24 antigenemia was detectable in 11/75 (15 %).

Treatment : 34 patients received zidovudine (1 000 mg to 1 500 mg/day) for at least 12 weeks. 15 achieved a persistent increase in platelet counts. In most patients, other treatments such as corticosteroids and IV immunoglobulin gave only transient responses. Thus, splenectomy was performed in 38 patients with severe symptomatic thrombocytopenia and resulted in a persistent increase of platelet counts in 33 (87 %).

Follow up : Within a total follow-up of 2 987 months-persons (median : 21 months) from the diagnosis of immune thrombocytopenia, 11 patients have developed AIDS and 11 died. 10 patients were lost for follow up. AIDS-free survival was 90 % at 2 years, 79 % at 4 years and is expected to be 60 % at 5 years.No differences in AIDS-free survival were noted according to risk groups or splenectomy.

T.B.P.274 HIV - ASSOCIATED THROMBOCYTOPENIA (HTP), PLATELET - ASSOCIATED IMMUNOGLOBULIN (PAI) AND ZIDOVUDINE.

V Cárcaba, JA Carton, P Vicente, JA Maradona, F SanRoman, R Llorente, Z Garcia
HOSPITAL UNIVERSITARIO DE OVIEDO. SPAIN

OBJECTIVE. To establish the incidence, permanence and pathogenic role of PAI in HTP treated with Zidovudine, and in non-thrombocytopenic HIV-infected patients.

METHODS. PAI was determined by platelet suspension immunofluorescence test to 25 HIV-infected patients with normal platelet count and 8 HTP (<100 x 10 platelets/L). HTP group received treatment with Zidovudine (200 mg/q4h) during 16.6 ± 14 weeks and PAI was again determined after thrombocytopenia remission.

RESULTS. Follow-up of HTP showed initial and final platelet counts of 49000 ± 25840 (range 7000-12000/µL) and 196667 ± 104051 (range 32000-14000), p=0.004. There were no untoward haematological side effects. All HTP and 12 of 25 patients with normal platelets count showed PAI prior to therapy, and this situation stated unchanged after remission with Zidovudine. One patient developed thrombocytopenia of 6000/µL while under Zidovudine. Comparison between groups were:

	H T P / P A I +	NORMAL PLATELET COUNT	
		P A I +	P A I -
Homosexuals/Drugaddicts/Haemophiliacs	2/3/3	0/11/1	1/10/1
Age (years)	31 ± 10	29 ± 5	29 ± 6
AIDS and CRS case rate	12.5 %	42 %	36 %
CD4 count / µL	544 ± 300	600 ± 375	349 ± 285
Platelets / µL	49000 ± 25840	254000 ± 88000	254750 ± 86400

CONCLUSION. Zidovudine therapy appears highly effective to control HTP. The presence of PAI in that group is sensible but nonspecific. PAI may be present in every stage of HIV-infection and did non correlate with the degree of immunodefiency or with any specific group at risk,neither they disappeared with the remission of thrombocytopenia obtained with Zidovudine. Consequently, PAI pathogenic role remains unclear.

T.B.P.275 THERAPY OF HIV ASSOCIATED THROMBOCYTOPENIA

Lim Seng Gee, Lee, C A and Kernoff, P B A
Haemophilia Centre and Haemostasis Unit, Academic department of Haematology, Royal Free Hospital, London, United Kingdom

Objective To assess the therapy of HIV associated thrombocytopenia

Methods A retrospective analysis of 111 HIV positive haemophiliacs showed 7 with thrombocytopenia $< 50 \times 10^9$/L. 4 patients were CDC II, 1 was CDC III and 2 were CDC IV. Their mean age was 26years(range 5-38), and the they had been HIV positive for a mean of 63 months (range 47-90 months) 5 forms of treatment was used, as in table 1

Results Table 1 illustrates the results A transient response occured when the platelet count returned to pre-treatment levels, a partial response occured when the platelet count was maintained between 50-100 x 10^9/L, and a complete response occured when the platelet count was maintained above 100 x 10^9/L

no. of pts.	THERAPY	RESPONSE	side-effects
4	IV g-globulin	1 nil, 3 transient	nil
2	steroids	2 partial	nil
3	zidovudine	1 nil, 2 complete	1 pancytopenia
1	interferon	1 complete	flu-like symptoms
2	splenectomy	1 partial, 1 complete	1 subphrenic abscess

Table 1

Conclusions IV gammaglobulin and steroids were useful in obtaining a short term response, but splenectomy is the final treatment for the asymptomatic patient in the long term, although not without risk Zidovudine is non-invasive and effective therapy and therefore particularly suitable for the haemophiliac. Interferon appears promising and may be an alternative to zidovudine, but further studies are required

T.B.P.276 LACK OF EFFICACY OF ON-LINE COLUMN-A-ADSORPTION IN TREATMENT OF HIV-ASSOCIATED ITP

Scolaro, Michael J.* and Kennedy, P.*
*Los Angeles Oncologic Institute, St. Vincent Medical Center, Los Angeles, California 90057, U.S.A.

Objective. To determine the clinical efficacy of on-line CAA in restoring normal platelet count in patients with HIV-related ITP. Previous studies have demonstrated the value of off-line CAA in treatment of HIV-ITP.
Method. We treated 7 patients with ITP (platelet count range 18,000/cu mm to 85,000/cu mm, mean 39,000/cu mm) using an on-line IBM cell separator with Protein A column (Imre). Patients were treated 2-3 times weekly for a period of 3 to 5 weeks. Monitored parameters included platelet counts, platelet associated IgG and IgM, CICs, WBC and hemoglobin as well as physical examination and routine laboratory studies. Two patients with elevated platelet associated IgM in addition to elevated IgG underwent repeated plasmapheresis 2-3 times in addition to CAA.
Results. We observed modest increments (10,000-20,000/cu mm) in circulating platelets in 3 patients. But no dramatic or sustained increment was observed except for one patient whose count increased from 25,000/cu mm to 90,000/cu mm after CAA. No patient had post-treatment counts above 100,000/cu mm. There were no consistent changes in any of the other monitored objective parameters. Other than occasional rigors, no toxicities were observed. All patients noted a distinct subjective sense of improved well-being which was sustained after completion of CAA.
Conclusion. On-line CAA performed 2-3 times weekly for 3-5 weeks did not produce clinically meaningful increments in platelet count. Further work is needed to clarify the role of CAA in HIV-related autoimmune phenomena.

T.B.P.278 COMBINED STEROID-ZIDOVUDINE TREATMENT OF SEVERE THROMBOCYTOPENIA ASSOCIATED WITH HIV INFECTION.

Arrizabalaga, J.; Iribarren, J.A.; Santamaria J.M.; Zubero, Z.; Garde, C.; Zuloaga, D. Hospital Nuestra Señora de Aránzazu, San Sebastian, and Hospital Civil de Basurto, Bilbao, Spain.

Objective: Assessment of the efficacy of combined steroid-zidovudine treatment in patients with severe thrombocytopenia and HIV infection.
Methods: Since June 1988 a therapeutic protocol of steroids and zidovudine has been in effect for patients with HIV infection and severe thrombocytopenia (platelets under 20.10^9/L). Six patients were included in this study. In 3 of them the condition was discovered in a routine blood analysis. The other 3 patients consulted for clinical manifestations related to thrombocytopenia (1 cerebellar hematoma and 2 hemorrhagic diathesis). All began treatment with steroids at a dose of 1 mg/kg/day of prednisone, except for the patient with cerebellar hematoma, who began with hydrocortisone 4 mg/8 hours. Seven days after the onset of treatment, steroids began to be tapered off and zidovudine 200 mg/8 hr was associated. Steroids were suppressed on day 15.
Results: All patients presented an increased platelet count at the onset of steroid treatment, with a mean of 86.10^9/l (range $40\text{-}180.10^9$/l). After suspending steroids and during early zidovudine treatment, there was a decline in platelet counts, with a mean of 20.10^9/l (range $10\text{-}40.10^9$/l). At 2 months there was a new rise in the platelet count, which persisted at 3 months in all patients. This rise continued at 6 and 8 months in the patients who were treated this long.
Conclusions: Combined treatment of 2 weeks ed prednisone and continuation with zidovudine indefinitely is a useful alternative in patients who have severe thrombocytopenia associated with HIV infection.

T.B.P.280 TREATMENT OF LYMPHOMAS (NHL) ASSOCIATED WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV).

C.Gisselbrecht, E.Oksenhendler,JP.Farcet,H.Dombret,B.Coiffier,M.Raphael. Paris,Créteil,Lyon,Nice,France.
Supported by INSERM

NHL-HIV have a poor prognosis related to both lymphoma and associated opportunistic infections (OI).In order to evaluate the place of intensive chemotherapy in a subset of patients with NHL-HIV.Pts were stratified in 2 risk groups.Group A:no OI and performance status < 2 (OMS);group B:performance status > 2 or existence of OI.In group A,pts were treated with an intensive regimen LNH 84(ASCO,898,1988).In group B pts received a low dose chemotherapy program associated with AZT 600 mg,Adriamycin 25 mg/m²,d1,VM 26 30 mg/m²d1,Cyclophosphamide 300 mg/m²d1,Prednisone 20mg/m²d1-5,Vincristine 1,4 mg/m² d15,Bleomycine 10 mg/m² d15.In case of CNS involvement in both groups,cranial radiotherapy 40 gy was used.47 pts were included in the study,23 are presently evaluable.Histology: diffuse large cell 12 pts,IBL 5 pts,Burkitt 9 pts,Kil 1 pt, unclassified 4 pts.In group A stage was:I 3 pts,II 2 pts,IV 12 pts.Bone marrow 5 pts.CNS 6 pts.B Symptoms 13 pts,bulky disease 4 pts.After induction 12 pts are in CR,3 PR,2 failures,3 deaths. Infection grade 2-3 was observed in 10 pts,4 pts already died form progressive disease.In group B:3 pts,2 died at the onset of treatment.Intensive treatment in NHL-HIV pts is feasible.Updated results will be presented.

T.B.P.277 EFFICACITE DE LA ZIDOVUDINE A FAIBLE DOSE DANS LE TRAITEMENT DES THROMBOPENIES LIEES AU VIRUS HIV.

Routy JP* Blanc AP* Garabedian C* Maurice C* David M* Jolio Y**
* Hôpital Cézanne 13616 Aix-en-Provence France - CHG Salon de Pce France**

Objectifs : juger de l'effet et de la toxicité de la Zidovudine‡ à faible dose (2 gélules à 200mg q 8h), chez des patients asymptomatiques pour le virus HIV. Nous avons précedemment montré l'efficacité de la Zidovudine à dose classique (2 gélules q 4h) chez les patients SIDA et ARC. Une étude suisse contre placebo, retrouve les mêmes résultats. L'augmentation du taux des CD4 et la diminution de l'antigénémie HIV ont été observées pour des doses faibles de Zidovudine à 3 mois.
Méthodes : 8 patients asymptomatiques HIV+ (6 toxicomanes, 1 homosexuel, 1 transfusé) présentaient une thrombopénie isolée inférieure à 100000/ml. Le myélogramme confirmait l'origine périphérique de la thrombopénie. Les patients n'avaient ni hépatosplénomégalie ni trouble de la coagulation. La Zidovudine (2 gélules q8h) a été prescrite pendant 3 mois, suivie d'une fenêtre thérapeutique de 1 mois, puis reprise du même traitement.
Résultats : un taux de plaquettes supérieur à 100000/ml a été observé chez 7 patients, dans un cas les plaquettes ont augmenté mais restèrent inférieures à 100000/ml. Dans 5 cas la correction de la thrombopénie a été observé en moins d'un mois. A l'arrêt du traitement, 6 patients ont vu leurs plaquettes redevenir inférieures à 100000/ml puis remonter à la reprise du traitement. Aucune toxicité n'a été observée, les globules rouges et globules blancs restent stables le VGM a augmenté de 8fl. Conclusion : la Zidovudine à faible dose corrige les thrombopénies liées au virus HIV chez des patients HIV+, asymptoasymptomatiques, sans toxicité.

T.B.P.279 PHASE II STUDY OF ALPHA 2A INTERFERON (INF) ASSOCIATED WITH AZT IN PATIENTS (PTS) WITH AIDS RELATED KAPOSI'S SARCOMA.

Gonzalez-Canali, G.; Navarro-Carola, E.; De Gramont, A.; Demuynck, B.; Louvet, C.; Krulik, M.
Hopital Saint-Antoine - Paris - FRANCE

INF is the standard therapy for AIDS-KS and AZT has demonstrated antiviral activity in AIDS. 15 pts with AIDS-KS received alpha 2A INF (18 MU daily IM) associated with AZT 1200 mg orally (200 mg every 4 hs) daily. All pts had biopsy proven KS with a minimum of 2 measurable lesions. No pt presented a concurrent opportunistic infection and all had a performance status equal or below 1 (WHO), with a minimal 3 months life-expectancy. 11 pts had less than 400 T4 cells. Median age was 34 year-old (23-40). Risk factor for AIDS was homosexuallity in all cases. All pts were evaluable for toxicity and response. KS staging was : I = 10 pts; II = 4pts; III = 0 pt IV = 1pt. 8 out of 15 pts presented B symptoms (Krigel). Median duration of treatment has been 8 weeks (2-16 weeks). Clinical responses (PR + CR) were obtained in 11 pts (73 %) CR in 7 pts and PR in 4 pts. 6 pts responded between 4 and 4 weeks and the other 5 between 5 and 16. 3 pts remained stable and no pt developped progressive KS during treatment. Toxicity inclued mild flu-like symptoms in all pts during the first week and myalgia after the first month in 10 out of 15 pts (66 %). Leucopenia appeared after 4 weeks in 8 pts (53 %) associated with thrombopenia and anemia in 1 pt : AZT was reduced of 50 % and hematological status improved. This study shows high response rate with alpha 2A INF and AZT in AIDS-KS with tolerable toxicity.

T.B.P.281 CORRELATION OF EFFECTS OF INTERFERON-ALPHA IN AIDS-ASSOCIATED KAPOSI'S SARCOMA WITH SERUM LEVELS AND DOSE

Sawyer, Leigh*; Boone, E.*; Zoon, K.**; Metcalf, J.***; Lane, H.***; Quinnan, G., Jr.*; et al. *Division of Virology, CBER, FDA, **Division of Cytokine Biology, CBER, FDA, *** NIAID, NIH, Bethesda, MD, USA

Objective. To study the relationship between the dose and blood levels of interferon-alpha (IFN) to responses to treatment of patients with Kaposi's sarcoma (KS).
Methods. We studied 37 patients with KS enrolled in studies of IFN therapy alone and in combination with zidovudine (AZT). Sera for determination of IFN levels were collected from the 15 patients receiving IFN alone in the morning after bedtime doses at regular intervals during the period of study and from the 22 patients on IFN+AZT 12 hours after their dose.
Results. In the IFN alone study 8/8 responders (R) had sustained blood levels of ≥100 international units (IU)/ml of IFN for 8 weeks or longer compared to 1/7 nonresponders (NR) (P=0.001). The R received doses of IFN ≥$10X10^6$ IU/day more often than NR (P=0.005). In the IFN+AZT study, 6/13 R and 0/9 NR had levels ≥100 IU/ml (P=0.02). R were more likely than NR to have been on ≥$10X10^6$ IU/day (7/13 versus 1/9, P=0.005). There was no correlation between dose of AZT given and response. There was a high correlation between IFN dose and blood level in both studies (P<0.001). In the two studies combined among patients with ≥200 CD4+ lymphocytes/mm^3 at baseline, the response rate of those with serum levels ≥100 IU/ml was 11/13 (85%) compared to 7/18 (38%) for those with levels <100 IU/ml (P=0.01).
Conclusion. The dose and blood levels of IFN achieved and maintained may be important factors in determining responses of KS.

T.B.P.282

EFFICACY OF HIGH DOSE (50 MU/M2) INTRAVENOUS RECOMBINANT INTERFERON ALFA-2-b (HD.IV.rIFNα(2b)IN AIDS RELATED KAPOSI'S SARCOMA.

BEAUCAIRE Gilles*, CHIDIAC C.*, BRION J.P., LACUT J.Y., MASSIP P., and THE STUDY GROUP. *Department of Infectious Diseases. University of Lille. France.

Objectives : From March 1987 to December 1988, an open study was performed to assess the efficacy of HD.IV.rIFNα(2b that was given 5 days/week, every other week, in the treatment of AIDS related Kaposi's sarcoma (AIDS/KS).

Methods : The KS stages were ranged according to the KRIGEL classification with a special reference to absence(A) or presence(B) of constitutional symptoms and to dissemination rate (1,2 or 3). The response criteria, after at least a 12 weeks long treatment, were defined as follow : Complete response(CR=eradication of all previously detectable disease). Partial response(PR=50% decrease or more, in the biperpendiculare size and in the number of skin lesions). Stable disease (SD=less than PR or less than 25% increase in the size of the lesions). Progressive disease(PD= more than 50% increase in the size or number of lesions). CR and PR allowed for objective response (OR), SD and PD for failure (F). Thirty-four patients were initially enrolled but 13 were excluded, because of a less than 12 weeks (11) treatment duration or association with AZT (2). The remaining 21 patients were all men : 15 homo- and 6 bisexuals ; age(y)= 4.2 ± 5.3(27-48) ; weight(kg)=64.7 ± 7.4(50-77) ; size (cm)=175.3 ± 4.9(164-185). The distribution of the KS stages was :I(5),II(10),III(4) and IV(2); A(17) and B(4) ; 1(1), 2(13) and 3(6).

Results : The mean treatment duration and daily dose were respectively 5.67 months ± 2.5(3-13.5) and 88.62 MU ± 4.63(75-100). The KS evolution was as follow :OR =10(CR =3 and PR =7) ; F =11 (SD =6 and PD =5), with a statisticly significant difference between the IA + IIA KS stages versus all the others(P 0.01) and between the IA+IIA+IIIA KS stages versus all the others(P 0.05). Two patients died from KS visceral localizations while rIFN seemed efficient on the skin lesions.

Conclusion : HD.IV.rIFNα(2b seems to be the most effective in the IA and IIA, KS stages while its use seems less usefull in more advanced stages.

T.B.P.283

HIV-ANTIGENEMIA IN PATIENTS WITH AIDS-RELATED KAPOSI'S SARCOMA (KS) TREATED WITH RECOMBINANT ALPHA-2a INTERFERON (IFN).

Rozenbaum Willy, Gharakhanian S., Rouzioux C., De Sahb R., Bugard M., Cardon B. Infectious Disease Unit, Rothschild Hosp.; Virology lab, Necker Hosp.; Paris, France.

OBJECTIVE To assess the link between HIV antigen (Ag) level and clinical response to IFN in KS.

METHODS 76 males, mean age 37.5, were treated for biopsy-proven KS with 18M units a day of IFN during a mean of 168±77 days. Ag was assessed before and during treatment, measured blind by the Abbott technique with concentrations calculated by linear regression (pg/ml). CHI² and t-test comparisons were performed.

RESULTS Before treatment, 49 pts were Ag positive (Ag-P) and 27 Ag-negative (Ag-N). The two groups groups were comparable in CD4 counts and clinical stage of KS. A complete response (CR) was observed in 52% of the Ag-N group but in only 29% of the Ag-P group. Evolutive disease was observed in 43% of Ag-P and 19% of Ag-N pts (Table I). Of the 5 Ag-N patients who had evolutive lesions, 4 became Ag-P. Overall, Ag levels were lower during IFN therapy (185pg/ml) than before (395.5pg/ml) (p 0.001). In the Ag-P group, the drop was significantly greater in pts with a CR, and 7 of the 9 pts who became Ag-N had a CR.

TABLE I

	COMPLETE RESPONSE	MODERATE RESPONSE	STABILIZATION	EVOLUTIVE DISEASE
Ag-N	[illegible]	[illegible]	3	[illegible]
Ag-P	[illegible]	7	[illegible]	[illegible]

p < [illegible]

TABLE II

RESPONDERS (%)	N (pts)	INITIAL Ag pg/ml	END TREATMENT Ag pg/ml	% DECREASE Ag	P
Complete R	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Moderate R	7	1330	[illegible]	[illegible]	[illegible]
Stabilization & Evolutive Disease	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
TOTAL	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

CONCLUSION We demonstrate that KS is more likely to respond to IFN if initial HIV Ag is negative Pts who become positive during therapy are less likely to respond. Generally, in Ag-P pts, the Ag level drops during treatment; the % drop is proportional to the likelihood of a CR.

T.B.P.284

CHEMOTHERAPY WITH OR WITHOUT GRANULOCYTE-MACROPHAGE COLONY STIMULATING FACTOR (rGM-CSF) IN PATIENTS WITH AIDS-ASSOCIATED NON-HODGKIN'S LYMPHOMA (NHL).

Kaplan, Lawrence D*, Kahn JO*, Grossberg H**, Volberding PA*. Department of Medicine*, San Francisco General Hospital, San Francisco, CA and Schering-Plough Corporation**, Kenilworth, NJ, U.S.A.

Objective: To determine whether rGM-CSF can reduce chemotherapy-induced myelosuppression in patients with AIDS-associated NHL.

Methods: Patients were randomized to receive CHOP (Cyclophosphamide $1g/m^2/d1$, Doxorubicin $40mg/m^2/d2$, vincristine 2mg, Prednisone $100mg/m^2/d1\text{-}5$) with or without rGM-CSF 10-15mcg/kg subcutaneously day 1-10.

Results: Six of the planned 20 patients were randomized. No patient had a prior AIDS diagnosis. Patients in the control group had higher mean T4 counts ($618/mm^3$) than those in the rGM-CSF group ($204/mm^3$). In 9 chemotherapy cycles administered to 3 patients without rGM-CSF, the mean nadir ANC was $1.06 \times 10^3/mm^3$ compared to $1.53 \times 10^3/mm^3$ in 3 treated with rGM-CSF. Two rGM-CSF-treated patients became neutropenic: Patient 1 had $ANC<1000/mm^3$ for 20 days at 7.5 mcg/kg GM-CSF, 12 days at 10mcg, and 5 days at 15mcg. Patient 2 had $ANC<1000/mm^3$ for 9 days at 10mcg and 4 days at 15mcg. After 3 cycles, a third rGM-CSF-treated patient had a mean 10 day ANC of $4.3 \times 10^3/mm^3$. HIV-related opportunistic infections were not observed. Hospitalization for fever and neutropenia complicated 2/3, 1/3, and 0/3 chemotherapy cycles in the 3 rGM-CSF-treated patients and 0/6, 0/2, and 1/1 cycles in the 3 control patients. Toxicities related to rGM-CSF included fatigue (1 patient), pericarditis (1), and thrombocytopenia (1).

Conclusion: Response to rGM-CSF administered with chemotherapy is variable. While severe neutropenia is not always prevented, its duration may be shortened. This trial is ongoing.

T.B.P.285

ADOPTIVE TRANSFER OF IMMUNITY TO RECALL ANTIGENS FOLLOWING ALLOGENEIC BONE MARROW TRANSPLANTATION (BMT) IN AN AIDS PATIENT WITH NON-HODGKIN'S LYMPHOMA (NHL)

Donnenberg AD, Holland HK, Burns WH, Santos GW and Saral R
The Johns Hopkins University, Baltimore, MD, USA.

Objectives. We have previously shown that transfer of donor immunity can be reproducibly achieved after allogeneic BMT by boosting the BM donor before transplant and/or the recipient on the day of BMT. The present study was conducted on a 41 yo HIV-1 culture⁺ man with NHL who received combined modality therapy of allogeneic BMT plus azidothymidine (see separate abstract, this meeting). The main objective was to determine whether transfer of donor cell mediated and humoral responses to tetanus (TET) and diphtheria (DIP) toxoids could be attained in a patient in whose natural responses to these antigens had been ablated by HIV-1 disease.

Methods. Serum IgG was measured by nephelometry. HIV-1 antibody was measured by immunoblot and quantified by densitometry. TET and DIP antibody was measured weekly by ELISA. Antigen specific proliferating lymphocytes (ASPL) were measured weekly by ^{3}HTdR uptake. The BM donor was boosted i.m. with TET and DIP on day -8; the recipient with TET alone on the day of transplant.

Results. Before BMT IgG was elevated (1440 mg/dL) but TET and DIP antibodies were 10-fold lower than control reference values. TET and DIP ASPL were absent. After BMT, total IgG and HIV-1 antibody declined by half, consistent with clearance of host antibody. TET and DIP antibody rose >4-fold and were maintained above pretransplant levels. TET and DIP ASPL were detected 5 wks after BMT (>3000 CPM) and persisted until death from tumor relapse at wk 8.

Conclusion. These data indicate successful transfer of immunogen specific donor immunity and reconstitution of responses ablated by HIV-1 disease.

T.B.P.286

CARBON MONOXIDE DIFFUSING CAPACITY (DLCO) AS A PREDICTOR OF LUNG FUNCTION IN PATIENTS RECEIVING BLEOMYCIN FOR TREATMENT OF KAPOSI'S SARCOMA.

AM. Bisher; Ireland-Gill A; Espinar BE; Gill P. University of Southern California, Los Angeles, California 90033.

Objectives: The purpose of this study was to evaluate the effect of Bleomycin-containing chemotherapeutic regimens on the pulmonary function in patients with Kaposi's Sarcoma (KS) associated with AIDS.

Methods: We evaluated 19 patients who had at least two sets of Pulmonary Function Tests (PFT's) one before and after receiving chemotherapy.In addition data was collected for other factors that can alter PFT's, including presence of pulmonary KS, prior lung infections, as well as lung infection during therapy. Two groups were identified; Group I receiving cumulative Bleomycin over 100 unit (mean 184 units) and the other, Group II receiving less than 100 units (mean 41 units). Both groups were comparable in all characteristic, stage of infection, and laboratory markers. PFT's studies included spirometry, lung volumes and diffusion studies. All patients were given prophylaxis against *Pneumocystis carinii* pneumonia (PCP).

Results: Two patients from Group I developed PCP while on study (17%), none from Group II. Analysis of PFT's revealed the only consistent alteration was that of DLCO ($P < 0.002$). A decline of 25-80% in the DLCO was seen in all patients in Group I.

Conclusion: 1. Cumulative dose of Bleomycin >100 is always associated with a decline in DLCO.
2. Patients with AIDS-related KS receiving Bleomycin should be monitored for pulmonary toxicity with DLCO, especially after receiving a cumulative dose of > 100 units.

T.B.P.287

REGRESSION OF KAPOSI'S SARCOMA (KS) FOLLOWING PROSORBA® COLUMN TREATMENTS.

Reed, David E.; Snyder, H.W., Jr.; Balint, J.P., Jr.; Jones, F.R. and the PROSORBA Clinical Trial Group. IMRÉ Corporation, Seattle, WA, USA.

Objective - To modulate immune system activity and induce regression of KS by removal of IgG and circulating immune complexes (CIC) from patient plasma.

Methods - A clinical trial of immunoadsorption of plasma was carried out with 23 patients who had progressive KS and had received no anti-tumor or anti-viral therapy. Patients received 12 treatments, consisting of adsorption of 250-2000 ml plasma, using the U.S. FDA approved PROSORBA® column over a 4 week period.

Results - Significant regression of KS was observed in 9 patients (6 PR and 3<PR). New lesions appeared in only 4 patients. Lesions developed a reddish halo, flattened and became lighter in color. Reduction in size was accompanied by central umbilication. Some lesions disappeared completely. Responses were seen in all stages of disease; one patient with Stage IV KS survived with stable disease greater than 4 years. Responses were associated with increases in NK cell activity, granulocytes, lymphocytes and T_H/T_S ratio.

Conclusion - Extracorporeal immunoadsorption of IgG and CIC is a beneficial new treatment modality for AIDS-KS.

T.B.P.288

ADVERSE REACTIONS WITH HIGH DOSE (90MU/M2) INTRAVENOUS RECOMBINANT INTERFERON ALFA 2b (HD.IV.rIFNα2b) IN AIDS RELATED KAPOSI'S SARCOMA.

BEAUCAIRE Gilles*, MOUTON Y.*, BIRON F., LEPEU G., REYNES J., and THE STUDY GROUP. *Department of Infectious Diseases. University of Lille. France.

Objectives : From March 1987 to December 1988, an open study was performed to appraise the efficacy and the tolerance of HD.IV.rIFNα2b, that was given 5 days/week, every other week, in the treatment of AIDS related Kaposi's sarcoma (AIDS/KS).
Methods : The 34 initially enrolled patients were all men : 25 homo- and 9 bisexuals ; age(y)= 36 ± 7.8(22-55) ; weight(Kg)=62.3 ± 7.6(49-77) ; size(Cm)=173.6 ± 5.8(161-185). Ten patients experienced 1 or more opportunistic infections (OIs). According to the KRIGEL classification, with a special reference to absence(A) or presence(B) of constitutional symptoms and to dissemination rate (1,2 or3), the distribution of the patients was :I(7), II(15), III(7), and IV(5) ; A(21) and B(13) ;1(1),2(20) and 3(13). The mean treatment duration and daily dose were respectively 4.10 months ± 2.65(0.5-13.5) and 87.15 MU ± 4.8(75-100). All the adverse reactions were evaluated according to the OMS scale.
Results : During the study, 13 infections occured in 12 patients, 7 of them were in IVC1 or IVC2 status before treatment, with only 5 OIs in 5 patients, all in IVC1(4) or IVC2(1) status. Thirty patients presented 41 clinical side effects : fever(23) with 13 cases in form of flu-like symptoms (chills, malaise, myalgias, headache) ; psychological intolerance to the treatment(6) ; transient paresthesias(1) ; confusion and anxiety(2) ; anorexia(2) ; nausea and vomiting(2) ; non productive cough(1) ; conjonctival hyperhaemia(1) ; taste alteration(1); periorbicular pain (1), insomnia(1). Thirty patients presented 71 biological drug related toxicity signs : myelosuppression in 26 patients -leucopenia(22), neutropenia(23), anemia(10), thrombopenia(5)- ; mild hepatotoxicity in 7 patients - cytolysis(3), retention(6) - ; eosinophilia(1) ; amylasemia(1).
Conclusion : Adverse reactions conducted to discontinue the treatment in only 7 patients : psychological intolerance(6) and deep myelosupression(1).

T.B.P.289

HIGH DOSES OF INTERFERON ALFA 2-b IN KAPOSI'S SARCOMA

Ocaña I., De Luis A., Ruiz I., Bejarano E., De Buen L (*), Martinez Vazquez J.M.

Departments of Internal Medicine and Microbiology (*), Hospital Vall d'Hebrón, Barcelona, Spain.

The efficacy anf safety of Interferon alfa 2-b (Intron A) were evaluated in patients with AIDS related Kaposi's sarcoma (KS).
METHODS: from June 1986 to December 1988, 9 patients (8 homosexual or bisexual men and 1 drug-addict woman) were included in this trial. The mean age was 32 years (20-41 Yrs). The KS stages (Krigel et al.) were: stage I: 1 pt, stage II: 2 pts, stage III: 1 pt, stage IV: 5 pts. Highdose Interferon alfa 2-b (50 mu/SQM) was administered IV daily for 5 days every other week during at least 4 cycles (mean number of cycles: 14, range: 4-39).
RESULTS: following Volberding's criteria for response, a complete response (CR) was seen in 4 pts (44.4%), a partial response (PR) in 2 pts (22.2%) and disease progression on 3 pts (33.3%). All the CR were seen in stages I-II or III with less than 15 skin lesions and with a mean pretreatment CD4 cells count of 354 (93-663). The disease progressed in all the patients with stage IV B, presenting with lung and/or liver lesions with a mean pretreatment CD4 cells count of 85 (25-129).
The treatment was well tolerated in all patients with only fever and myalgia which required symptomatic treatment, without any dosage modification. In 7 pts the p24 antigen levels were monitored; 2 pts showed a 50% decrease in their p24 levels, 1 pt presented a persistent clearing in its level and in the other 4 pts the p24 levels remained stable with a dramatic increase in 1 pt before death.
CONCLUSIONS: high dose Interferon alfa 2-b is an effective and welltolerated treatment of AIDS related Kaposi's sarcoma with an antitumor and antiretroviral effect.

T.B.P.290

INTRALESIONAL VINBLASTINE (VELBAN) TREATMENT OF LESIONS OF KAPOSI'S SARCOMA

Conant, M. A.; Galzagorry, G.; Illeman, M.
University of California, San Francisco, California, U.S.A.

Objective. To determine effectiveness and safety of using Vinblastine (Velban) therapy intralesionally into individual lesions of Kaposi's sarcoma.
Methods. Fifteen subjects with previously diagnosed Kaposi's sarcoma and positive HIV antibody tests were entered into the study. Lesions of Kaposi's sarcoma of any cutaneous surface (including oral mucosa) were injected with Vinblastine 0.1-0.4 mg/ml at intervals of two weeks. Injections continued for 5-8 treatments, or until desirable results were obtained. At each two-week visit, photographs were taken of five specific lesions. The lesions were evaluated for size, induration, and color. Both local and systemic side effects were rated on a scale of 1 to 5. A pretreatment CBC and SMAC were drawn, as well as a CBC at each visit to determine systemic effects from Velban therapy.
Results. Hematological safety data and photographic evidence of efficacy will be displayed.
Conclusion. Intralesional Velban is effective in reducing the size, color and induration of individual KS lesions with minimal systemic side effects. It is easily administered, and offers both the patient and provider an additional treatment modality for an emotionally difficult and often painful manifestation of HIV disease.

T.B.P.291

REMISSION OF KAPOSI-SARCOMA BY A COMBINED THERAPY WITH INTERFERON-BETA + AZT IN AN AIDSPATIENT

Jaschke, Heribert*; Broeck, F. **.
*Hem.-Onc. Institute. Aachen. FRG; ** INSTO. Institute for Organisation. med. dep. . Aachen. FRG.

We report the case of an HIV-1-infected patient with Kaposi-Sarcoma (KS), who was treated with human fibroblast interferon-beta (IFN-β, FIBLAFERON(R), Dr. Rentschler, Laupheim, FRG) + AZT (RETROVIR(R), Wellcome, Burgwedel, FRG).

The HIV-1-infection of the 25-years-old man is known for two years. He developped ARC with diarrhoea, night-sweats, relapsing infections of the respiratory system, p24-emia and drop of T4-counts and T4/T8-ratio. September '88 KS's of the larynx, gums, left temple, left shoulder and upper thighs appeared and were histologically verified.

IFN-beta-therapy was started with 2MU iv 3qw plus 1MU 3qw intralesional into the gum-tumors.
We noticed progression of the KS's three weeks after the beginning of the IFN-treatment.
Therefore the dosis was raised to 3MU iv 5qw plus 1MU sc 5qw into the gums.
The KS of the larynx was treated with radiatio (17 MeV) 8x 2Gy within 12 days.
From the very beginning of the IFN-treatment the patient got 4x 250 mg AZT/d in addition.

All lesions showed a complete and persistent remission after eight weeks of treatment.

Since December '88 the therapy is contined with 6MU IFN-beta iv 3qw.
No severe side effects were observed.
Since the beginning of the therapy there is an increase in T4-count and T4/T8-ratio and a decrease in β2-Microglobuline- and p24-titre, no change in other laboratory parameters.

T.B.P.292

INTERFERON ADMINISTERED INTRALESIONALLY IN SKIN, CONJUNCTIVA AND ORAL CAVITY LESIONS IN PATIENTS WITH AIDS-RELATED KAPOSI'S SARCOMA.

Sulis E*, Floris C*, Sulis ML*, Tedde A*, Turno R*, Contu L°. * Div. Medicina I, Osp. Oncol. "A. Businco", USL 21, Cagliari, Italy; ° Clinica Medica II, Cagliari, Italy.

The efficacy of interferon (IFN) in the therapy of AIDS related Kaposi's Sarcoma (AIDS-KS) seems to be dose-dependent. The concentration of massive doses of IFN in the tumoral lesions by intralesional injection seems to be a rational approach.

We have treated 9 male patients (average age 24 years, heterosexuals, drug addicts, anti-HIV seropositive, median OKT4/OKT8 0.75, without opportunistic infections) with skin, conjunctive and/or oral cavity lesions from AIDS-KS. Some lesions have been treated with IFN alpha 2b (from 3 to 5 millions of units 3 times/week for 4 weeks, according to the lesion volume), others with placebo.

All lesions treated with IFN cleared, while those treated with placebo did not. No relapse has been observed after an average of 12 months from treatment. Histological examination showed substitution of the IFN treated tumor nodules with fibrotic tissue.

The use of intralesional IFN therapy in AIDS-KS seems to be very useful, with mild adverse effects and it can be a valid alternative to chemotherapy in the disease localized in skin, conjunctive and oral cavity.

In our cases the activity of IFN seems to be local and related to the massive concentration of IFN in the tumoral lesion, where it explicates its antiproliferative activity at the best.

T.B.P.293

TITLE: **Assessment of the management of Kaposi's Sarcoma (KS)in AIDS patients.**

AUTHORS:: I.GARCIA-POLO,I.SANTOS,C.del ARCO,J.FRAGA,J.FERNANDEZ and A. NOGUERADO.
HOSPITAL DE LA PRINCESA,-M.INTERNA,UNIVERSIDAD AUTONOMA,MADRID-SPAIN.

OBJETIVES:To assess the usefulness of Zidovudine (ZDV) and Interferon (IF) in patients with KS associated to AIDS.
PATIENTS AND METHODS: 17 patients aged 24-44 years (mean 34,3), without previous oportunistic infection with histologically proven: KS. 7 patients received ZDV - only 0.200 mg/day) and 4 patients with more advance stages of the diseease. received also IF 30 MU/day. 6 patients received no therapy.
RESULTS: (Treated patients):

WEEK	IMPROVED	UNCHANGED	WORSE	DIED
4th (*)	1/11	8/11	2/11	0
12th(**)	3/9	2/9	4/9	0
24th(***)	1/8	2/8	5/8	2
48th	0/3	2/3	1/3	0
60th	0	1/1	0	0

(*)-Only two patients received IF from week 4.
(**)-One patient started on IF - from week 12.
(***)-One patient started on IF- from week 24.

CONCLUSIONS: Patients treated with ZDV remain stable or improve along the first four weeks (81%). some of them continue to do so up to the 12th. week (56%). A minority remain stable on the 24th. week (37,50%). IF does not add any benefits when added at high doses in advanced stages of KS.

Thérapie et évaluation clinique : ribavarine et autres médicaments
Therapy and Clinical Evaluation, HIV Ribavirin and Other Drugs

T.B.P.294 COMPARISON OF RIBAVIRIN VERSUS PLACEBO FOR PREVENTING THE PROGRESSION OF HIV INFECTED SUBJECTS FROM CDC STAGE III TO STAGE IV.

Spanish Ribavirin Study Group. Barcelona,Madrid,Bilbao,San Sebastian, Spain.

OBJECTIVE. To compare the efficacy of ribavirin versus placebo to prevent the progression of HIV-infected patients from CDC stage III to stage IV.
METHODS. 131 HIV-infected patients (20% homosexuals, 64% drug addicts) on CDC stage III, and a CD4 cell count between 50 and 500 per mm3 were included in a double blind multicentric trial and randomly allocated to receive ribavirin (15 mg/kg) or placebo. The planned duration of the study was 12 months with an interim analysis at 6 months without opening the codes unless a significant difference in efficacy or toxicity were detected. The Student-t test, the chi-square test, life-table analysis and the Mantel-Cox test were used in the statistical analysis.
RESULTS. The 63 patients included in the study group A and the 68 included in group B had a similar age, sex, red, white and CD4 blood cell counts. In the interim analysis 12 (19%) of the 63 patients of group A progressed to stage IV (8 to stage IV-C2,1 to IV-A and 3 to IV-C1) versus 11 (16%) of the 68 patients of group B (3 to stage IV-C2,3 to IV-A and 5 to IV-C1). The difference was not statistically significant pooling together all patients progressing to stage IV or performing a separate analysis for those reaching the CDC stage IV-C1. Side effects were irrelevant in both study groups.
CONCLUSION. At the interim analysis performed at 6 months both ribavirin (15 mg/kg per day) and placebo were well tolerated but the progression rate to stage IV was not statistically different. The results of the final analysis at 12 months will be presented in the Conference.

T.B.P.295 DEXTRAN SULFATE IS POORLY ABSORBED AFTER ORAL ADMINISTRATION

Lorentsen,Kevin*; Hendrix,C.*; Collins,J.**; Eckel,R.***; Petty,B.*; Lietman,P.*; et al.
*Johns Hopkins University, Baltimore, MD; **U.S. Food and Drug Administration, Rockville, MD; ***University of Colorado, Denver, CO, USA.

Objective. To determine whether dextran sulfate, a synthetic analogue of heparin with anti-human immunodeficiency virus activity *in vitro*, is absorbed after oral administration.
Methods. Volunteers were given an 1800 mg. oral dose followed forty-eight hours later by a 225 mg. intravenous infusion of dextran sulfate. Because dextran sulfate is an anticoagulant and the activated partial thromboplastin time (APTT) is a sensitive measure of its anticoagulant activity we measured changes in the APTT after each dose. We also measured plasma lipase activity because dextran sulfate causes the release of lipases into the plasma.
Results. After the oral dose the APTT's were indistinguishable from the normal variation in this assay over time. In contrast the mean peak APTT was prolonged 142 seconds after the intravenous dose. Because we have observed a linear relationship between the log APTT and the plasma concentration of dextran sulfate *in vitro*, we used this assay to calculate plasma dextran sulfate concentrations, and we used these values to determine the bioavailability of this drug. While the mean bioavailability was 0.7% (range 0-2.2%), this small percentage could not be distinguished from 0%. Lipase activities increased to 2.3 X baseline after the oral dose and >400 X baseline after the intravenous dose.
Conclusion. We conclude that dextran sulfate is very poorly absorbed after oral administration.

T.B.P.296 RIBAVIRIN DOSE ESCALATING PHASE I TRIAL IN PATIENTS WITH AIDS AND ARC

Crumpacker, Clyde*; Cotton D*; Pearlstein G*; Valentine F**; Mills J+; and Spector S++. *Beth Israel Hospital, Boston, MA **NYU, New York, +San Francisco General,++UC San Diego, and NIAID ACTG-Bethesda, MD. U.S.A.

Objective. To carry out an increasing dose phase I trial to find maximum tolerated dose of Ribavirin (RBV).
Methods. Patients in 3 arms, 1) AIDS no previous treatment; 2) ARC; 3) AIDS, AZT failures; were enrolled in a 6 month trial of RBV 800, 1200, 1600, or 2000 mg/d with a goal of 24 patient per dose regimen. Patients all had serum p24 ≥ 70 pg/ml at entry. Clinical status, serum p24, HIV culture, total $CD4^+$ cells were measured in all patients at 4 weekly intervals. Pharmacokinetic values were measured in plasma and RBC by radioimmunoassay.
Results. As of 2/1/89, 28 patients were enrolled in the trial. All were in dose range 800 and 1200mg/d. Patients with AIDS-no previous treatment (10), severe ARC (10), and AZT failures (8) are receiving drug. Main side effect has been a pruritic rash at 1200mg/d requiring lowering dosage in 4 patients. In 100 patient months 2 episodes of PCP, 1 HSV, 1 CMV and 1 candida infection have occurred. No anemia or granulocytopenia requiring transfusion has occurred. Serum p24 levels have decreased in 3 patients, but trends of all serum p24 values increase with time. $CD4^+$ cells have increased in 2 patients, but trend of all values is a decrease with time. Pharmacokinetic data on 800mg/d reveal a steady state plasma level of 10-14uM.
Conclusion. RBV at 800 and 1200mg/d is well tolerated and is less than MTD. No severe granulocytopenia anemia, or neuropathy has occurred. Patients are having few opportunistic infections but KS progresses. Patients are continuing to be followed for $CD4^+$ cell changes

T.B.P.297 PHASE I STUDY OF 2', 3' DIDEOXYINOSINE (ddI) GIVEN ONCE DAILY TO PATIENTS WITH AIDS OR ARC.

Cooley, Timothy*; Saunders, C.A.*; Perkins, C.J.*; McCaffery, R.P.*; McLaren, C.**; Liebman, H.A.*. *Boston University School of Medicine, Boston, MA, USA; **Bristol-Myers Company, Wallingford, CT, USA.

Objective. To determine maximum tolerated dose (MTD), pharmacokinetics (PK) and efficacy of iv and oral ddI given once daily.
Methods. To date, 8 patients (6 men, 2 women) with AIDS (4) or ARC (4) were treated. Plasma and urine were collected after initial iv infusion and at steady state doses of 0.8 (1), 2 (5), 3.5 (2) mg/kg/d and after initial po dose and steady state doses of 1.6 (1), 4 (4), and 7 (2) mg/kg/d. Serial T4 lymphocytyes (T4L) and p24 antigen were studied.
Results. Pre-ddI T4L: mean = 106/mm3, range = 2-390/mm3. After 14 days of iv ddI, T4L rose in 4 pts, mean rise = 28/mm3, range= 10-57/mm3. After 2-16 weeks of po ddI, T4L rose in 3 pts, mean rise = 90/mm3, range 20-150/mm3. Pre-ddI: 2 p24 ag positive pts; no change on iv ddI; 1 on po ddI became p24 ag negative. PK data to follow. Hairy leukoplakia resolved in 2. Dose limiting toxicity: grade 2 cutaneous (1) and grade 2 hepatic (1). ddI was discontinued in 1 pt with HIV cardiomyopathy and EKG changes.
Conclusion. Daily ddI is well-tolerated in pts with AIDS and ARC with minimal toxicity. The MTD has yet to be established. Preliminary data suggest efficacy with increase in T4L. Pt accrual continues with further dose escalations.

T.B.P.298 EVALUATION OF MEGESTROL ACETATE TREATMENT IN AIDS

Gold, J., Oliver, C..
Albion Street (AIDS) Centre, Sydney Hospital, Sydney, Australia.

Objective. To evaluate the components of weight gain associated with megestrol acetate therapy in cachexic males with stage IV HIV disease.

Methods. Ten males with a weight loss of 15-20% of usual weight due to late stage HIV disease were treated with megestrol acetate (80 mg, three times a day). Subjects were treated as out-patients. All patients were on concomitant therapy, (AZT ± PCP prophylaxis). Baseline data obtained pre-therapy included blood biochemistry and haematology, and food intake by dairy. Subjects had an anthropometric assessment as well as body composition analysis by bioelectrical impedance. Subjects were requested to complete questionnaires regarding quality of life assessment, and factors affecting food intake.

Results. Results for a mean period of 12 weeks therapy per subject will be discussed. In addition results of weight gain and more specific indicators of body composition are presented to indicate exactly how megestrol acetate affects nutritional status.

T.B.P.299 RECOMBINANT GRANULOCYTE-MACROPHAGE COLONY-STIMULATING FACTOR (GM-CSF): LACK OF NEUROLOGICAL TOXICITY

Brew, Bruce J*; Keilp, JG*; Sadler, AE*; Krown, SE*; Anselmo, W*; Birnhak, L*; Sidtis, JJ*; Price, RW*; Bonnem, E**. *Memorial Sloan-Kettering Cancer Center, NY and **Schering Corporation, Kenilworth, NJ.

Objective: To assess the possibility of neurological toxicity of GM-CSF in neutropenic AIDS patients without dementia.
Methods: Patients enrolled in a phase 1 trial of GM-CSF as treatment for AIDS-related neutropenia were evaluated by quantitative neurological and neuropsychological assessment before and after each treatment cycle. GM-CSF was given by daily sc injection for 10 days followed by an 18 day rest period. Subsequent treatments were in 28 day cycles. Four patients were receiving concomitant azidothymidine (AZT). Patients with AIDS Dementia Complex (ADC) (Stage 1-mild, or greater) were excluded.
Results: Nine patients were evaluated: 5 were seen three times and one patient each was seen twice, four, five and six times. All patients at baseline had minor neurological signs such as eye movement abnormalities and slowing of limb movements (ADC Stage 0.5). None had cognitive complaints. No significant changes were seen in either the neurological or neuropsychological impairment scores.
Conclusions: Theoretical concerns have been expressed that GM-CSF might activate latent HIV-1 infection in macrophages and thereby lead to brain infection and ADC. However, this initial study found no evidence that GM-CSF exacerbated the minimal ADC-related neurological signs present at baseline, or led to ADC. These findings provide a basis for subsequent studies of GM-CSF and AZT in patients with ADC whose neutropenia precludes AZT.

T.B.P.300 OCCUPATIONAL THERAPY FOR PEOPLE WITH AIDS

Jonathan Jacobs; Lebowitz, V. Center for Special Studies, New York, NY, USA

Objective. To maintain and/or improve functional independence and quality of life for HIV+/AIDS patients and their families. To be cost effective by decreasing frequency and length of hospital admissions and hours of home health care needed. Methods. Occupational therapy as a component of Rehabilitation Medicine, assists the psychologically and physically disabled individual/family in achieving independence and quality of life, via a variety of modalities. These include but are not limited to: 1) Compensatory strategies for performing Activities of Daily Living (ADL) (ie- one handed techniques, adapted equipment, ADL for the blind) 2) Ordering of bathroom equipment to assist family members in maintaining safety and ease of transfers. 3) Recommendation of wheelchair and positioning devices. 4) Building functional strength and endurance. 5) Teaching energy conservation to the patient with shortness of breath and fatigue. 6) Instructing in stress management skills. 7) teaching leisure skills to increase productive use of time. Patients are seen weekly at an outpatient center or as inpatients as need, and determined by therapist and psychiatrist. Results. Based on formal written evaluations, documented in the medical charts: Patients and families demonstrate an increased independence in ADL's as a result of increased knowledge and adaptive equipment as needed. Through such devices as an adaptive pillbox timer, patients no longer require a home health aide to administer or supervise medications. Drug users find purpose in creative projects. Families learn to mobilize weak and paralyzed patient safely. Conclusion. Occupational therapy as a discipline of rehabilitation medicine, helps people with AIDS and their families achieve quality of life and a greater level of independence. This service is cost effective as it decreases the need for home health care nursing and amount and length of hospital admissions...

T.B.P.301 SUPERVISED PHYSICAL EXERCISE LEADS TO PSYCHOLOGICAL AND IMMUNOLOGICAL IMPROVEMENT IN PRE-AIDS PATIENTS.

Schlenzig, Carla*; Jäger, H.**; Rieder, H.*; Hammel, G.** and Popescu, M**.
*University of Heidelberg, Heidelberg, FRG, **AIDS Study Group, Schwabinger Krankenhaus, Munich, FRG.

Objective. The immunological and psychological effects of therapeutically supervised physical exercise in HIV-AB positive individuals were investigated in a randomized controlled prospective study.

Methods. Twenty-eight HIV-AB positive patients were stratified according to the Walter-Reed-Staging-Classification (Stages 1 through 4 were included). Fifteen subjects were randomly assigned to participate in one-hour physical exercise sessions twice a week over a period of 8 weeks. The exercise program was designed to develop endurance beyond threshold value of 4 mmol lactate. The control group of 13 patients did not receive exercise treatment.

Results. Within the first 4 weeks the number of CD4+ cells increased in 67% of subjects receiving therapy, as compared to 58% of the control group. CD4+/CD8+ ratio of the test group increased from 0.46 to 0.47 while the ratio in control subjects decreased from 0.49 to 0.43. In addition delayed cutaneous hypersensitivity reactions measured by recall antigens (Multitest Merieux) increased (from 12.8/2 to 16.2/3).There was a clear psychological benefit concerning reduction of anxiety and depression as well as build up of a group feeling. POMS, a psychological symptoms inventory, showed delayed, but strong correlation with changes in the immunological parameters.

Conclusion. These results demonstrate that carefully directed physical exercise can improve both immunological and psychological parameters in HIV-infected patients.

T.B.P.302 LONG TERM RIBAVIRIN TREATMENT

Bánhegyi D[x], Lendvay J[x], Ujhelyi E[xx], Füst Gy[xx], Mihály I[x], Várnai F[x]
[x]Institute for Infectious and Tropical Diseases, Postgraduate Medical School, [xx]National Institute for Haematology and Blood Transfusion, Budapest, Hungary.

Objective To evaluate clinical efficacy, safety and tolerance of long term ribavirin treatment.

Methods Four patients /pts/ /stage III-3 stage IVA-1/ were treated with 600 mg/day ribavirin orally. Number and ratio of CD4+ and CD8+ lymphocytes, serum levels of immunglobulines, neopterin and HIV p24 antigen were determined monthly as well as clinical assessments, clinical chemistry, haematology, parasitology and bacteriology were investigated.

Results Three pts were treated for 24 one for 13 months. The overall conditions of the pts improved, no serious infection of opportunistic disease were observed /the AIDS pt's cryptosporidial diarrhea stopped/ however oral hairy leukoplaky developed in two pts. CD4+ cell count and ratio stabilised in 3 pts and significantly elevated in one. Two pts had been and remained positive, one pt became HIV p24 antigen positive after 12 months and one pt was negative. The pts tolerated ribavirin treatment extreamly well, no side effects, not even anaemia were observed.

Conclusion Ribavirin might be of use in the long term treatment of pts in stage III. Neither adverse reaction, nor side effects have been observed.

T.B.P.303 A PHASE I STUDY OF THE SAFETY AND PHARMACOKINETICS OF SOLUBLE RECOMBINANT CD4 (rCD4) IN PATIENTS WITH AIDS AND ARC.

Allan, J. Davis*; Kahn, J**; Hodges, T*; Sherwin, S***; Volberding, P**; and Groopman, J*. *New England Deaconess Hospital, Boston, MA; **San Francisco General Hospital, San Francisco, CA; ***Genentech, Inc., South San Francisco, CA, U.S.A.

Objective: To determine the safety and maximal tolerated dose of rCD4 and preliminary indications of antiviral effects of rCD4 in patients with AIDS & ARC.
Methods: A 2 center, phase I study with dose escalation and monitoring of the safety, pharmacokinetics, and clinical effect of rCD4 in 30 patients with AIDS or ARC.Six patients were enrolled at each dose level of 1,10,30,100, and 300 ug/kg.rCD4 was administered by a single intravenous(IV) infusion on day 1, followed by a 3 day wash out, then daily infusions for 10 days followed by a 1 week wash out, then infusions 3 times weekly for 8 weeks (11 wks total).
Results: No significant adverse effects have been noted in clinical, hematologic, or serum chemistry parameters.One patient developed borderline evidence of anti-rCD4 antibodies on day 37 that were not detected on subsequent determinations.No other instances of anti-CD4 antibody have been detected thus far. In those patients for whom follow up data is available the total T4 count was 115±95 at entry and 137±141 at 11 weeks of therapy.No individual exhibited a consistent sustained increase or decrease in total T4 count.Approximately 25% of individuals were p24 Ag(+) at entry.Follow up analysis of p24 Ag and viral isolation data are not complete.
Conclusion: IV administration of soluble rCD4 appeared to be well tolerated over the course of this study.Preliminary analysis has not indicated a significant change in total T4 count.Studies are being conducted with long term maintenance IV therapy as well as SC and IM administration.

T.B.P.304 ESSAI RANDOMISE CONTRE PLACEBO DE FORTES DOSES D'ACYCLOVIR (ACV) CHEZ LES PATIENTS HIV+

CHAVANET P.; AHO S.; MALLET J.; WALDNER A. BUISSON M. BIELEFELD P. PORTIER H. Service des Maladies Infectieuses Hopital du Bocage, BP1542, 21034 DIJON, France.

Le but de cette étude était d'étudier l'influence de fortes doses d'ACV sur la progression de la maladie HIV de patients peu ou asymptomatiques sachant que 1-les infections aigues ou latentes à virus du groupe herpes augmentent in-vitro la replication du HIV et in-vivo aggravent le pronostic la maladie HIV: 2-de fortes concentrations d'ACV ralentissent l'apparition de l'activité HIV-transcriptase inverse et la formation de syncitia de mononucleaires infectés (Resnick,1986); 3-une étude pharmacologique préliminaire de l'ACV iv 30mg/kg a assuré l'obtention de concentrations seriques et rachidiennes très importantes.
Methodes: 30 patients CDCII ou III, 21 hommes 9 femmes, agés de 17 à 40 ans, ont été randomisés en 2 groupes parallèles, et ont recu pendant 4 mois une injection par semaine associée à 1 g po de probenecid soit d'ACV 30mg/kg soit de placebo en perfusion iv de 3h.
Resultats: une infection du groupe herpes est intervenue dans chaque groupe. Les résultats sont exposés tableau 1:

	T-helper/ul		T-suppr/ul		T-h/T-s		beta2 mg/l		
	avant	apres	avant	apres	avant	apres	avant	apres	**:p=0.25
placebo	865	678*	748	792	1.25	1.07**	2.5	3.1*	*:p=0.15
ACV	747	728	848	737**	1	1.06	3.25	3.5	

*:p=0.07

Conclusions: ACV iv 30 mg/kg 1/sem, bien toléré, semble ralentir la progression de plusieurs marqueurs de la maladie HIV: baisse des T4 et augmentation des T8. Ces résultats incitent à poursuivre les études en utilisant le desciclovir. En effet cette prodrogue de l'ACV bien absorbée par voie orale donne des concentrations seriques importantes

Thérapie et évaluation clinique : toxicité des médicaments contre le SIDA

Crise d'épilepsie généralisée après l'absorption de Zidovudine à dose toxique (à propos d'une observation).

Routy J** Prajs E** Blanc A** Drony S** Moriceau M** Sarrazin C**
Hôpital Cézanne, Aix en Provence, France; Centre médical Praz, Coutant, France.

L'absorption à haute dose de Zidovudine**** a été déjà décrite chez trois patients pour des posologies comprises entre 20 et 40G soit 100 à 200 gélules en une prise (1,2,4). Les effets cliniques et hématologiques observés semblent mineurs à court et à long terme.
Nous rapportons l'observation d'un patient ayant présenté une crise d'épilepsie survenant après la prise volontaire à dose toxique de Zidovudine***.
Un patient de 35 ans, homosexuel, était traité depuis février 88 pour une tuberculose ganglionnaire à BK ; ce traitement avait été arrêté début juin en raison de sa bonne réponse. La Zidovudine avait été prescrite dès février 88 à la dose de 400mg toutes les 4 heures. Ce dernier médicament a été arrêté le 6 juin à cause d'une neutropénie ; il sera repris le 12.07 à la même dose. Le lendemain le patient absorbe délibérément 180 gélules de Zidovudine (soit 36G), 4 heures après il présente une crise d'épilepsie tonicoclonique généralisée. L'examen postcritique ne retrouve aucun signe en foyer. Le FO est normal, la PL retrouve un NA+:132 mmol/ml CL95mmol/ml Glucose:3,40 Protides:0,56g/l avec 8 hématies et 15 leucocytes/ml.
L'antigène crytococcique, le VDRL et le TPHA sont négatifs sur le LCR. La culture restera négative y compris pour le BK. Le ionogramme sanguin et la calcémie sont normaux. Le scanner et l'IRM cérébrales ne montrent aucune anomalie. L'EEG est normal. Les paramètres hématologiques hépatiques et rénaux n'ont pas été altérés, le bilan immunitaire est resté identique avant et après cette intoxication (cf tableau). Ce patient n'a pas représenté de crises analogues depuis 6 mois et n'a jamais reçu d'anticonvulsivant, son état clinique est stable.
A la lumière de notre observation devant toute crise d'épilepsie chez un patient HIV+ traité par Zidovudine une prise toxique de ce médicament doit être recherchée de principe.

T.B.P.306

Effective Doses of AZT in HIV-ITP is Associated With Erythroid Hypoplasia.

Hurlbach, L.B., Garber, G., Cameron, D.W. and Aye, M.T.
Department of Medicine, University of Ottawa and Ottawa General Hospital, Ottawa, ON, Canada

Idiopathic thrombocytopenic purpura (ITP) is not an uncommon finding in patients with HIV infection. The etiology of this thrombocytopenia remains unclear although immune complex disease has often been quoted as a contributory cause. Another possible mechanism is a defect in platelet production by HIV infected marrow cells. We report here a patient with HIV associated ITP (HIV-ITP) whose thrombocytopenia was successfully treated on three separate occasions with azidothymidine (AZT) with each remission episode being accompanied by the development of reticulocytopenia and erythroid hypoplasia. The patient, a HIV seropositive male, presented with lymphadenopathy, lymphopenia (CD4+ lymphs <0.3 x 10^9/L), thrombocytopenia (26 x 10^9/L), and a Hb of 141 Gm/L. There were no detectable platelet-associated IgG and a marrow aspirate showed adequate numbers of megakaryocytes. AZT was given at 1200 mgm/day and within 3 weeks the platelet count normalized but severe reticulocytopenic anemia developed. On discontinuing AZT, the anemia corrected but thrombocytopenia recurred. On two further occasions AZT at 600 mgm/day had no effect on the thrombocytopenia or on erythropoiesis. However, each time when the dose of AZT was increased to 1200 mgm/day thrombocytopenia remitted and anemia recurred. Due to this close association, both temporally and drug-dose related, we conclude that thrombocytopenia in this patient may have been due to HIV-associated marrow disease, with the effective dose of AZT being reflected in both the development of erythroid hypoplasia and remission of the thrombocytopenia. AZT may therefore be beneficial in HIV-ITP by alleviating peripheral platelet consumption and as well by a direct effect on the marrow.

T.B.P.307

VITAMIN B 12 SUPPLEMENTS IN PATIENTS TREATED WITH ZIDOVUDINE.

Navarette Maria-Soledad, Cherakhenian S., Cardon B., Rozenbaum W.
Infectious Disease Unit, Rothschild Hospital, Paris, France.

Objective. To evaluate the efficacy of Vitamin B12 (Vit. B12) in the prevention of Zidovudine (Z) induced anemia.
Methods. AIDS or ARC patients (pts), receiving Z were randomized in 2 groups. One group was administered weekly injections of Vit. B12 (1000 mcg) as of the first week of their treatment. Both groups received folinic acid (calcium folinate 50 mg weekly, IM). Patients under chemotherapy, or previously transfused were excluded.
Results. 49 pts, (47 m., 2 f.), mean age 36 (±7 yrs), were included. At month 4, data were available for 24 pts(table 1), who were comparable for clinical HIV-status, initial total lymphocyte and T4 count and initial hemoglobin (Hb) level. Initial and mean Z dosage regimen and number of pts treated with Trimethoprim-Sulfamethoxazole were comparable in both groups. No difference was observed in Hb levels and MCV between the group receiving Vit. B12 and that which did not (table 2). Number of dose reductions as well as interruption of Z was also comparable in the 2 groups.

Table 1

	B12+	B 12-
n	11	13
AIDS/ARC	5/6	7/6
Initial dose: 1200 mg	6	5
600 mg	5	8

[illegible]

Table 2

	Initial value		Values at Month 4	
	Hb g/dl	MCV μm³	Hb g/dl	MCV μm³
Group I (B12+) n=11	13.4	91	12.0	109
Group II (B12-) n=13	12.6	95	10.8	114

Conclusion. This study indicates that Vit. B12 at 1000 mcg/week has no role in preventing anemia, usually macrocytic, which is a serious side-effect of Zidovudine.

T.B.P.308

TOXICITY OF ZIDOVUDINE (AZT) IN PATIENTS WITH AIDS

B.Clotet,JM Gimeno,A.Jou,G.Sirera,J.Tor,M.Dominguez,M.Foz
Infectious Diseases Unit.Hospital de Badalona "Germans Trias i Pujol",Barcelona,Catalonia,Spain.

Objective:To report the hematologic toxicity observed in 32 AIDS patients treated with zidovudine for a 3 month period.
Material:Thirty-two AIDS patients,fulfilling the CDC criteria for AIDS,received AZT at a dosage regim of 1200 mg/d.Hematologic evaluation was done each month or when symptoms appeared.All patients received concomitantly therapy with folinic acid (15 mg/d.) and B12 (100 ug/i.m./15d.).
Results:A hemoglobin reduction below normal or precedent values were observed in 15 patients (47%).Five patients (15%) had a reduction in hemoglobin level below 7.5 g/dl and were given red-cell transfusion.Neutropenia occurred in 17 cases (55%) being only below 700 per cubic millimeter in 3 (10%).Lymphopenia was present in 16 (50%).Platelet counts increased in many patients (64%) and only in 2 cases the numbers fell more than 50% from the base line.A table showing all results would be presented.
Discussion:In spite of supplying B12 and folinic acid we have observed hematologic toxicity in a high percentage of patients.The hematological toxicity led to interruption or reduction of the dosage in many patients.For severely affected AIDS patients initial treatment with low doses of AZT (600-800 mg/d.) should be assayed for demonstrating if such doses,associated with suppressive treatments for opportunistic infections,are as effective as the previous regims and may prolong the benefits related to AZT.Also it should be evaluated if increase of B12 dose diminishes the hematological untoward effects.

T.B.P.309

CORTICOTHERAPIE PROLONGEE D'UNE DERMATOPOLYMYOSITE A V.I.H.

René René*; Debord T.*; Dormont D.**; Vaseux R.***; Tiane B.*
* Hôpital Militaire Bégin, 94160, Saint-Mandé;
** CEA - CRSSA , 92265, Fontenay aux Roses;
*** Institut Pasteur, Paris, FRANCE.

Objectif: L'intérêt et l'innocuité des corticostéroïdes à dose élevée et en cure courte chez les SIDA ayant déjà été démontrés, l'objectif est de décrire l'absence d'effet immunosuppresseur d'une corticothérapie au long cours lors de l'infection à VIH.
Méthode: observation d'un antillais de 22 ans ayant reçu de la prednisolone entre 20 et 40 mg par jour pendant 4 ans et demi pour une dermatopolymyosite grave, révélée en 1983 en même temps qu'une hépatite virale aiguë B associée à de la fièvre, des polyadénopathies cervicales et axillaires; le VIH 1 a été retrouvé dans un ganglion mais pas dans le muscle. Plus tard, les anticorps anti VIH 1 ont été détectés en Western-blot.
Résultats: L'hépatite B a guéri simplement. La dermatopolymyosite a totalement régressé sans insuffisance surrénale ni rechute à l'arrêt du traitement; le recul est de un an. Le patient est resté dans le groupe III de la classification CDC/OMS. Le taux de CD4+ a évolué entre 128/mm3 (1984) et 922/mm3 (1987). La bêta 2 microglobulinémie est restée à des taux voisins de 3 mg/l. L'antigène P25 est toujours resté négatif. Deux cultures de lymphocytes circulants, en janvier et en juin 1988, produisent du VIH 1.
Conclusion: Une corticothérapie de plus de 4 ans a guéri une dermatopolymyosite à VIH 1 (étiologie rare), groupe III, sans précipiter l'aggravation de l'immunodépression ni l'évolution vers le SIDA.

T.B.P.310

SUCCESSFUL RE-INTRODUCTION OF ZIDOVUDINE (AZT) AFTER AN ALLERGIC CUTANEOUS REACTION TO AZT.

Anne Mathieu-Boué, P. Halfon, P. Lebras and R. Caquet
CISIH, Paris Sud, France.

Allergic cutaneous reactions to AZT are uncommon and usually lead to definitive withdrawal of this drug. We report here a case of successful re-introduction schedule.

A HIV seropositive 29 year old male (heterosexual exposure) with an oral hairy leucoplakia had two relapses of subacute febrile meningitis unexplained by secondary pathogens or neoplasms. p24 was negative in blood and > 1000 pg in CSF. AZT was started (200 mg x 6 p.o/day) in January 1988.

After 14 days, a difuse pruriginous erythematous skin rash and periorbital oedema appeared. AZT was discontinued and cutaneous lesions disappeared within 24 H. The lesions can reasonably be ascribed to AZT for the following reasons : a) the plaques appeared after 14 days of treatment and no other drug was taken simultaneously. b) there was no previous history of skin rash. c) lesions disappeared rapidly when AZT was withdrawn. d) Human basophil degranulation test (HBDT) was positive with AZT. A third relapse of meningitis with radiculoneuritis induced us to re-introduce AZT by means of a schedule of gradually increasing doses per os : 100 ml x 3/day for 3 days ; the dose was increased by 100 mg/day until 1 200 mg/day. No adverse reaction was noted. Two months later HBDT became negative. In January 1989 no relapse of meningoradiculoneuritis occured and AZT therapy is well tolerated.

This observation shows that cautious reintroduction of AZT can be proposed for sensitive patients. However more experience with this regimen will be required before it is generally accepted.

T.B.P.311 ROLE OF P24 AG TESTING IN PATIENTS ON ZIDOVUDINE

Hoy,Jennifer.;Chua,J.; Mijch,A.; Dimitrakakis,M.; Gust I.,Lucas,C.R.
Fairfield Infectious Diseases Hosp., Melbourne,Victoria, Australia.

Objective. To examine the role of regular measurement of serum p24 antigen (ag) in the management of HIV infected patients (pts) on zidovudine (AZT).
Methods. From 1 June 1987, 95 pts (59 AIDS, and 36 ARC) have received AZT for 6-18 months, reviewed 2-4 weekly, and had monthly serum p24 ag estimations, measured by a solid phase sandwich immunoassay (Abbott Laboratories).
Results. At entry, there were 39 p24 ag positive (+ve) pts (25 AIDS, 14 ARC) and 56 p24 ag negative (-ve) pts (34 AIDS, 22 ARC). The follow-up period was a mean 56.1+18.7 weeks for p24 ag+ve pts, and 54.8+13.3 weeks for p24 ag-ve pts. Twelve p24 ag+ve pts became p24 ag-ve on AZT, while 27 remained p24 ag+ve. Twenty-five p24 ag-ve pts became +ve on AZT while 31 remained p24 ag-ve. There were 17 deaths and no significant difference in mortality between p24 ag+ve and p24 ag-ve pts. Thirty-three of the 39 p24 ag+ve pts developed further opportunistic infections (OI) (22 AIDS, 11 ARC) while 39 of the 56 p24 ag-ve pts had a further OI (23 AIDS, 16 ARC). There were significantly less OI in the p24 ag-ve group for AZT treatment periods up to 12 months. After 12 months there is no difference in OI between p24 ag+ve and p24 ag-ve patients. Eleven p24 ag+ve (6 AIDS, 5 ARC) and 20 p24 ag-ve (15 AIDS, 5 ARC) tolerated full dose AZT (>1000mg/day). Eight of the 11 p24 ag+ve and 8 of the 20 p24 ag-ve pts developed further OI. On reduced dose AZT due to toxicity, 25of 28 p24 ag+ve and 31 of 36 p24 ag-ve pts developed further OI. Eighteen of the initially p24 ag-ve pts became p24 ag+ve on full dose AZT.
Conclusion. The presence of serum p24 ag may predict outcome in patients treated with AZT for less than 12 months. Neither the predictive value of p24 ag nor the benefits of AZT persist beyond 12 months.

T.B.P.312 CHANGE IN BETA-2 MICROGLOBULIN (B2M) DURING ZIDOVUDINE (ZDV) THERAPY (RX) PREDICTS CLINICAL OUTCOME

Jacobson, Mark A*, Abrams, D*, Bacchetti, P*, Kocurek, K*, Wilber, J**, Moss AR*, et al***. *UCSF, SF General Hospital and **SF Public Health Dept., San Francisco, CA; ***Immunodiagnostic Laboratory Inc., San Leandro, CA and AIDS Clinical Trials Group, NIAID, Bethesda, MD. USA.

Objective. Determine if changes during ZDV Rx in CD4 lymphocyte number or any of 4 serologic markers of HIV activity predict clinical outcome.
Methods. Whole blood CD4 lymphocytes (CD4) and serum p24 antigen (p24 Ag), beta-2 microglobulin (B2M), neopterin (NPT) and p24 antibody (p24 Ab) were measured pre-Rx and serially during ZDV Rx in 39 AIDS and ARC patients (pts). We examined the association between change from baseline value of these markers during the first 8-12 weeks (wks) of ZDV Rx and clinical outcome 14-18 months (mos) after ZDV Rx was initiated.
Results. Among pts whose serum B2M *increased* during the first 8-12 wks of ZDV Rx, 9/11 had 1 or more serious events (SE) occur (death, life-threatening opportunistic infection, lymphoma) during 14-18 mos of follow-up; while among those whose B2M decreased, 10/28 had SE (p=.01, odds ratio [OR]=10.0). Neither increase in p24 Ag nor NPT, nor decrease in CD4 nor p24 Ab predicted SE (OR=.9-1.5). When controlled for underlying diagnosis (AIDS vs. ARC), B2M increase was still predictive of SE by bivariate logistic regression analysis (p=.02). Also, among pts whose B2M was in the normal range at wk 8 of ZDV Rx, 0/11 were moribund (Karnofsky performance status $\leq$ 60) or dead at 14-18 mos compared with 16/28 whose wk 8 B2M was elevated (p=.001).
Conclusion. Decrease or normalization in B2M during the first 8-12 wks of ZDV Rx was predictive of stable clinical status 14-18 mos after starting ZDV.

T.B.P.313 USE OF MULTIPARAMETRIC FLOW CYTOMETRY (LYMPHOCYTE P24-FCA) TO EVALUATE AZIDOTHYMIDINE THERAPY

Ohlsson-Wilhelm, Betsy M.*; Cory, J.M.*; Kessler, H. A.**; Eyster, M. E.*; Rapp, F.*; Landay, A.**, et al.
*M. S. Hershey Medical Center, The Pennsylvania State Univ., Hershey, PA;
**Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL, USA.

Objective. To evaluate in a cross-sectional study the effect of azidothymidine (AZT) treatment on levels of active HIV-1 infection in AIDS patients.
Methods. A new test, lymphocyte p24-FCA, based on multiparametric flow cytometry, was used to quantitate active HIV-1 infection of peripheral blood lymphocytes in <24h. Results were expressed as % p24 positive cells. The assay is based on binding of monoclonal antibody specific for p24 core protein; therefore, only cells with actively replicating HIV were detected. Viral isolation was by standard coculture methods. Other work has shown a correlation between viral culture positivity and samples with >1.0% positive lymphocytes.
Results. AIDS patients receiving AZT were compared to untreated AIDS patients using lymphocyte p24-FCA. Patients receiving AZT had a mean lymphocyte p24-FCA of 0.3% (n=26)(range <0.1-0.7) whereas untreated patients had values of 0.3, 1.7 and 16.4% (mean = 6.1%). One patient for whom treatment was discontinued increased from 0.1% to 0.9% in < one month.
Conclusion. Use of a rapid, quantitative test confirmed reduction of active HIV-infection by AZT in a small study. Lymphocyte p24-FCA should be considered for new studies evaluating antiretroviral agents.
(Supported by USA NIH HLBI, NO1-HB-67023 Project #221924 and AI25915).

T.B.P.314 The inhibitory effects of AZT on HIV replication as determined by p24 antigen capture assays

M.V. O'Shaughnessy[1], D. Lepine[1], M. Wainberg[2], J. Ruedy[3], C. Tsoukas[2], M. Fanning[4], J. Montaner[3] and K. Gelmon[3]
1 - Federal Centre for AIDS, Ottawa, 2 - McGill University, Montreal,
3 - St. Paul's Hospital, Vancouver and 4 - University of Toronto, Toronto, Canada

A Canadian multicenter study assessed the possible toxic effects of AZT (Zidovudine) in 72 HIV-1 infected individuals. In this dose-escalating study, the patients were initially treated with 600 mg of drug/day for 18 weeks, 900 mg/day for another 9 weeks and 1200 mg/day for another 9 weeks. A "washout" period of 6 weeks followed after which the drug was restarted at 1200 mg/day. During this study, both the levels of HIV p24 antigen detected by two commercial kits and the recovery of HIV-1 from cultured peripheral blood lymphocytes were measured. Twenty-two patients were HIV-1 p24 antigen positive during the study. Treatment with AZT even at the 600 mg/day regimen reduced the levels of circulating p24. In patients that were p24 antigen positive upon entry, treatment with the drug resulted in a sharp decrease in the levels of antigen which persisted for the treatment duration. During the 6 week washout the levels of p24 antigen rose. Drug was reinstituted at 42 weeks and the patients are being monitored to assess the effect of the washout/reinstitution on HIV p24. In those patients in which the level of p24 antigen rose during AZT treatment, there was an accompanying alteration in their antibody profile. The level of antibody to p24 relative to that of gp41 decreased as the p24 antigen increased. There was agreement between these observations and worsening physical condition.

T.B.P.315 THE EFFECT OF TREATMENT WITH ZIDOVUDINE ON IMMUNE SYSTEM DEFECTS EARLY IN THE COURSE OF HIV INFECTION

Reiter, William M; Cimoch, PJ; Center for Special Immunology,
Ft. Lauderdale, FL, USA.

Objective. To study the immune system effects and toxicity of zidovudine in patients with HIV infection and T4 lymphocyte counts between 200 and 400 cells/cu mm.
Methods. Patients were further evaluated by determination of HIV p24 antigen level, lymphocyte blastogenesis response to stimulation with the mitogen PHA, beta-2 microglobulin level, CBC, chemistries and zidovudine levels. Therapy was initiated with zidovudine, 200mgs q4H if HIV p24 antigen was detected, or 200mgs q6H if antigen was not detected. Laboratory studies were obtained every 3 months. Results in these patients were compared with patients who initially presented with T4 lymphocyte counts below 200 cell/cu mm. No other anti-viral medications were administered.
Results. 38 patients were in the early treatment group. T4 mean was 285 cells/cu mm baseline, 388 at 3M and 405 at 6M. Stimulation index with PHA mean was 34 baseline, 97 at 3M and 76 at 6M. HIV p24 antigen mean was 132 pg/ml baseline, 46 at 3M and 56 at 6M. Hct mean was 42.2% baseline, 39.0 at 3M and 40.7 at 6M, 1 patient received a transfusion. There were 28 patients in the late treatment group. T4 mean was 97 baseline, 136 at 3M and 98 at 6M. Stimulation index mean was 25 baseline, 53 at 3M and 51 at 6M. HIV p24 antigen mean was 121 baseline, 97 at 3M and 117 at 6M. Hct mean was 37.5 baseline, 34.7 at 3M and 37.8 at 6M, 9 patients received transfusions.
Conclusion. Earlier treatment of HIV infection, before advanced damage to the immune system occured, resulted in improvement of the immune system defects studied without the development of clinical disease or significant toxicity. Patients for whom therapy was initiated later in the course of HIV infection did not show this improvement. Earlier initiation of anti-viral therapy with zidovudine may halt the progressive immune destruction and improve defects in immune function in patients with HIV infection.

T.B.P.316 CUTANEOUS REACTIONS TO TRIMETHOPRIME-SULFAMETHOXAZOLE (TMP-SMZ) IN THE TREATMENT OF PNEUMOCYSTIS CARINI PNEUMONIA (PCP)

Schoefer,Helmut*;Ochsendorf,FR*.;Bauer,H.*;Milbradt,R.*and Stille W.**.
Klinikum der J.W.Goethe Universität,*Dept.of Dermatology,**Centers of Internal Medicine,Frankfurt,FRG.

Objective. To evaluate the prevalence, clinical morphology and course of cutaneous reactions to TMP-SMZ in the treatment of HIV-associated PCP.
Methods. Prospective clinical and morphological examination for untoward skin reactions in the treatment of 76 consecutive episodes of PCP in 61 patients (51 first manifestations), 25 relapses) with TMP (20 mg/kg) -SMZ (100mg/kg) per day.
Results.Patients with first PCP-episodes (group I) showed cutaneous rashes in 23% (12/51). Patients with recurrent PCP (group II) and the same therapy regimen in 56 % (14/25). Cutaneous eruptions (exanthema) occurred 10,7 days after the onset of therapy in group I and remarkably earlier (mean 7,5 days) in group II. In typical cases there was a non itching erythema, beginning in the patients face, extending in craniocaudal direction 2-4 days prior to exanthema.
In 77% exanthema consisted of disseminated small red macules with confluence and pruritus. 3 patients developed a maculopapular, 2 an urticarial exanthema and another 2 erythema multiforme (in 1 patient with progression to Stevens-Johnson syndrome).
TMP-SMZ therapy had to be stopped in 11/26 patients with cutaneous reactions.
Conclusions.Cutaneous eruptions in the treatment of PCP with TMP-SMZ are very frequent but not homogeneous. Besides probably toxic reactions (facial and truncal erythema) we observed urticarial, maculopapular eruptions and severe erythema multiforme. Simple erythema does not force to stop therapy when high doses of antihistamines are given. However, when mucosal lesions occur (Stevens-Johnson-syndrome, toxic epidermal necrolysis) TMP-SMZ therapy has to be stopped.

T.B.P.317

PRELIMINARY OBSERVATIONS ABOUT THE ADVERSE EFFECTS OF PEFLOXACIN IN THE TREATMENT OF SALMONELLA BACTEREMIA IN PATIENTS WITH AIDS

Levi, Guido Carlos; Medeiros, E.A.S.; Mendonça, J.S. de; Carvalho, M.C.S. de; Stefani, H.A.V; Pinczowski, H.
Serviço de Moléstias Infecciosas, Hospital do Servidor Público Estadual - São Paulo, Brasil.

We treated 3 patients with AIDS and positive blood cultures for *Salmonella* sp; in 2 cases *S.typhimurium* and, in one, *S.dublin*. They received pefloxacin orally, 800 mg/day, in 2 divided doses. They had a fast clinical and microbiological response, with disappearance of fever in few days and negativation of the blood cultures. Unfortunatelly, they also developed severe side effects. One patient developed Stevens-Johnson syndrome on the third day of treatment, one presented pruritous generalized maculo-papular rash on the fourth day, and the third had to interrupt treatment on the fifteenth day due do severe headache and insomnia. All side-effects reversed soon after stopping pefloxacin.

These preliminary observations suggest that the new quinolones may cause in AIDS patients, as also describe before with other drugs, increased and more severe adverse effects, and calls our attention to the necessity of extreme prudence in further studies with their use in patients with HIV infections.

T.B.P.318

SEVERE, ACUTE TRIMETHOPRIM-SULFAMETHOXAZOLE (T-S) REACTION MIMICS SEPSIS IN AIDS PATIENTS

Johnson, Michael P.*; Goodwin, S.D.**; Shands, Jr., J.W.*
Colleges of Medicine* and Pharmacy**; University of Florida; Gainesville, Florida, USA.

Objective. To describe a severe, acute syndrome of fever, hypotension, and pulmonary infiltrates in HIV infected patients receiving T-S.

Methods. We present the cases of two patients that we have seen and the four cases reported in the literature to describe this new syndrome.

Results. The clinical features occurred within hours of T-S therapy.

Patient	Fever	Rash	Hypotension	Chest X-ray	Pneumocystis	Prior T-S
1	39	Yes	75 mm/Hg	New Infiltrate	Not Detected By Bronchoscopy	Unknown
2	39	Yes	65 mm/Hg	New Infiltrate	Not Detected By Bronchoscopy	Unknown
+ 3	40	Yes	60 mm/Hg	New Infiltrate	Previously Treated	Yes
+ 4	40	Yes	70 mm/Hg	New Infiltrate	Previously Treated	Yes
+ 5	40	Yes	"low"	Not Described	Previously Treated	Yes
+ 6	41	Yes	60 mm/Hg	New Infiltrate	Previously Treated	Yes

All patients improved following discontinuation of T-S.

Conclusion. An unusual syndrome of high fever, hypotension, and pulmonary infiltrates may follow T-S administration to HIV infected individuals with proven or suspected Pneumocystis carinii pneumonia. This syndrome, unreported in non-HIV infected patients and rare in HIV positive patients, is acute, severe, and may be difficult to distinguish from sepsis.

+ Case reports obtained by literature search.

T.B.P.319

HYPOGLYCEMIE ET DIABETE DUS AU MESYLATE DE PENTAMIDINE AU COURS DU SIDA.

Perronne, Christian*; Bricaire F.*; Leport C.*; Vildé J.L.*; Assan D.**; Assan R.**.
Hôpitaux *Claude-Bernard - **Bichat, 75018 Paris, France.

Objectif: Analyser la glycémie de 18 SIDA (pneumocystoses) traitées par mésylate de pentamidine (P), 4 mg/kg/j en i.v.

Méthodes : Des glycémies (hors perfusion) ≤ 3,2 mmol/l définissaient l'hypoglycémie et > 10 mmol/l le diabète.

Résultats : 8 malades ont eu un trouble glucidique : 4 des hypoglycémies, 3 des hypoglycémies puis un diabète et 1 un diabète d'emblée (39% d'hypoglycémies, 22% de diabète). Les hypoglycémies (=2,1±0,7 mmol/l) étaient précoces (5±1 jours après le début de P) avec 2 comas prolongés. Le diabète (glycémie=26,5±8,2 mmol/l) survenu après 41±14 jours, était insulinodépendant chez tous. La dose totale de P était 1941±218 mg en cas de trouble vs 1170±152 mg en leur absence. La créatininémie sous P était 194±15 µmol/l (hypoglycémie + diabète) 236±62 µmol/l (hypoglycémie seule), vs 118±14 µmol/l (absence de trouble) : p < 0,01.

Conclusion: Doses élevées et insuffisance rénale favorisent l'accumulation de P et les troubles glucidiques. Avec le mésylate, la fréquence des hypoglycémies (39%) et surtout du diabète (22%) est supérieure qu'avec l'isothionate de P (27% d'hypoglycémies, 0% de diabète : *Stahl-Bayliss C.M. et al. Clin Pharmacol Ther, 1986, 39, 271-5*).

T.B.P.320

ORAL DESENSITIZATION TO SULFADIAZINE AND TRIMETHOPRIM-SULFAMETHOXAZOLE (TMP-SMZ) IN 4 PATIENTS WITH ACQUIRED IMMUNODEFICIENCY SYNDROME

Moreno, Jose N.*; and Maggio, CM**. University of Miami School of Medicine, Miami*, Florida, USA. Jackson Memorial Hospital**, Pharmacy Department, Miami, Florida USA.

Objective. To develop and evaluate an abbreviated oral desensitization program for patients with AIDS allergic to sulfadiazine and/or TMP-SMZ.

Methods. Four patients with prior allergic reactions to sulfadiazine (3) and TMP-SMZ (1) were identified. Allergic reactions included a severe generalized erythematous rash with pruritus. Sulfadiazine oral suspension was compounded at a concentration of 1 mg/ml. An initial dose of 1 ml was given and subsequent dose concentrations were doubled every 15 minutes to achieve a total dose of 1 gm within 2.5 hours. TMP-SMZ suspension, serially diluted to 10 mg/ml (SMZ compound), was administered in aliquots of 1/2, 1, 2 and 4 ml every 15 minutes to achieve a total dose of approximately 800mg of SMZ after 9 hours.

Results. One patient had mild rash and pruritus at 400 mcg of SMZ component. Desensitization was interrupted for 48 hours and restarted with successful completion. With long-term followup, one patient has demonstrated a photosensitivity-like reaction and sulfadiazine was discontinued temporarily.

Conclusions. Oral sulfadiazine and TMP-SMZ desensitization should be considered in patients with sulfonamide-allergy. Compared to current literature values, an abbreviated desensitization program, as described, may be useful.

T.B.P.321

A METHOD FOR RAPID ORAL DESENSITIZATION OF PATIENTS ALLERGIC TO AZT

MacFadden, D.K. Toronto Western Hospital, University of Toronto, Toronto, Ontario, Canada.

Patients with HIV infection experience an increased frequency of allergic reactions to antimicrobial drugs with approximately 1% experiencing a sufficiently severe reaction to AZT to warrant discontinuation of the drug. In a population of 200 patients treated with AZT, 3 patients with no prior history of any sensitivity developed a severe maculo-papular rash within 8-12 days of the start of therapy requiring drug withdrawal. Two subsequent re-challenges were attempted in 1 patient and resulted in reappearance of the rash at 12 and 2 hours respectively.

Method: In an attempt to desensitize 3 patients, AZT was given orally in increasing doses according to the following schedule: 1, 10, 20, 50, 100, 200 and 500 µg every 15 minutes; 1, 2, 5, 10, 20, 50 mg hourly and 200 mg every 4 hours thereafter.

Results: All 3 patients tolerated AZT desensitization without adverse clinical, hematological or immunologic effects. One patient underwent 2 successful desensitizations following AZT withdrawal for intercurrent illness.

Conclusion: Intolerance to AZT resulting in severe rash can be treated with a simple, rapid oral desensitization. Repeated desensitizations may be performed with little risk of adverse reactions.

T.B.P.322

RECOMBINANT INTERFERON β_{ser} PROTECTS AGAINST ZIDOVUDINE-INDUCED GENETIC DAMAGE IN AIDS PATIENTS.

Shafik, Hasnaa*; Nokta, M.** and Pollard, R.B.
*Department of Community, Environmental and Occupational Medicine, University of Ain Shams, Cairo, Egypt; and **Department of Internal Medicine, The University of Texas Medical Branch, Galveston, Texas, USA.

This study was conducted to evaluate the in vivo geno-toxicity of zidovudine (ZDV) in patients with AIDS. AIDS patients that were non-smokers and on ZDV (1200 mg/day) as a sole medication for 4 weeks to 7 months were recruited in the study. AIDS and ARC patients prior to receiving any therapy served as a negative control. Whole blood cultures were initiated by conventional methods with PHA 1:50 dilution. For each study subject each experiment consisted of an untreated control and recombinant interferon-β (rIFN-β) experimental group. Experimental group cultures received 10, 100, 1000, 10,000 units of rIFN-β for the entire incubation period. Cells were harvested at 72 hours and stained with the fluorescense plus Giemsa method which enables the determination of number of division cycles a cell has completed. One hundred metaphases from first division cells were scored from each culture for chromosome aberrations that were mainly from the chromatid-type, i.e. chromatid, chromosome, and isochromatid breaks. The frequency of breaks in the study and negative control group was 5.14 ± 1.14 and 0.5 ± 0.29 per 100 cells respectively ($p<.05$). Cultures receiving 100 and 1000 units of rIFN-β, however, showed a frequency of 2.15 ± .3 and .57 ± .57 respectively, which was significantly lower than the untreated cultures ($p<.005$), using paired t-test. At the highest dose of rIFN-β no aberrations were detected. We conclude that rIFN-β protects against ZDV induced genetic damage.

T.B.P.323 MEGALOBLASTIC CHANGES IN THE BONE MARROW OF AZT TREATED AIDS-PATIENTS AS A PROGNOSTIC MARKER FOR NEED OF BLOOD TRANSFUSION.

Buys, Leendert; Van Den Berg-Wolf M, Pieterse R, Ten Veen J, Reesink H.
Vereeniging voor Ziekenverpleging Prinsengracht,
Amsterdam, The Netherlands.

Objective: to study the effects of one year azidothymidine (AZT) treatment on the erythropoiesis of AIDS-patients.

Patients and methods: twenty three male patients, classified as having AIDS underwent serial bone marrow aspirations during AZT treatment (6 x 200 mg daily).

Results: After one month AZT 12/23 (52%) of the patients exhibited moderate megaloblastic changes in the bone marrow, whereas the other 11 remained normoblastic. Sixteen patients were available for follow up after 12 months AZT therapy, 8 from the megaloblastic group and 8 from the normoblastic. Vitamin B12 and folic acid levels were not significantly different in both groups during AZT treatment. In the group with megaloblastic changes the patients needed a significantly higher number of red cell concentrates than in the normoblastic group, i.e. 42 units versus 6 units ($p < 0.05$).

Conclusion: Megaloblastosis of the bone marrow early in the treatment with AZT may be a prognostic marker for the need of blood tranfusion in AIDS-patients.

T.B.P.325 HOME TRANSFUSION FOR AIDS PATIENTS ON ZIDOVUDINE

Mary Busalacchi *, K Ivantic *, I Gilson **
*Visiting Nurse Association, Milwaukee, WI, USA, **Department of Medicine, University of Wisconsin Medical School (Milwaukee Clinical Campus), Milwaukee, WI, USA

Objective. To describe a home blood transfusion (HT) program for AIDS patients (pts) on zidovudine (ZDV) therapy
Methods. AIDS pts with ZDV-related anemia (Hgb < 8 gm%) were administered HT by home care nurses as an alternative to hospital transfusions (tx), usually as 2 units of WBC-poor packed RBC, under supervision of the primary MD. Most pts were ambulatory and all were hemodynamically stable. All were required to have a companion present after HT.
Results. 8 AIDS pts on ZDV were given 170 u WBC-poor packed RBC over mean 13 mo (range 2-18). 128 u were HT and 42 u were hospital outpatient or inpatient tx. 6 pts are presently alive (5 still on ZDV), 2 expired from opportunistic infections. One pt had an urticarial reaction to HT which responded to antihistamine, one pt had a delayed hemolytic reaction to blood given as an inpatient, several minor febrile reactions to HT did not require treatment. Cost for 2 units HT = $342, cost for 2 units in hospital = $ 609. HT reduced total tx cost by 31%, saving an average of $1964/pt/yr. No pt has had to permanently stop ZDV because of anemia, and all pts continue to prefer HT.
Conclusion. HT is feasible, safe, cost-effective, and facilitates long-term ZDV therapy in the home environment.

T.B.P.327 POLYMYOSITIS DURING ZIDOVUDINE THERAPY

Sharpton, Thomas, Kaiser Foundation Hospital, Oakland, California, USA.

Objective. To determine the incidence of polymyositis during zidovudine(AZT) therapy
Methods. A 12 month prospective followup of a cohort of 20 patients(pts) taking AZT. Creatine phosphokinase (CPK) was routinely monitored during visits and in pts with symptoms of polymyositis.
Results. Eight pts (40%) were found to have elevated CPK over the period of observation. Onset of lab abnormality was from 10 days to 17 months (mean 7.8 months) after starting AZT. Most pts had mild Quadriceps muscle weakness and fatigue on exertion; 1 pt had acute onset Quadriceps tenderness and weakness which resolved in 1 week; 1 pt had chronic weakness limiting ability to ambulate. Myositis either resolved (4pts) or remained stable (4pts) despite continued AZT in all patients from 3 to 13 months (mean 4.6) after onset of polymyositis. Peak CPK ranged from 418 to 8941 IU/l (nl 0-200); duration of elevation varied from 1 to 5 months. No correlation between dose of AZT and severity of polymyositis was found.
Conclusion. Mild polymyositis is common during zidovudine therapy but usually resolves or remains stable during continued zidovudine therapy.

T.B.P.324 THE EFFECTS OF PCP PROPHYLACTIC AGENTS ON ZIDOVUDINE-INDUCED ANEMIAS

Rodgers, P.; Craig Keyes; Marte, C.; Wolbert, J.; Kelly,J; Ribble, D.; Bellevue Hospital Center/ Community Health Project, NY, NY, USA.

Objective: To review transfusion requirements in PCP prophylaxed patients receiving Zidovudine. Method: Through chart review, transfusion requirements for 169 patients on Zidovudine therapy for a median of 22 weeks were compared by type or absence of PCP prophylaxis. Eighty-eight patients received TMP/Sulfa, 59 patients received aerosolized Pentamidine and 22 patients received no PCP prophylaxis. Hematocrits (Hct) were recorded at onset of Zidovudine therapy and at time of transfusion. Length of time from initiation of Zidovudine to time of transfusion was recorded. Results: 34 patients required transfusion: 28 (32%) on TMX/Sulfa, 10 (17%) on aerosolized Pentamidine and 11 (50%) without prophylaxis. The TMX/Sulfa and Pentamidine groups were not statistically different with respect to pre-Zidovudine Hct or time to transfusion. However, in the non-prophylaxed group the pre-Zidovudine Hct was significantly lower (31.7% vs. 36.85%, p less than .01) and the onset of transfusion-dependent anemia significantly sooner (82 days vs. 103 days, p less than .01). Conclusion: The use of TMX/Sulfa as a PCP prophylactic agent as compared to aerosolized Pentamidine is associated with a significant increase in the incidence of transfusion-dependent anemias. Randomized, controlled studies are indicated.

T.B.P.326 THE TOXICITY OF ZIDOVUDINE IN THE TREATMENT OF PATIENTS WITH AIDS-RELATED COMPLEX (ARC) AND AIDS

Stambuk, Drago; Mir, N.; Hawkins, D.; Costello, C.; Gazzard, B. St. Stephen's Hospital, London, England.

Objective. To evaluate zidovudine toxicity over a two year period of its clinical use in HIV patients.
Methods. Zidovudine-treated 351 ARC and AIDS patients, on 200mg 4-hourly oral regimen, have been monitored fortnightly for up to two years.
Results. Over a median follow-up of 8.5 months (range 1 - 23) zidovudine was stopped/discontinued because of death (51), drug toxicity (48), other toxic treatments (23) or patient's request (27). The dose was lowered in 50 patients due to toxicity. Anaemia or pancytopenia accounted for drug cessation and lowering of dose in 74 and leucopenia alone in 16 cases. Of 15 patients with thrombocytopenia, the platelets rose to normal level in 11 but this was not sustained for longer than 5 months in 5 patients. 192 (26%) subjects received at least one blood transfusion. Of 110 patients who were on zidovudine for more than one year in 66 (60%) drug had been discontinued. Bone marrow aspirate in 13 patients with median follow-up of 8 months showed hypocellularity in 6 and hypocellular erythropoiesis in 8 patients. In 8 patients with a 3-fold rise in CPK, zidovudine was stopped in a median follow-up of 11 months; in 4 the levels didn't change significantly, in 2 fell substantially and in 2 normalised. Muscle biopsy in 7 of these 8 patients, with also associated peripheral muscle aching, was normal.
Conclusions. Zidovudine treatment in ARC and AIDS patients causes severe haematological toxicity and possibly affects muscle metabolism. By one year 60% of treated patients needed to be taken off zidovudine.

T.B.P.328 EOSINOPHILIA IN HIV INFECTED PATIENTS UNDER ZIDOVUDINE THERAPY.

Dejace, Pierre ; Morgan, JE; O'Neil, CE; Valainis G; and Hyslop, NE. Tulane University, New Orleans, LA, USA.

Objective. To evaluate eosinophilia in patients with symptomatic HIV infection before and during Zidovudine (ZDV) therapy.
Methods. Forty nine individuals with late ARC or AIDS who had negative stools for parasites were studied. The natural history of eosinophilia, and absolute numbers of neutrophils and lymphocytes, could be followed in 47 of them during ZDV treatment. Eosinophil (EOS) percentages (%) were from the differential; absolute EOS count was derived from that value and the WBC. Geographic controls established the normal range.
Results. Twenty two individuals (45%) had raised EOS % (> 4%). Absolute EOS counts (> 450) were elevated in 9/49 (18%) subjects. Following treatment with ZDV (median duration = 22 weeks, span 2 - 24), 38% had raised % and 9% had elevated absolute EOS count. For the entire population, there were significant reductions in EOS %, numbers, and total lymphocyte numbers ($p < 0.05$). Overall, neutrophils were unchanged. In a subset of patients ($n=16$) with neutrophil toxicity (mean time of appearance = 5.9 ± 1.3 weeks), both EOS % and absolute count decreased. When dose reduction of ZDV resulted in a raise in neutrophil numbers there was a concomitant increase in both % and absolute EOS count.
Conclusion. Increased EOS % seen in symptomatic HIV infected patients are frequent and are associated with elevated absolute counts. Thus, there appears to be a true rise in EOS % in many HIV-infected patients. When ZDV treatment induces neutrophil toxicity, EOS are usually reduced also, suggesting that ZDV can be toxic for EOS, as well as neutrophils.

T.B.P.329

AZT: DOUBLE EDGED SWORD

Pivar, Ilona; Temoshok, L.; University of California School of Medicine, San Francisco, CA., U.S.A.

Objective. To provide information about patients' stressors as well as positive perceptions regarding AZT that may influence their decision to take AZT, cooperate with treatment, and possibly their treatment outcome.
Methods. 103 seropositive homosexual men with at least one HIV-related symptom were recruited *from the UCSF AIDS Clinic* and administered an in-depth, semi-structured interview at 3 time points approximately 6 months apart. The interview was designed to elicit stressors, coping strategies, and both positive and negative perceptions in such areas as HIV testing, symptom recognition, clinical diagnosis, illness episodes, and treatments.
Results. 55 Ss spontaneously raised 39 concerns about AZT and 26 positive perceptions. The numbers of Ss who mentioned these concerns, which we categorized, were: 38--toxicity side-effects; 20--cost and financing; 18--facing decisions about beginning treatment, dosage, and choosing the right drug; 18--AZT as a negative symbol of the reality of ARC/AIDS; 11--negative or unsatisfactory interactions with health care providers, 10--lifestyle disturbances; 9--effectiveness of AZT; 7--drug study protocols; 7--lack of funding/availability of drugs; 6--telling others; 5--going off AZT; 4--time limitations; 4--availability of social support; 2--peer pressure to choose AZT; 2--peer pressure to choose an alternative. By the Time 2 interview, 30 Ss had been on AZT at some point, in addition to 4 on study protocols. A total of 22 subjects experienced negative side effects they attributed to AZT.
Conclusion. For some AIDS and ARC patients, AZT has been a means of prolonging survival and reducing the severity and frequency of opportunistic infections. For many of the ARC patients in our study, however, AZT also involved a number of physical and psychosocial stressors.

T.B.P.331

PHASE I STUDY OF INTERFERON ALPHA-2b (INTRON), ZIDOVUDINE AND rGM-CSF IN PATIENTS WITH AIDS-ASSOCIATED KAPOSI'S SARCOMA

Fischl, Margaret; Uttamchandani, R; Gagnon, S; Thompson, L; and Santiago, S. University of Miami, Miami, Florida, USA.

Objective. To evaluate the efficacy and safety of *r*GM-CSF in combination with Intron and zidovudine in patients with AIDS-associated Kaposi's sarcoma (KS).
Methods. Patients with KS and no active infections were enrolled. Intron was given as 12 mu Sq daily and zidovudine-200mg orally every 4 hrs for 16 wks. Patients received placebo or *r*GM-CSF, 5-10 mcg/kg Sq daily for 16 wks.
Results. 12 patients have been enrolled. Mean length of time on study is 8.0 wks. 4 have completed 16 wks. Changes in mean hematologic parameters were:

Weeks	0	1	2	3	5	6	8
WBC ($x10^3$ cells/mm^3)	4.5	4.7	8.8	9.0	8.0	5.9	4.3
(range)		2.2-7.5/	2.0-18.7/	1.8-28.3/	2.5-28.0/	2.0-21.6/	2.0-10.4
Neutrophils(/mm^3)	2426	2652	5823	5280	6323	3820	2114
Platelet Ct ($x10^3$)	203	158	166	150	174	174	210
CD4 cells(/mm^3)	235	N/A	260	N/A	N/A	330	253
p24 (%+)	4	N/A	1	N/A	N/A	1	1

One patient developed severe hypoxemia and died. Moderate fatigue, anorexia, weight loss, headache, arthralgias, myalgias and fevers were seen during the first wks of therapy. 2 patients had bone pain. 1 patient had a complete anti-tumor response; the remainder had a partial anti-tumor response.
Conclusion. *r*GM-CSF resulted in dramatic and sustained increases in the WBC count and neutrophil count in patients receiving Intron and zidovudine. Doses of < 5mcg/kg of *r*GM-CSF may be useful. Adverse reactions were minimal. Early data do not suggest negative or synergistic *r*GM-CSF anti-HIV activity.

T.B.P.333

UPDATE ON PROGRAM STANDARDIZATION AMONG PUBLIC HEALTH LABORATORIES IN THE U.S.A. PERFORMING TESTS FOR HUMAN RETROVIRUSES

Mc[illegible]arr, William J., Jr.*; DiSalvo, A.**; Joseph, J.*** and Getchell, J.*. *State Hygienic Laboratory, (IA) **Bureau of Laboratories, (SC), ***Health Laboratories Administration, (MD)

Objective. To promote uniformity and assure quality of testing for HIV and other human retroviruses.
Methods. A survey of the fifty-four member laboratories of the Association of State and Territorial Public Health Laboratory Directors seeking information and data on human retrovirus programs was conducted in January 1989. A conference was held in March 1989 to achieve program standardization by conferee consensus.
Results. The sixth in the series of surveys shows continued growth of state testing programs and greater uniformity of procedures and practices. Problems identified through the survey together with topics selected by the conference planning committee determined the issues which workgroups of the conference addressed. The 1989 Consensus Conference was the fourth in the series. Consensus recommendations of this recent conference as well as those still valid and reaffirmed from previous conferences are included in the final report of the 1989 conference.
Conclusion. Through problem identification, consideration and consensus acceptance, public health laboratories in the U.S.A. have established an effective system for program standardization. Other countries have expressed interest in the program and some have established similar consensus building processes.

T.B.P.330

PSORIASIS IN HIV AB POSITIVE DRUG ABUSERS

Marco Masina*, A.Patrizi*, A.M.Costa*, E.Ricchi**, P.Costigliola**, F.Chiodo **.
*Istituto di Clinica Dermatologica -**Istituto Malattie Infettive; Universita' di Bologna, Bologna, ITALY.

Objective. To describe the onset of psoriasis during HIV infection in drug abuser patients.
Results. We report on 5 Italian patients, aged between 22 and 34 years, who all has been drug abusers for more than 2 years. They have never been affected by psoriasis before diagnosis of HIV infection was made, and three of- them have developed A.I.D.S. within the following 12 months. All patients presented small psoriatic lesions which covered less than 5% of the body surface. The lesions didn't worsen as in the three patients in which Opportunistic Infections occurred as in a symptom free patient. In only one case (with PGL) psoriasis exacerbated to a generalized flare of erithrodermic psoriasis, which however responded to therapy with topics.
Conclusion. Psoriasis is a disease of unknown etiopathogenesis, but it was suggested that infections may play a role of stimulus in genetically predisposed patients, and guttate psoriasis is described as a typical example of this event. Patients in whom HIV infection is associated with psoriasis have not frequently been reported. The Authors generally described homosexual men with wide spread of skin lesions which didn't improve under treatment and psoriasis often became uncontrollable when immune response was depressed during opportunistic infections. The dissimilar immune and infectious background of drug abusers can be explain the different aspect of the disease in our patients.

T.B.P.332

A NEW MORE SENSITIVE AND HIGHLY SPECIFIC ANTI HIV-1 ASSAY BASED ON RECOMBINANT PROTEINS.

Beckford, U., Berrisford, C., Duncan, R.J.S., Mackinlay, L. Weston, P. and *Tedder, R. Wellcome Diagnostics, Beckenham, Kent, U.K. and *University College and Middlesex Hospital School of Medicine, London, U.K.

Objective. To replace tissue culture raised viral lysate antigen with recombinant antigen in the Wellcozyme Monoclonal test and to further improve on the specificity seen in Wellcozyme competitive assays.
Methods. A recombinant DNA produced fusion protein containing the immunodominant regions of HIV-1 envelope and core proteins replaced whole viral lysate grown in CEM cells. Chemically inactivated horseradish peroxidase was included in the assay procedure and its effect on the rate of false positive reactions was determined.
Results. All of the 348 confirmed HIV-1 positive sera from AIDS, ARC and asymptomatic donors reacted (100% sensitivity) in the test. In 4 out of 5 serial samples taken from donors during seroconversion the assay detected HIV antibodies earlier than the Wellcozyme Monoclonal test. The assay was up to 10 fold more sensitive on end point dilutions of weakly reactive sera and had similar sensitivity with strongly reactive sera. None of 11542 negatives (9508 sera, 2034 plasmas) were reactive (100% specificity), although one sample was close to cut-off.
Conclusion. The use of recombinant antigen has improved the sensitivity with weak samples and the inclusion of peroxidase in the assay procedure has increased specificity. The majority of false positive reactions seen in previous tests of this type were caused by an inhibitory anti-peroxidase activity present in some serum samples.

T.B.P.334

T4a-"INTERNAL IMAGE"-BEARING ANTIBODIES IN SERA OF PATIENTS WITH HIV-1-INFECTION

Schedel, Ingolf; Winkelmann, P.; Dreikhausen, U.; *Flik, J.; and Deicher, H. Department of Internal Medicine, Division of Immunology, *Institute of Virology, Medical School Hannover, F.R. Germany.

Human immunodeficiency virus (HIV)-neutralizing antibodies could be detected in HIV-infected individuals by different groups. Obviously, the infection of the target-cell for HIV takes place by specific binding of the viral surface-glycoprotein (gp120) with the cellular CD4-receptor. This binding site is conserved in different isolates of HIV and linkage to CD4 as well as syncytia formation can be blocked by mouse-monoclonal antibodies reacting with the T4a-epitope.
Sera from patients with HIV-infection (n=120) and sera of an HIV-negative control group (n=50) were tested for antibodies reacting with the T4a-recognizing region of monoclonal antibodies in an ELISA-system. The HIV-positive sera showed significantly elevated binding activities in comparison with the sera of the control group ($p < 0.0001$). In the multiple regression analysis we determined a correlation of 0.34 ($p < 0.01$) between binding activity and linear combination of the following parameters: stage (WR-classification), T4 absolute, T8 absolute, T4/T8-ratio, Mérieux-test, opportunistic infections, lymphadenopathy syndrome and polyclonal serum-IgM. p24-positive patients (n=27) had lower binding-activities than patients without evidence for p24-antigenemia (n=13, $p < 0.02$).
The data reported here indicate the presence of antibodies reacting with the idiotypic region of T4a-recognizing monoclonal antibody-preparations in sera of patients with HIV-infection. These antibodies represent T4a-"internal image"-bearing network antibodies, which might have HIV-neutralizing function.

T.B.P.335 EVALUATION OF DIFFERENT ANTI-HIV REAGENTS THAT ARE AVAILABLE IN MEXICO.

Dominguez J.*; Morales C.*; Romero M.*; Moreno M.* and Orozco M.*
*Centro Nacional de la Transfusión Sanguinea, México, D.F.

Objetive.
To get to know percentage of sensitivity, specificity, false positives, false negatives of the reagents that are used in the mexican health care system.
Method.
6 traditional Elisa, 3 recombinant Elisa, 3 aglutination and 2 quick technology Elisa were evaluated with a known panel of 160 samples with aids, asintomatic seropositives, healthysamples. Other infections samples and blood donors samples
Results
The percentage of sensitivity was between 100 and 62.5% specificity between 98.3 to 82.5% false positive index turned out to be between 4.76 and 41.17% and the false negative index was from 37.5 to 0%.
Conclusion.
We found that two types of reagents. One of aglutination technology and the other one Elisa quick technology were not suitable for its use. The rest of the reagents turned out to be suitable for their use.

T.B.P.336 WHICH IS THE BEST LABORATORY MARKER WHEN FOLLOWING HIV-POSITIVE PERSON?

Reis, M.*; Sprinz, E.**; Kronfeld, M.**; Azevedo,M *; Seadi, C.*; Oravec, R.* et al.
*Laboratório Weimann de Porto Alegre
**Hospital de Clinicas de Porto Alegre

Objective. Establish the best laboratory marker when following HIV-positive patients.
Methods. It were annalyzed 60 ambulatory patients and 19 hospitalized HIV-positive patients. The following tests were executed Western-blot(WB- Dupont),Envacor HIV_1(EC-Abbott) and the presence of viral circulating antigen(HIV-Ag).
Results. The patients were agrupated in 5 groups as follow:
I positive WB 24, positive EC 24, negative HIV-Ag (43 ambulatory patients)
II positive WB 24, negative EC 24, negative HIV-Ag (4 hospitalized and 5 ambulatory patients)
III positive WB 24, negative EC 24, positive HIV-Ag (8 hospitalized and 10 ambulatory patients)
IV positive WB 24, positive EC 24, positive HIV-Ag(1 hospitalized)
V negative WB 24, negative EC 24, positive HIV-Ag (5 hospitalized and 3 ambulatory)
Conclusion. The best relation with anti-p24 antibody drop,anticenemia and clinical criteria of AIDS progression was obtained with EC-ABBott.Surprisingly, we did notfind the WB-Dupont confiable as a marker of AIDS progression.

T.B.P.337 COMPARISONS OF COMMERCIALLY AVAILABLE TEST FOR HIV ANTIBODIES USING ZAMBIAN SERA

Luo N.P*, Hira S.*, Siyambango J.*, Nshimbi R.*, Chipuka L.* Macwacwa*, *University Teaching Hosipital, Lusaka, Zambia.

OBJECTIVE. To compare the available test, the first generation, and confirmatory test with a view to decide the best Screening test and confirmatory test in Zambia.
METHODS. 3 Panels of Sera were set. Each panel of Sera was screened for HIV antibodies using a set of test from the first generation and new generation. Positives were confirmed using the standard confirmatory test like Western blots and immunofluorescent as well as using another ELISA as a confirmatory test.
RESULTS. Some of the first generation ELISA gave a very high false positive rate while the second generation were more reliable. Use of second ELISA as a confirmatory test was found to be as good as using the standard confirmatory i.e. Western blots.
CONCLUSION. Use of one of two other ELISA can be used as a confirmatory test. Immunofluorescent test was the other alternative to confirmatory test.

T.B.P.338 COMPARISON OF TWO HIV1 IMMUNOBLOT TECHNIQUES.

MANZALA P.[1], MAITHA G.[2]
1. Kenya Medical Research Institute
2. University of Nairobi, Microbiology Dept.

OBJECTIVE: To investigate the pattern of bands in strips of two electrophoretic immunoblot techniques to same sera.

METHOD: 72 adult sera, 51 positive for HIV1 and 21 seronegative were tested with an DUPONT and ANCOS Western blot electrophoretic techniques.

RESULTS: Comparison of tests with DUPONT as reference test. (Positive tests)

	GENERAL	P15	P17	P24	P33	P41	P55	P64/66	P160
(a) No of sera observed:	51	20	32	48	50	50	51	41	46
(b) % of sera +ve for both tests:	76	82	60	78	70	66	51	49	38
(c) Sensitivity:	95	100	90	95	99	94	95	84	53
(d) Specificity:	92	100	43	73	80	65	92	46	61

No gp 120 was found in ANCOS, but was present in 51% of DUPONT strips

CONCLUSION: Despite the high level of correspondence present when combinations of protein bands are considered, great variation was present on regarding individual proteins and glycoproteins in the two techniques.

T.B.P.339 LABORATORY TESTING FOR HIV 1 ANTIBODY TESTING IN CALIFORNIA: ANALYSIS OF CURRENT PRACTICES AND IMPROVEMENT EFFORTS

Peddecord, K. Michael*; Benenson, A.*; Hofherr, L.*; Ascher, M.**.
*San Diego State University, San Diego, California, USA.
** California Viral and Rickettsial Disease Laboratory, Berkeley, California, USA.

Objective. This program uses HIV antibody testing as a model to develop and evaluate methods of monitoring and improving laboratory quality.
Method. Using a "blind" proficiency test system, serum samples with known HIV content were submitted as clinical specimens by physicians, clinics and hospitals to their usual sources of testing. Currently 20 EIA laboratories and 12 confirmatory laboratories in five states are included. An open proficiency test and a written survey to a sample of 130 HIV laboratories in California has also been completed in order to profile HIV testing practices and plan future improvement activities.
Results. Performance on EIA screen tests has been excellent with fewer than 2% incorrect results. Western Blot confirmatory tests are more problematic with commercial laboratories reporting a high proportion of positive specimens as indeterminate. While public health laboratories in California use a well standardized indirect immunofluorescence test, commercial reference laboratories use both licensed and unlicensed Western blot reagents with a variety of interpretive criteria for confirmatory testing. Analysis of report content and format, shows potential communication problems between laboratory and physicians. There is no consensus on the content and format of EIA screening results or confirmatory testing. Many reports were cluttered with "boiler plate" of questionable utility, making it difficult to find relevant information and results. Approximately half of confirmatory laboratories using Western blot reported band patterns; however, there was no consensus on what were clinically important bands.
Conclusions. HIV antibody testing has the potential to be a highly sensitive and specific system However, use of a variety of unlicensed reagents for confirmatory testing, lack of agreement on WB interpretive criteria and performance of testing in more than 220 laboratories with a wide range of test volume and expertise suggests the need for continued close monitoring. In order to correct these problems, state agencies and professional organizations responsible for laboratories, are undertaking regulatory and educational interventions which seek to bring a higher level of standardization to confirmatory testing and referral of indeterminate specimens to public health laboratories for additional testing.

T.B.P.340 CROSS-REACTIVITY BETWEEN ELISA's FOR DETECTION OF HIV-1 AND HIV-2

Bouzas,María Belén*;Muchinik,G*;Picchio,G*;Simon,F**;Mathov, I**;Brun Vezinet,F**
*IIHEMA,Academia Nacional de Medicina,Buenos Aires,Argentina,**Hôpital Claude Bernard,Paris,France.

Objective. To study the cross-reactivity of HIV-1 and HIV-2 in ELISA assays.
Methods. Sixty sera from hemophiliacs were tested for antibodies HIV-1 (HIV-1 recombinant, Abbott) and confirmed by means of ENVACORE (Abbott) and RIPA. In all the sera, HIV-2 antibodies were determined using a commercial available anti-HIV-2 ELISA test (ELAVIA 2) (Diagnostics Pasteur). Sera reacting positive for HIV-2 were confirmed by RIPA using HIV-2-ROD.
Results. HIV-2 ELISA reactivity was observed in only 1 out of the 27 HIV-1-negative samples, but HIV-2 reactivity was found in 27 out of the 33 HIV-1-positive sera. All the HIV-2 samples positive by ELISA were negative by RIPA, which difference was statistically significant ($p < 10^{-6}$). No significant differences were observed between the presence or absence of HIV-1 core proteins and HIV-2.
Conclusion. These results confirm the high degree of serologic cross-reactivity between gene products of HIV-1 and HIV-2(ELISA).
(Supported by a grant from Fundación Roemmers).

T.B.P.341

FAILURE OF ELISA AND WB TESTING TO DETECT HIV INFECTED SUBJECTS.

Mazzella, Emilio; Ippolito,G.**; Micali,M.*; Mirolo,M.; Pezzella, M.***; Angeloni ,P.*
*Italian Red Cross, National Center for Blood Transfusion, **"Lazzaro Spallanzani" Hospital for infectious diseases, *** University of Rome-Italy

Objective. To assess the efficacy of ELISA and WB test routinely used in laboratory setting to detect HIV infected subjects.
Methods. All sexual partners of seropositive blood donors were tested by ELISA and WB; most negative for anti-HIV were in situ hybridised (ISH) with an SP64 plasmid containing the nine-kilobase SstI-SstI viral insert lambda BH10 tagged by inserting an antigene sulfone group into cytosine of the denaturate cDNA.
Results. Studied population was: 27 partners (3 males and 24 females) of 27 seropositive blood donors (25 males and 2 females); the distribution by risk group was: homosexual male 3.7%, bisexual male 11.1%, intravenous drug addict 55.5%, heterosexual contacts 22.2%, not known 7.4%.
In 3 cases the partner, belonging to risk group, was the source of infection. Seven partners negative to serological assessment resulted positive at ISH test.
Conclusions. Regular sex partner of HIV infected subjects may be infected also in presence of negative serologic assessment, and ISH may be useful to detect marker of infection at least 3 months before the ELISA and WB positive results.

T.B.P.342

CORRECTION OF FALSE-POSITIVE RESULTS OF ELISA OF IMMUNODEFICIENT STATE

Kukaine, R.*, Sochnev, A.**, Svirska, Regina*, Burstein, A.**, Shif, B. **, Denisova, A.**
*August Kirchenstein Institute of Microbiology, Latvian SSR Acad.Sci., Riga
** Riga Medical Institute

Summary. A mass-scale serotesting of various subpopulations in order to detect HIV infection demonstrated that ELISA is a most widespread method of examination, and, irrespective of its high specificity, yields false-positive results in a definite percent of cases.
Methods. Serological testing for the presence of antibodies to AIDS virus was carried out by ELISA with home-produced and imported test-systems, the obtained results were confirmed by immunoblotting.
Results. The results of ELISA were corrected by the following: adsorption of sera (the test and control ones) by the pool of trombocytic antigen, screening of the sera under study prior to and after treatment with the trombocytic antigen in the panel of T-lymphocytes of test-donors with the known spectrum of HLA-antigens. Adsorption by the pool of trombocytic antigen, with only class I HLA specificities represented, eliminated antibodies to the A, B and C loci of the HLA system. Testing in the panel of T-lymphocytes was carried out to determine the degree of serum purification of HLA - A, B, C antibodies.
Conclusion. In false-positive individuals after sorption by the trombocytic antigen the sera in ELISA became negative; this was confirmed in the panel of T-cells. It can be concluded that the false-positive results of ELISA may be due to antibodies to class I antigens of the HLA system.

T.B.P.343

SEROSURVEY OF WOMEN IN A MATERNITY WARD

A.Santos Pinto, W.Canas Ferreira, E.Prieto, R.A.Sousa-Institute of Hygiene and Tropical Medicine, Ministry of health,Cape Verde.

OBJECTIVE - To study the prevalence of hepatitis B markers and HIV antibodies in parturients receiving clinical care at a hospital in a Cape Verde island(West Africa).
METHODS - During January and May 1988 serosurvey of the vertical transmission of hepatitisB virus was performed on 356 parturients and their babies. Specimens were analyzed also for anti HIV antibodies. Elisa and Western blot were the methods employed.
RESULTS - 22(6,17%) of the mothers were HBs Ag positive and 78 (21,91%) were HBs Ab positive. Study of HIV prevalence is in progress. The results will be presented and discussed at the Conference.

Donneurs et receveurs de sang et de produits sanguins
Recipients and Donors of Blood and Blood Products

T.B.P.344

LOOKBACK: AN UPDATE ON THE NEW YORK EXPERIENCE

Gaynor, Suzanne; Kessler, D.; Andrews, S.; Berge, P.; DelValle, C.; New York Blood Center, New York, NY USA.

Objective: To evaluate results and assess costs of the Lookback Program.
Methods: A lookback of previous donations from 1358 anti-HIV positive blood donors identified since April, 1985 has been carried out. 203 hospitals in the greater New York region have been notified of receipt of 2417 components back to May, 1980.
Results: To date, 1627 reports have been received from hospitals (69% response rate); 1453 or 89% of components were transfused. Of these recipients, 1079 or 74% are deceased. Recipients known to have been discharged equal 329. Of these, 237 or 72% have been tested; 99 or 42% are HIV antibody positive. The positivity rate was highest in patients transfused in 1984; 48 patients or 61% of those tested were seropositive. In 1985, 16 patients (52%) were positive. There were no positive recipients in 1980. There are 66 recipients (70%) between 18 and 70, which may be a surrogate measure of sexual activity and potential transmission. The cost to the New York Blood Center to date has been approximately $843,440, including $75,000 in grant support or approximately $8,500 per positive recipient located. This figure does not include hospital costs which are substantial, nor does it include the cost of Lookback-generated lawsuits.
Conclusion: The 99 seropositive Lookback recipients identified constitute only a small fraction of the total estimated HIV infected population in the country. Despite its minimal public health impact, Lookback fulfills our obligation to notify about information of significance to another's health.

T.B.P.345

THE ITALIAN HEMOPHILIC REGISTER AND NATURAL HISTORY OF HIV INFECTION.

Schinaia, Nicola*; Ghirardini, A.**; Valdarchi, C*; Gringeri, A.***; Mariani, G.** and Mannucci P.M.***.
* Istituto Superiore di Sanità, Rome, ** University of Rome, *** University of Milano, (Sterring Committee of the Scientific and Medical Board of "Federazione dell'emofilia".

Objectives. To present the results of a nationwide survey of all population affected by congenital coagulation disorders, with the aim to evaluate the time-trend of the incidence of HIV-1 seropositivity and AIDS in the Italian Hemophilia population through a retrospective national cohort study.
Methods. This project is divided up into two phases. 1. the set up of the Register (National Hemophilia Survey), and 2. the evaluation of the spread of HIV infection. The National Hemophilia Survey carried out between September and November 1988 was performed by a standard questionnaire, with an individual code to ensure confidentiality sent to all the Hemophilia Centers to collect demographic and clinical informations. Data have been analysed using a database program.
Results. As of 15 January 1988, 12 Hemophilia Centers had replied. At this the information regarding 859 subjects were collected. On the whole a prevalence of HIV-Ab positivity of 21% was found.
Conclusions. This National Hemophilia Survey has been the first comprehensive evaluation of the Italian population affected by congenital coagulation defects. The Hemophilia Centers partecipate entusiastically to this cooperative project. From this Nation Survey, though the analysis of the data is still incomplete, a prevalence of HIV-Ab positivity of 21% was shown.

T.B.P.346

TRANSFUSION-ASSOCIATED (T-A) AIDS CASES IN ITALY.

Schinaia, Nicola; Valdarchi, C.
Istituto Superiore di Sanità, Rome, Italy.

Objectives. To present an update of the patients with AIDS due to blood transfusion, and to discuss the importance of an active surveillance system of T-A AIDS within the overall AIDS surveillance. The peculiarities of this specific surveillance will also be discussed.
Methods. A database has been created including all the subjects for whom the only ascertained risk factor was the reception of blood transfusion. It has been derived from the National AIDS Register, including other pieces of information collected by means of a special standardized form. The analysis has been carried out using different BMDP programs.
Results. As of 31st December, 1988, 53/3008 (1.8%) patients were reported with T-A AIDS, 5 of which were below 14 years of age (9.4%). At the same date, the case-fatality rate was 41.5%. Clinical and epidemiologic information will be presented, as well as the mean lag-time between infection and the development of full-blown AIDS.
Conclusions. At the end of 1988, the relative proportion of T-A AIDS was slightly lower than at the end of 1987, in Italy; the case-fatality ratio is also less for this subgroup of patients than for all the other AIDS subjects. The standard reporting form for AIDS has proven inadequate to describe both the pattern and the natural history of the syndrome in T-A patients. Nor have the reporting physicians provided enough data, as a result of an investigation carried out early in 1988. Thus a network which includes the national AIDS unit, the reporting physicians, the unit(s) where the blood was administered, and the blood bank is being implemented.

T.B.P.347 HIV-1 p24 ANTIGEN SCREENING OF MALE BLOOD DONORS IN LOCALITIES WITH HIGH HIV-1 ANTIBODY PREVALENCE

Transfusion Safety Study Group* represented by Busch, Michael**
* Participating institutions in New York City, Miami, Detroit, Seattle, San Francisco, and Los Angeles, USA.
** Irwin Memorial Blood Centers and University of California, San Francisco, California, USA.

Objective. To assess the frequency of HIV-1 p24 antigen (Ag) positivity among male donors in high anti-HIV-1 prevalence areas in the city of San Francisco (SF) during a period with a high rate of HIV seroconversions. Methods. The SF component of the TSS/NHLBI Donor Repository has 25,892 sera collected in late 1984-early 1985, before anti-HIV screening began. Overall prevalence of anti-HIV-1 among these specimens was 0.24%. A subset of 2,297 sera was selected among males aged 18-44 years with addresses in SF Zip codes having one or more anti-HIV-1(+) Repository donations; the anti-HIV-1 prevalence of the subset by prior testing was 1.08%. HIV-1 p24 Ag testing used Abbott's ELISA and neutralization (confirmatory) reagents; if initially p24 reactive, anti-HIV-1 was reassayed (Genetic Systems, Inc.).

Results.

	HIV-1 p24 Antigen Result	Number (%)		
Anti-HIV-1 Status	Tested	Initially Reactive	Repeatably Reactive	Neutralized
Positive	25	3 (12%)	3 (12%)	3 (12%)
Negative	2,272	9 (0.4%)	4 (0.18%)	0* (0%)

* Zero falls within the 95% CI of a Poisson distribution with a mean of 3.

Conclusion. No HIV-1 p24 Ag(+) donations were found among 2,272 anti-HIV-1(-) persons in a population that yielded 25 anti-HIV-1(+) results. Given the present anti-HIV-1 prevalence of 0.012% in US donors,over 200,000 contemporary donations would be needed for a similar evaluation of the antigen:antibody ratio. (Sponsored by Contracts # N01-HB-4-7002 and N01-HB-4-7003 of the National Heart Lung and Blood Institute).

T.B.P.349 MULTICENTER EVALUATION OF A RECOMBINANT BASED HIV-1/HIV-2 COMBINATION SCREENING ENZYME IMMUNOASSAY.

F. Avilez*, L. Guertler*, H. Joller-Jemelka*, S. Ranger*, S. Siedl*, F. Simon*, D. Sondag*, H. Hampl**, B. Schoen**, H. Troonen**. * European Clinical Study Group. ** Abbott Laboratories, Wiesbaden-Delkenheim, Federal Republic of Germany (FRG).

OBJECTIVE: To evaluate a newly developed screening assay which utilizes HIV-1 and HIV-2 recombinant proteins. A significant number of HIV-2 infected individuals would not be detected with current HIV-1 screening assays.
METHODS: An enzyme immunoassay (EIA) was developed which utilizes both HIV-1 recombinant envelope and gag proteins and a recombinant HIV-2 envelope protein on the solid phase. The sensitivity and specificity of this EIA was evaluated on serum or plasma from normal blood donors and from individuals infected with HIV-1 or HIV-2: results were compared to the current recombinant-based HIV-1 EIA.
RESULTS:

		No. Repeatably Reactive (%)	
Type of Specimen	No. Tested	HIV-1 EIA	HIV-1/ HIV-2 EIA
Blood Donors	5029	5 (0.10)	8 (0.16)
HIV-1 Seropositive	286	286 (100)	286 (100)
HIV-2 Seropositive	202	154 (76.2)	201 (99.5)

Both assays had a specificity of >99.8% and detected 100% of the known HIV-1 specimens. The sensitivity of HIV-1 EIA and HIV-1/HIV-2 EIA for detecting HIV-2 seropositives was 76.2% and 99.5% respectively.
CONCLUSION: The addition of HIV-2 envelope proteins to HIV-1 proteins already on the solid phase preserved the performance of the HIV-1 EIA and significantly improved the detection of HIV-2 antibodies.

T.B.P.351 USE OF RAPID ASSAYS FOR ANTIBODY TO HIV IN BLOOD DONORS, PERSONS PRACTICING HIGH RISK BEHAVIORS AND SUSPECTED AIDS CASES IN GHANA

Mingle, Julius*, Mitchell, S.**; Osei-Kwasi*.
*Noguchi Memorial Institute for Medical Research, Accra, Ghana, Africa;
**Family Health International, Research Triangle Park, North Carolina, USA.

Objective. To evaluate three tests for antibody to HIV which do not require specialized equipment in three different populations in Ghana.
Method. Seven laboratories in Ghana participated in the study. Two thousand specimens from 3 populations were tested with HIVCHEK, SERODIA and Retrocell. The 3 populations were blood donors, persons practicing high risk behaviors and suspected AIDS cases. Each specimen was also tested by ELISA for antibody to HIV-1 and HIV-2. All positivies were confirmed by Western Blot.
Results. Analysis is currently being performed to determine sensitivity, specificity, and predictive value of the tests in each of the populations tested. These results will be reported.
Conclusion. Many laboratories in developing countries are not equipped to perform the standard tests for HIV antibody, ELISA and Western Blot. Although the newly developed tests for HIV were designed primarily for screening blood donors, many of these labs will be asked to test suspected AIDS patients and persons thought to be at high risk of acquiring HIV. These tests have been evaluated for use in these populations under true field conditions.

T.B.P.348 HIV INFECTION IN WESTERN BLOT INDETERMINATE BLOOD DONORS

Jackson, Brooks*; Hanson M**; Kwok S***; Stramer S****; Balfour HH JR*****; MacDonald K****** et al. *St. Paul Red Cross, St. Paul, MN, USA, **Memorial Blood Center, Mpls., MN, USA, ***Cetus Corporation, Emeryville, CA, USA, ****Abbott Laboratories, North Chicago, IL, USA, *****University of Minnesota, Mpls., MN, USA ******Minnesota Dept. of Health, Mpls., MN, USA

Objective. To determine whether U.S. Upper Midwest blood donors with indeterminate HIV-1 Western blot results are HIV-1 infected.
Methods. 187 volunteer blood donors who had tested repeatedly reactive by enzyme immunoassay (EIA) and had at least one HIV-1 characteristic band on Western blot (but not positive) were asked to return for an interview and blood testing. We obtained information regarding HIV risk factors and peripheral blood specimens for the following tests: HIV-1 antibody (two different EIAs and a licensed Western blot), HIV-2 antibody EIA, HIV-1 serum antigen, HIV-1 culture using both RT and HIV-1 antigen detection assays, HTLV-I antibody EIA, and PCR analysis using an HIV-1 gag primer pair.
Results. 100 of 187 (53%) blood donors agreed to participate. There was no significant difference between the blood donor participants and nonparticipants in terms of age, sex, or Western blot band pattern. 65 of 100 were still repeatedly reactive for HIV-1 antibody by at least one HIV-1 EIA. All 100 denied risk factors for HIV-1 infection. 92 of 100 were still indeterminate by Western blot and 8 were negative after 1-46 months follow-up. None were positive by HIV-1 Western blot, HIV-1 serum antigen EIA, HIV-2 antibody EIA, HIV-1 culture, or HTLV-I antibody EIA. HIV-1 PCR analysis results are pending.
Conclusion. These data indicate that blood donors who are indeterminate by HIV-1 Western blot and lack risk factors for HIV infection are not infected with HIV-1.

T.B.P.350 HUMAN IMMUNODEFICIENCY VIRUS ANTIBODY SCREENING OF BLOOD DONORS - AN INTERNATIONAL SURVEY.

Perrault, B; Mankikar, S; and Adatia, A.
The Canadian Red Cross Society, Ottawa, Canada

Between October 1985 and March 1988, the Canadian Red Cross Society (CRCS) conducted three surveys on international practices of screening blood donors for anti-HIV. During this period, the reported cases of AIDS per 100,000 population increased from two in 1985 to six in 1988. At the same time, the mortality rate due to AIDS also increased from 1/100,000 in 1985 to 4/100,000 in 1988. The number of blood transfusion associated AIDS cases increased from 1.8% in 1985 to 3.6% in 1988. In 1985, 17/22 countries surveyed were screening the blood donors for anti-HIV, whereas, in 1988, 31/33 countries were screening blood routinely. Of the 18 countries from which information was available, 12 countries reported a decreasing trend in the anti-HIV seroprevalence rate, five countries reported a stable trend and the remaining one reported an increasing trend. The confirmed positive anti-HIV rate in 1988 varied from 0% to 0.64% with the majority of countries reporting the prevalence rate below 0.005%. In 1985, the majority of countries had already implemented self-exclusion programme and provided alternate test sites. Most of the countries were also reporting antibody status to the donors and maintaining confidentiality of their test results. By 1988, of the 33 countries surveyed, two had already started screening donors for anti-HIV-2 and the additional 14 countries were conducting feasibility studies. Additional information based on the survey planned for March 1989, will also be presented.

T.B.P.352 "THE GIFT RELATIONSHIP REVISITED:" HIV SEROPREVALENCE OF BLOOD DONORS AND OTHER LOW-RISK GROUPS IN AFRICA

Torrey, Barbara Boyle, Mulligan, M. and Way, P.
Bureau of the Census, Washington, D.C., U.S.A.

Objective. HIV survey data from 22 African countries reenforces the conclusion of Titmuss' The Gift Relationship that the quality of donated blood varies considerably.
Method. Compared HIV seroprevalence estimates from non-random sample surveys of blood donors and other low-risk groups (i.e., pregnant women) in the same year and location. Data from small sample sizes and from small differences in seroprevalence (the significance of which is tested) are discarded.
Results. HIV seroprevalence for urban blood donors and other low-risk groups in 10 of the 22 countries was similar; in 3 countries, donor seroprevalence was lower; but in 9 countries it was higher (6 of which achieved $p < 0.02$). In regions outside the capital, the relationship is reversed. In 7 of the 10 regions, the HIV seroprevalence of donors is lower than other low-risk groups. In all 9 countries with data on gender of blood donors, male donors outnumber females; in 7 of the 9 countries, the female HIV seroprevalence rate was higher than males. Longitudinal data, available on blood donors in 9 countries, suggest that 3 countries have shown no seroprevalence change, 4 have shown a modest decrease, and 2 have shown an increase.
Conclusion. Data suggest that blood donors in many capital cities are not a random population apparently, and their higher HIV seroprevalence, especially for women, is troubling. Blood banking procedures should be reevaluated in light of this HIV data, as should the gift relationship itself.

T.B.P.353 THE IMPACT OF AIDS ON BLOOD TRANSFUSION SERVICES AT THE UNIVERSITY TEACHING HOSPITAL, LUSAKA

Dr. Abraham Mwile, University Teaching Hospital (UTH), Lusaka, Zambia

Objective: To describe the impact of AIDS on the Blood Transfusion services provided by the UTH.
Method: The data was obtained from annual records and my full participation in the recruitment of blood donors.
Results: The number of blood units discarded on account of HIV positivity is rising and thus making it more difficult for the Blood Bank to meet the ever increasing hospital requests.

Year	No. of Donors	No. of HIV+ve	%
1987	7457	678	9
1988	5505	1037	18.8

Conclusion: The AIDS pandemic relentlessly continues to be a collosal challenge to the meagre blood transfusion services offered by the UTH.

T.B.P.354 HIV ANTIGEN TESTS AMONGST NEW BLOOD DONORS

Das, P.C.; de Vries, A.H.; McShine, R.L.; Smit Sibinga, C.Th.
Red Cross Blood Bank Groningen-Drenthe, Groningen, NL.

A 'window-phase' (3-12 weeks) may exist following HIV infection when no antibody could be demonstrable but HIV antigen may appear in the blood. We have tested this possibility in first time (new) blood donors, since in our blood bank 60,000 annual donations have been followed over 3 years without additional seroconversion amongst repeat donors.
Included also in this study are 4 donors who have stopped donating because of the 'risk factors'; 5 W. blot positive donor sera and 3 'tricky sera' (only P24/P55) detected by a first generation test during 1985. Antigen assay is based on enzyme immuno assay system (Vironostika, Organon). All samples are tested in parallel by routine antibody assay (Wellcome).
Results:

TESTS	NEW DONORS	HIV antibody positive	Donor with risk factors	Tricky sera
	157	5	4	3
Antigen (Organon)	2 pos	neg	neg	neg
Antibody (Wellcome)	neg	pos	neg	neg

Our results indicate Vironostika did not show any reactivity in the 'tricky sera' and to antibody containing sera, suggesting its specificity. 2/157 normal sera showed initial reactivity, but not reproducable. However, application of the test may be profitable in risk groups and in patients where antigenemia has prognostic and therapeutic significance.

T.B.P.355 INDETERMINATE HTLV-1 WESTERN BLOT RESULTS IN BLOOD DONORS: ABSENCE OF INFECTIVITY TO RECIPIENTS OF BLOOD

Van Der Poel, Cees*; Lelie, N.**; Reesink, H.*; Ehlers, P.**; Bakker, E.**; Huisman, H.**
* Red Cross Blood Bank, Amsterdam, ** Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, Amsterdam, The Netherlands.

Objective. To investigate if donor blood with indeterminate test results in HTLV-1 Western Blot (WB) transmits HTLV-1 to recipients.
Methods. Serum samples from blooddonors (n=5,332) and recipients (n=392), who participated in a prospective study for posttransfusion hepatitis, were tested for HTLV-1 antibodies with a commercially available ELISA. The recipients were followed-up for 6 months. Repeatedly ELISA reactive samples were tested for confirmation with commercially available WB strips, and ^{125}J-RIPA developed in our institute.
Results.

		ELISA reactive		Western Blot		^{125}J-RIPA	
	n	initially	repeatedly	pos	indet.	pos	indet.
donors	5,332	109 (2.04%)	19 (0.36%)	0	6	0	0
recipients	392	5 (1.28%)	1 (0.26%)	0	1	0	0

The 6 recipients who received blood products from 6 donors with indeterminate HTLV-1 WB, were non-reactive in HTLV-1 WB and ^{125}J-RIPA, with serum samples obtained 0, 3 and 6 months after transfusion.

Conclusions. Blood products from donors with indeterminate results in HTLV-1 Western Blot, do not transmit HTLV-1 to recipients.

T.B.P.356 "CASE CONTROL STUDY IN HIV SEROPOSITIVITY IN HEMODIALYSIS PATIENTS"

R. SALOMÃO, C. ACCETTURI, R. BARATA, J. SALVADOR, I.M. LONGO, N.F. MENDES. Escola Paulista de Medicina and Casa de Saude Santa Marcelina São Paulo SP Brasil

To investigate the extent of HIV infection among dialysis patients, we studied 117 patients of the hemodialysis unit of the Santa Marcelina Hospital, east region of São Paulo city, to assess anti-HIV (ELISA and Western Blot), immunological status, exposure to blood transfusion and time on hemodialysis. Twelve patients were positive with the ELISA technique and 9 (7,7%) were confirmed by Western Blot. Risk factors other than blood transfusion were ruled out in all 9 patients. Every positive patients was compared to 3 controls matched for sex. The mean number of units of blood transfused to cases was 29.3 units and 26,7 units for the controls. The mean time on hemodialysis was 28.2 and 27.2 months, respectively for cases and controls. Except for two patients who had chronic lymphadenopathy, all the cases had no clinical manifestations associated to HIV infection at that time. The risk of HIV infection was neither associated to the number of blood units transfused nor the time on hemodialysis. OKT4/OKT8 ratio was ≤ 1 in all truely infected patients. After 12 months, 3 out of 9 died, and 1 developed ARC. The others have been assyntomatics. New investigations showed one more infected by HIV, who is also assyntomatic yet. The prevalence of HIV infection observed in this study is rather high. This finding stresses the need for the dialysis units personnel to carefully with recommended preventive measures.

T.B.P.357 A CLINICAL AND SEROLOGICAL FOLLOW-UP OF HIV 2 - - POSITIVE PATIENTS FROM GUINEA-BISSAU (WEST AFRICA)

Celestino Costa, Wanda F.Canas Ferreira, J.Champalimaud, Kamal Mansinho, A. Santos Pinto, Francisco Dias, Paulo Mendes, Augusto P. Silva, E. Prieto, J.L.Baptista, C.Araújo, J.Baptista Marques, J.Brandão, Rita Albuquerque Sousa-Institute of Hygiene and Tropical Medicine-Dept.Microbiology and Dept.Clinical Tropical Medicine-Ministry of Health, Guinea-Bissau.

OBJECTIVE - To establish the clinical and laboratorial features of HIV 2 infection and to determine parameters of these infection related to disease progression in people from Guinea-Bissau
METHODS - 59 asymptomatic persons with documented (serological) HIV 2 infection in 1986 were re-evaluated in 1988 by their medical history, physical examination and laboratory tests. The serological HIV profiles were determined and compared by ELISA and W.B.analysis; antibodies anti HSV, CMV, and EBV and B_2-microglobuline by ELISA, immunoglobulines by ID and lymphocyte phenotype by monoclonal antibodies. 40 healthy HIV negative persons were enrolled as a control group.
RESULTS - The parameters given below were associated with disease progression. Higher relative and absolut members of CD8 and lower CD4/CD8 ratio was associated with disease progression-No direct relationship was seen between CMV and HIV serological status. More results, statistics and conclusion will be presented.

T.B.P.358 LATEX AGGLUTINATION TESTING OF WHOLE BLOOD FOR HIV-1 IN THE FIELD.

Musgrave, S.*; Biryahwaho, B.**; Ojiwya, A.**; Ndumu, J.**; Downing, R.***; Sempala, S.**
*Columbia University, New York, USA, **Uganda Virus Research Institute, Entebbe, Uganda, *** WHO, Entebbe, Uganda.

OBJECTIVE: To determine the reliability and practicability of using a Latex Agglutination (L.A.) test (RECOMBIGEN donated by Cambridge Bioscience) to test for HIV antibodies in a field serosurvey in Rakai, District, a highly endemic area of Uganda.
METHODS: RECOMBIGEN L.A. is a rapid (5min) visually scored test for antibody to recombinant GP 120 and 41. The test was performed on finger prick or venipuncture whole blood samples, immediately after samples were obtained in the subjects' home in a community based survey. 145 subjects were tested by both L.A. and serum Elisa (RECOMBIGEN) for antibody to HIV-1.
RESULTS: Technical staff expressed satisfaction with the ease and readability of the method. Sensitivity was 100% but specificity only 54% compared to the Elisa. Positive predictive value was 36%.
CONCLUSION: Despite ease of use and high sensitivity, the low specificity of the RECOMBIGEN L.A. test in this setting indicates that further development may be needed for use on whole blood in the field. Reasons for the high rate of false positives are being investigated.

T.B.P.359

ANTI-HIV LOOKBACK PROGRAMME OF THE CANADIAN RED CROSS SOCIETY.

HOGAN, V; MANKIKAR, SADANAND; ADATIA, A; AND WHITTEMORE, N.B.
THE CANADIAN RED CROSS SOCIETY, OTTAWA, CANADA.

BETWEEN NOVEMBER 1985 AND DECEMBER 1988, THE CANADIAN RED CROSS SOCIETY (CRCS) COLLECTED OVER 3.7 MILLION UNITS OF BLOOD. OF THOSE, 395 (0.011%) WERE FOUND TO BE WESTERN BLOT (WB) POSITIVE. A TOTAL OF 3.2 MILLION UNITS WERE COLLECTED FROM REPEAT DONORS, THUS IT IS CONCEIVABLE THAT SOME OF THE WB POSITIVE DONORS MAY HAVE DONATED PREVIOUSLY. IN ORDER TO ESTABLISH THE DISPOSITION OF THE COMPONENTS PREPARED FROM SUCH DONATIONS AND TO IDENTIFY THE RECIPIENTS OF THESE PRODUCTS, A LOOKBACK PROGRAMME WAS IMPLEMENTED. UNDER THIS PROGRAMME, WHEN A DONOR IS CONFIRMED TO BE POSITIVE FOR ANTI-HIV AS A RESULT OF A ROUTINE SCREENING OR AN INVESTIGATION OF POST-TRANSFUSION AIDS CASES, A SEARCH IS INITIATED. EFFORTS ARE MADE TO TRACE ALL THE COMPONENTS AND TO ESTABLISH THE SEROCONVERSION STATUS OF THE RECIPIENTS OF THESE COMPONENTS. IF THE PLASMA HAS BEEN SHIPPED TO THE PLASMA FRACTIONATORS, THE INFECTED UNITS ARE RECALLED. CRITERIA FOR TERMINATING LOOKBACK CASES INCLUDE AT LEAST TWO DONATIONS PRECEDING THE FIRST SEROPOSITIVE OR INFECTIOUS DONATION WITH NO EVIDENCE OF HIV TRANSMISSION OR WHEN THE LIMITATION OF HOSPITAL OR CENTRE RECORDS IS REACHED.

LOOKBACK HAS BEEN COMPLETED FOR 46 OF THE 395 SEROPOSITIVE DONORS. THE REMAINING CASES ARE BEING INVESTIGATED. MAJOR HINDERANCE IN THE COMPLETION OF LOOKBACK CASES SEEMS TO BE THE DIFFICULTY IN FOLLOWING UP THE RECIPIENTS. A NUMBER OF RECORDING GUIDELINES ARE BEING DEVELOPED AND IMPLEMENTED BOTH IN CRCS AS WELL AS IN THE HOSPITALS.

T.B.P.360

RETROSPECTIVE STUDY OF POSTTRANSFUSION HIV INFECTIONS

Gathof, Birgit*; Bäcker, U*; Gathof, G*;
Gürtler, L**; Eberle, J**; F. Deinhardt**
*Bavarian Red Cross Blood Transfusion Service, Munich, **Pettenkofer Institute, University Munich, Federal Republic of Germany

Objective. Between May 1, 1986 and Dec. 31, 1988 26 recipients (17 male, 5 female, 1 newborn male, 3 of unknown sex) of blood transfusions were reported anti-HIV positive; the 285 donors involved were traced for testing for anti-HIV.
Methods. Donors who had not donated blood after the donation involved were tested for anti-HIV in ELISA, Western blot and (since available) for HIV-DNA by PCR. Blood donors who had already given one or more donations that were tested negative for anti-HIV after the donation associated with the posttransfusion (PT) HIV infection were considered uninfected.
Results. Examination of 277 donors established that 21 anti-HIV positive cases were not linked to the blood donations. One of these 21 cases was only positive in ELISA and one was a passive transmission of anti-HIV to a newborn. Eight donors involved in 5 cases were not traced.
Conclusion. In all the cases of PT HIV infection for which every donor involved could be traced all donors were anti-HIV negative, and other sources of HIV-infection such as manufactured blood and plasma products of a different origin, sexual transmission, etc. must be considered.

T.B.P.361

DETERMINATION OF ERYTHROCYTE ADENOSINE DEAMINASE ACTIVITY IN ANTI-HIV SERONEGATIVE HOMOSEXUAL MEN WITH LATENT HIV INFECTION

Ferrazzi Mario+, De Rinaldis,M.L.+, Pezzella,M.+, Caprilli,F. ++, Bozzi,A.+++ and Strom,R.+++
+Institute of Infectious Diseases, +++and Human Biopathology Department, Policlinico Umberto I, University of Rome; ++Dermosyphylopatic Institute S.Gallicano, Rome, Italy.

Objective. The aim of our research was to evaluate the erythrocyte adenosine deaminase/pyruvate kinase activity (ADA/PK) in anti-HIV seronegative, non intravenous drug abusers, homosexual men with multiple partners (ELISA test, Western blot confirmed).
Methods. Erythrocytes from 21 heparinized blood samples were examined. The ADA and PK activities were carried out on lysed purified erythrocytes using an Abbott VP bichromatic analyzer. Sixty patients affected by LAS, ARC or AIDS were used as positive control and thirty healthy blood donors as negative control.
Results. The use of ADA/PK ratio corrects for high levels of ADA activity due to increased erythropoiesis. Only one out 21 subjects studied showed an elevated ADA/PK ratio (0.225) as observed in positive control groups (LAS: 0.154 ±0.022; ARC: 0.167±0.022; AIDS 0.205±0.026; healthy subjects: 0.117±0.019). This homosexual man was then found to be latently HIV infected by "In situ" hybridization performed on cytocentrifuged peripheral blood mononuclear cells using an SP 64 plasmid containing the SstI-SstI viral insert lambda BH 10 recombinant clone.
Conclusions. Since the mean incubation period of the HIV infection is currently extimated to be in the range of 4 years, the ADA/PK ratio could be of help for the screening of latent HIV infection.

Manifestations cliniques
Clinical Manifestations

T.B.P.362

CLINICAL CHARACTERISATION OF HIV2 DISEASE IN WEST AFRICA

TUMANI CORRAH EGBOGA A.A. WILIKINS A,B.GAYE I, WHITTLE H AND GREENWOOD B.
MEDICAL RESEARCH COUNCIL, FAJARA, THE GAMBIA.

OBJECTIVES: Particular attention is paid to the pattern of secondary infections in patients with HIV2 disease.
METHODES: All cases suspectical of having AIDS, AIDS selected complex on progressive generalised lumphodepathy were enclosed in the study. Seaological diagnosis was made by. Hardard methods priorier tested in our laboratory. Primary sceening users wellocozyme 1 and 2 tests. Positive HIV1 is confirmed using seaodiagnostic gel agglutimation test (Fujinibio) and positive HIV2 by Elania II. When concordant test for me or both Viauses are made.
RESULTS: At the total number of HIV seropositives studied 26% ARE, 2% PGL, 5% tuberculosis. The main clinical manifestations of HIV2 disease include wight loss 100%, pynexia 93% oral thoush 71, chronic diarrhoeas 64%, chronic cough 50% and neurologicaloynitons 43%.
HIV2 exerce mortality and morbidity similar to HIV1. There is evidence of vertical transmission.

T.B.P.363

CLINICAL EVOLUTION OF 377 CASES OF LAS/ARC (FOLLOW - UP SINCE 6 - 48 MONTHS)

Ranieri, Sergio *; Nicolli, F.*; De Donà, D.*; Bassi, P.*; Ballardini, G.*; Barelli, A.*.
* Infectious Disease Division; Ravenna S. Maria delle Croci Hospital, Italy.

Objective. The incidence of progression to AIDS of 377 patients with LAS/ARC (334 drug-addicts 2 drug-addicts and prostitutes, 14 homo/bisexual men, 3 homosexuals and drug-addicts, 10 haemophiliacs, 9 heterosexual contacts of drug-addicts HIV-Ab+, 4 individuals with no know risk factors and 1 subject infected through blood transfusion) - followed - up since 6-48 months in the Infectious Disease Division of Ravenna Hospital (Italy) - is reported.

Results and conclusion. The incidence of progression to AIDS of 377 patients with LAS/ARC has been observed in 34 cases (9%), but, the incidence of progression to AIDS results to be 11,4% if we add up the 9 cases of AIDS hospitalized (at the same time) without previous observation and might reach the percentage of 22,5% if we also consider the 42 patients with LAS/ARC affected by minor infections (condyloma, herpes-zoster, thrush, seborrhoea) which have an adverse prognostic significance (Klein e Coll., 1984).
Among the laboratory data with adverse prognostic significance we remark a progressive decrease of CD4 and CD4/CD8 ratio, besides a progressive decrease of total T-lymphocytes.

T.B.P.364

CLINICAL AND EPIDEMIOLOGICAL SPECTRUM OF AIDS DISEASE IN RIO DE JANEIRO, BRAZIL

Serrano, AB*; Ismael, C**; Quinhoes, Eleonora P**; Ramos Filho, CF*; Perez, MA*; Weniger, BG***; Morais de Sá, CA**; Loures, LAM****; Krebs, JW***; and the Clinical AIDS Study Group.
*Hosp Universitário, Univ Fed do Rio de Janeiro (RJ); **Hosp Gaffrée e Guinle, Univ do RJ; ***Centers for Disease Control, Atlanta, USA; ****Ministry of Health, Brazil.

Objective. To determine the clinical presentation—symptoms, signs, and diagnoses—of HIV+ and HIV- patients in order to provide an empirical basis for revision of the national case definition for AIDS surveillance in Brazil.
Methods. All consenting adults (n=496) admitted to medical wards of two large hospitals from 10-12/1988 were tested for antibody to HIV-1 and HIV-2. For epidemiological analysis, patients with ≥2 gene products on either Western blot were considered HIV+. MD interview, physical exam, and chart review were performed on 96% (110/115) of HIV+ patients, and a random sample (n=135) of 365 HIV- patients (16 were excluded for equivocal Western blots).
Results. The HIV+ mean age was 37y, compared to 51y ($p<.001$) for HIV-'s. Males were 94% (103/110) of HIV+'s, but only 50% (67/135) of HIV-'s. Death ensued in 39% (43) of HIV+'s, and only 6% (8) of HIV-'s. PCP was diagnosed in 28% (31) of HIV+'s, cerebral toxoplasmosis in 25% (28), and KS in 11% (12). Major findings predictive ($p<.05$) for HIV+ (other than known AIDS diseases) were oral candidiasis (relative risk [RR]=22.9, predictive value positive [PVP]=86%), fever (RR=18.4, PVP=43%), any tuberculosis (RR=5.1, PVP=61.3%), cotton-wool retinal spots (RR=4.2, PVP=94%), interstitial infiltrates on x-ray (RR=3.9, PVP=80%), and seizures (RR=3.7, PVP=73%). HIV+ patients lost a mean of 21% body weight; HIV-'s only 15% ($p=.001$). No associations of HIV with tropical diseases were found.
Conclusions. With appropriate statistical analysis, easy-to-detect signs and symptoms can be included in a case-definition algorithm for epidemiologic surveillance of AIDS.

T.B.P.365

AIDS ASSOCIATED GLOMERULOPATHY:LUIZ PAULO J. MARQUES,OMAR R. SANTOS,GUILHERME S. LOPES, CARLOS A. BASILIO DE OLIVEIRA, ALBANITA V. OLIVEIRA, LILIMAR S. RIODJA (CLINICA MEDICA III-ESCOLA DE MEDICINA E CIRURGIA, UNI-RIO,BRASIL).

OBJECTIVE:To demonstrate the presence of glomerulopathy in HIV-infected patients.
METHODS: We study 303 HIV-infected patients. The risk factors for HIV were:221 homossexuals; 37 hemophiliacs; 14 unknown; 13 heterossexual contacts; 12 blood transfusions;6 IV drug addicts.
RESULTS: We found nephrotic syndrome in 3 (0.9%), associated with asotemia in 2 (moderate in 1 and severe in 1).Renal biopsy showed focal and segmental glomerulosclerosis (FSGS) in 2 and diffuse glomerulosclerosis in 1. In another patient with proteinuria= 1g/24h and moderate asotemia, renal biopsy showed focal mesangial proliferation and severe interstitial nephritis. Post-mortem renal histopathology in 41 showed mesangial proliferation (MP) in 19(focal in 16 and diffuse in 3), associated with the presence of mesangial fucsinophil deposits, FSGS in 4 and membrano-proliferative glomerulonephritis in one.
CONCLUSION: 1-AIDS-associated glomerulopathy with clinical manifestation was rare(1.3%), probably due to the epidemiologic profile in this series (no Haitian, few heterossexual contacts and IV drug addicts); 2- Subclinical FSGS and MP,the latter possibly due to opportunistic infection or HIV infection, were common features.

T.B.P.366

CERVICAL LESIONS AND HIV INFECTION IN A COHORT OF PROSTITUTES IN KINSHASA, ZAIRE
Nsiangana, Z*; Nelson, Ann Marie**/***; Nzila, N**; Laga, M****; Edidi, B**; Maresila, [illegible]; *Mama Yemo Hospital, Kinshasa; **Projet SIDA, Kinshasa; ***Armed Forces Institute of Pathology, Wash DC; Institute of Tropical Medicine, Antwerp

Objective: To describe the relation of cervical lesions and HIV infection in a cohort of prostitutes in Kinshasa, Zaire.
Methods: Cervical PAP smears were taken as part of the initial work up on 801 prostitutes enrolled in a cohort study in Kinshasa from May to December 1988. Data were collected for age, parity, sexual practices and frequency, duration of prostitution, use of contraceptives and general health. Physical exam, HIV serology, and extensive microbiological studies for concurrent STD's were performed on all women. (A previous study revealed a baseline of dysplasia of 3% in women of the same age from a cohort of HIV negative married couples in Kinshasa).
Results:

RATE OF CERVICAL DYSPLASIA

	<30 YRS	≥30 YRS	Total
HIV +	13/103 (13%)	5/54 (9%)	18/157 (11%)
HIV -	11/160 (7%)	4/58 (7%)	15/218 (7%)

Cytologic evidence of Human Papilloma Virus (HPV) was 11% for HIV+ and 6% for HIV- prostitutes (p=0.1)
Conclusions: 1) Cervical dysplasia is twice as common in HIV+ prostitutes under 30 yrs than their HIV- counterparts (p=0.2). Prostitutes, were 3 times as likely to have dysplasia as women in the general population (p=0.02) 2) HPV infection (by PAP smear) is seen twice as often in HIV+ prostitutes as HIV negative.

T.B.P.368

RELATIONS ENTRE HEPATITE B , INFECTIONS HIVs ET SYNDROME D'IMMUNODEFICIENCE ACQUISE

Ouattara Antoine*, Mélé M**, Gody M***, Manlan LK***et de-Thé G****
*Institut Pasteur de Côte-d'Ivoire,**CHU de Cocody,***Hôpital Protestant Dabou,
****Faculté de Médecine A. Carrel , Lyon , France .

Objectif : Evaluer le risque de portage chronique des infections HBv et HDv chez les porteurs d'anti-HIVs et les relations entre Hépatite B(HB) et SIDA en Côte-d'Ivoire .
Méthodes: 2191 sérums collectés en 1987 dans différents groupes de populations(1126 sujets sains de la population générale , 416 donneurs de sang , 112 porteurs sains d'anti-HIVs ,173 malades atteints de SIDA et 364 malades atteints d'hépatite ictérigène) ont été examinés pour les infections HIV1,HIV2, HBv et HDv .
Résultats: Le portage de l'AgHBs ne variait pas significativement dans la population générale(9,1%) , chez les donneurs de sang(10,8%) et les porteurs sains d'anti-HIVs (13,4%) . Il était cependant plus élevé (p<0,001) chez les malades atteints de SIDA (34,1%) ou d'hépatite ictérigène (40%) . La prévalence des anti-HIVs était de 2,6% dans la population générale, 13,2% chez les donneurs de sang et de 25,5% chez les malades atteints d'hépatite. Toutefois , 10% seulement de ces derniers avaient une HB et 15,6% une hépatite Non-B(HNB) . Une prévalence élevée des marqueurs HDv était observée dans tous les groupes et l'AgHD n'était trouvé que dans les cas d'hépatite ou de SIDA avec une fréquence plus élevée chez les porteurs d'anti-HIVs
Conclusion: Dans cette étude l'immunodéficience induite par l'HIV est probablement responsable de la fréquence élevée de l'AgHBs chez les patients porteurs d'anti-HIVs qui font , par ailleurs , autant de formes d'HNB que d'HB . D'autres études sont nécessaires pour évaluer les interactions entre HIVs et Hépatites Non-A/Non-B particulièrement fréquentes en Côte-d'Ivoire .

T.B.P.369

LYMPHADENOPATHY AND HIV INFECTION.
Basílio, C.A.; Valle, H.A.; Quirinos, Eleonora Pati; Fialho, F.; Sion, F. S.; Morais de Sá, C.A.
Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil.

Objective: To show the histopathological alterations of lymphnodes in HIV infected patients of groups III and IV according to CDC criteria.
Methods: We made a retrospective study of 80 biopsy and 28 necropsy material. We studied only cervical lymphnodes. The staining techniques used were: Hemathoxilin-eosin, PAS, Grocott and Reticulin.
Results:

A - BIOPSY MATERIAL

Type of Lymphadenopathy	N	%
Follicular hyperplasia	46	57.5
Transition	18	22.5
Lymphoid depletion	3	3.8
Mycobacteriosis	6	7.5
Histoplasmosis	2	2.5
Kaposi's sarcoma	4	5.0
Kaposi's sarcoma + Histoplasmosis	1	1.2
T O T A L	80	100.0

B - AUTOPSY MATERIAL

Type of Lymphadenopathy	N	%
Lymphoid depletion	12	42.9
Mycobacteriosis	10	35.7
Histoplasmosis	2	7.1
Criptococcosis	2	7.1
Cytomegaloviruses	1	3.6
Kaposi's sarcoma	1	3.6
T O T A L	28	100.0

Conclusions:
1) The most frequent histopathological aspect of group III patients is follicular hyperplasia

2) The lymphoid depletion was found only among group IV or AIDS patients.
3) Tuberculosis was the most common opportunistic infection.
4) Kaposi's Sarcoma was the only neoplasm we found among the material studied.
5) We did not find Lymphoma.

T.B.P.370

THYMIC PATHOLOGY IN PEDIATRIC AIDS
Grecu, R. Allan*; Thomas, P.*; Kalnowski, V.**; Ragid, R.**; Kahn, E.**; Anderson, V.*. *New York University, NY, NY, **Childrens Hospital, LA, CA, *Cornell Medical Center, NY NY, *North Shore University Hospital, Manhasset, NY, *Pediatric AIDS Study Group, USA

Objective. A variety of thymic lesions have been reported in AIDS. This more detailed and systematic description expands the previous reports.

Methods. We examined the thymuses of 19 infants and children with AIDS aged 2.5 mos to 5.5 years, at autopsy. One infant had a normal thymic shadow on chest roentgenogram at 4 mos.

Results. The thymus was grossly identified in 16 cases. Thymic weights were recorded in 11. They ranged from 4-75% of expected weight for age. No weight was available for 5 thymuses which were described as small. Microscopic findings are shown in the following table:

Sclerosis		Fatty Infiltration	Hassall's corpuscles				Epithelial Network	Thymocytes	Giant cells
Peri-lobular	Intra-lobular		Normal	Rudimentary	Cystic	Calcified			
15	17	13	8	10	3	14	19	16	6

Shrunken lobules, absent corticomedullary demarcation and profound depletion of thymocytes and Hassall's corpuscles were seen. All thymuses contained a densely packed epithelial network composed of varying amounts of spindle and/or epithelioid cells. Stromal (polykaryocytes) and epithelial multinucleated giant cells were seen in 6 cases. Perilobular and intralobular sclerosis, often perivascular, was striking. Abundant thick walled blood vessels of variable diameter were present.

Conclusion. Thymic involution in children with AIDS appears to take place after birth. Their thymuses show a consistent histologic pattern of severe sclerosis. These findings may reflect direct HIV damage of both T cells and the epithelial microenvironment.

T.B.P.371

DELAYED HEALING OF INFECTIOUS SYPHILITIC LESIONS IN HIV-INFECTED ZAMBIAN MEN RECEIVING APPROPRIATE PENICILLIN TREATMENT.

Subhash K. Hira*, Mwendasilumba, D.*, Macauca, R.*, and Perine, P.L.**
*University Teaching Hospital, Lusaka, Zambia, **Uniformed Services University of the Health Sciences, Bethesda, Maryland, United States

Twenty-two men with darkfield-confirmed primary or secondary genital syphilis were followed at weekly intervals to determine their response to treatment with 2.4 mega units of benzathine penicillin IM; seven had HIV infections confirmed by Western blot. Darkfield exam of lesion exudate was done on lesions persisting for more than 1 week post-therapy. Lesions had healed by two weeks in all but two HIV(+) men who had persistence of motile, morphologically typical spirochetes in their lesions at 6 weeks post-therapy, which stained brilliantly with fluorescein conjugated anti-T. pallidum rabbit antibody. Both men denied sexual reexposure and were given two additional weekly injections of 2.4 mega units of benzathine penicillin before they were lost to followup. The persistence of T. pallidum in genital lesions of HIV(+) men may reflect inadequate penicillin dosage, reinfection, or possibly, a selective, HIV mediated immune deficiency to T. pallidum.

T.B.P.373

ETUDE DES MANIFESTATIONS DERMATOLOGIQUES DES SEROPOSIFS HIV_1 HIV_2

NDIAYE B. MBOUP S. GUIRAUD M. KANE A., DIENG M.T.
Université de Dakar, Dakar, Sénégal

OBJECTIF: Discuter les manifestations dermatologiques pouvant conduire au diagnostic d'une infection retrovirale et comparer la fréquence des signes cutanés chez les HIV_1 et HIV_2.

METHODE: Par une étude retropective, nous étalissesons la fréquence des différentes atteintes cutanéo-muco-phanériennes chez les séropositifs. L'étude a porté sur la période allant de Janvier 1986 à Décembre 1988. Elle concerne les malades suivis au service de Dermatologie du C.H.U. Le Dantec de Dakar.

RESULTAT: De 1986 à 1988, huit malades séropositifs ont été observés dans le service de Dermatologie. Les manifestations dermatologiques sont les suivantes: Kaposi, Dermite séborrhéique, Fiessenger-Leroy-Reiter, Syphilis III, Condylome geant, Tuberculose cutanée. Le faible échantillon ne permet pas d'affirmer une correlation significative entre les sérotypes et les lésions cutanées mais restent à être explorée dermatologiques de HIV_1 et HIV_2 semblent identiques. En dehors du carcome de Kaposi et de la candidose buccale classiquement retrouvée dans le SIDA, la découverte de dermatoses tels que le syndrome de FISSENGER-LEROY-REITER, la dermite séborrhérique profuse et les condylomes vénériens peuvent signaler le besoin de rechercher le diagnostic.

Mots clés: Dermatose - SIDA- HIV_1- HIV_2.

GASTROINTESTINAL KAPOSI SARCOMA IN AIDS - ENDOSCOPIC FINDINGS

Heise,Walter,Mostertz,P.,Skörde,J.,Nehm,K.,Grosse,G.,L'age,M.
Auguste-Viktoria-Hospital,Berlin,West Germany
II. Department of Internal Medicine,Department of Pathology

Objective: Frequency and distribution of gastrointestinal (GI) Kaposi sarcoma (KS) lesions,clinical sequelae and the value of endoscopic forceps biopsy shall be discussed.

Methods: In a prospective study,endoscopies of the upper and lower GI tract were done in 17o AIDS patients with GI symptoms.39/17o (23%) had skin KS. Biopsies were taken when cutaneous KS was known or suspicious GI lesions were seen.

Results: KS of the GI tract was found in 46/17o symptomatic AIDS patients. 28/39 (71%) patients with cutaneous KS presented with GI manifestation of KS.In 6 patients KS was found endoscopically without any cutaneous lesion. 28/46 (61%) had visible lesions that were typical for KS.Lesions appeared either macular with submucosal growth or nodular.Gastrointestinal KS was seen more often in stomach and duodenum than in small or large bowel, multiple KS lesions more often than single lesions.Clinical sequelae of proven GI Kaposi sarcoma were not seen.Biopsy was positive only in half of the cases.

Conclusions: Gastrointestinal KS in an important and frequent tumour manifestation in AIDS. 71% of all AIDS patients with GI symptoms and cutaneous KS had GI tumour manifestation.Clinical sequelae are not common. Because of submucosal KS growth biopsy is positive in only 5o% .

T.B.P.372

DERMATITIS OF THE FACE AND YELLOW TOE NAIL CHANGES INDICATE PROGRESSION TO AIDS/OI IN PATIENTS WITH HIV INFECTION

Morfeldt-Manson, Linda *; Julander, I. * and Nilsson, B. **
*Karolinska Institute, Roslagstull Hospital, Stockholm, Sweden, ** Karolinska Institute, Radiumhemmet, Stockholm, Sweden.

Objective. To verify that seborrheic-like dermatitis of the face (DF) and yellow toe nail changes (YN) are clinical signs of deterioration in patients with HIV infection.

Methods. 77 consecutive patients with HIV infection and PGL were studied with regard to the presence/absence of DF and YN at the point of 30 months after diagnosis. The time from 30 months of observation to AIDS/OI or to a T helper cell count $< 200 \times 10^6/l$ was estimated for the patients with the respective sign and compared to the patients without the studied signs. Life table analysis was applied to data. AIDS/OI and T4 cells < 200 were counted as events instead of "death" in ordinary life table analysis. Differences in time to AIDS/OI and T4 < 200 were tested with log rank test.

Results. Time to AIDS/OI or T4 cells < 200 was significantly shorter for the patients with DF ($p << 0.001$) and for the patients with YN ($p < 0.001$) compared to the corresponding time for patients without any of the studied signs.

Conclusion. Seborrheic-like dermatitis of the face and yellow toe nail changes, frequently seen in patients with HIV infection, are clinical indicators of progression to AIDS/OI.

T.B.P.374

CLINICAL MANIFESTATIONS IN AFRICAN CHILDREN PERINATALLY INFECTED BY HIV AND AGED 5 YEARS OLD OR MORE.

Lepage, Philippe*; Van de Perre, P.; Hitimana, D. G.*; Van Goethem, C.*, Kestelyn, P. and Nsengumuremyi, F.
*Department of Pediatrics and ***Department of Ophthalmology, Centre Hospitalier de Kigali, Programme National de Lutte contre le SIDA, Kigali, Rwanda.

Objective: To describe the clinical features of perinatally HIV-infected Rwandese children surviving over 5 years of age.

Methods: Sixteen HIV-seropositive children born to HIV-infected mothers, aged 5 to 12 years old (9 girls and 7 boys; mean age 6.5 years) and diagnosed between 1984 and 1987 in Kigali, Rwanda, were studied. None of these children had received blood transfusions before the onset of HIV-associated symptoms.

Results: These 16 patients represented 3% of the total cases of HIV-infected children (n= 537) diagnosed during the study period.

Two subjects were asymptomatic. Symptoms observed were: Chronic cough (7/16) and chronic diarrhea (1/16). The most common signs were: chronic parotitis (8/16), persistent generalized lymphadenopathy (PGL 7/16), pulmonary tuberculosis (4/16), chronic otitis media (2/16), clubbing of the digits (2/16), herpes zoster infection (2/16), chronic urticaria (1/16) and recurrent seizures (1/16).

Persistent oral trush was not diagnosed. Lymphoid interstitial pneumonitis was diagnosed on radiological grounds in 5/16 patients. Evidence of perivasculitis in the eye fundus was noted in 3/6 cases.

Seven of the 16 children had low weight-for-age and 12/16 had short stature (< 5th percentile of the NCHS standards). Only the 2 symptom free children had normal weight and height for age. Four of the 16 subjects presented with microcephaly.

None of the children died, had life-threatening infection or loss of developmental milestones during the study-period (mean duration of follow-up: 23 months; range: 12 to 39 months).

Conclusion: 1/ Perinatally HIV-infected children surviving over 5 years of age often present with moderate signs and symptoms, principally pulmonary involvement, chronic parotitis and PGL (3 signs characterizing a profuse lymphocytic proliferation).

2/ Severe infections and neurological involvement are uncommon in this age group.

3/ Short stature is a frequent occurence and may be the major clinical manifestation in these patients. Studies are in progress to determine whether this growth retardation is secondary to chronic pulmonary disease or to pituitary deficiency.

T.B.P.376

SEVERE REVERSIBLE GASTROINTESTINAL DILATATION ASSOCIATED WITH HIV1 INFECTION

Victorino Rui; Lucas M.; Neto F. and Moura M.C..
Faculty of Medicine of Lisbon, University Hospital of Santa Maria, Department of Medicine 2, Av. Prof. Egas Moniz, 1600 Lisbon, Portugal.

There is evidence of autonomic nerve dysfunction in patients with HIV infection and more recently extensive damage of the enteric autonomic nerves was documented in patients with HIV associated diarrhea.

We report the case of a patient who presented to an intensive care unit with massive gastrointestinal dilatation and diarrhea and diagnosed as acute pseudo obstruction. Subsequent studies showed that the patient had antibodies to HIV1 on Elisa and Western blot in three different samples. Immunological studies showed hipergamaglobulinemia (2.4gr%), CD4 positive lymphocytes = 884/mm3, CD8 positive = 1175/mm3, T4/T8 ratio = 0.7, with mitogen responses and skin tests for delayed hypersensitivity to Antigens within normal. There was a progressive response to symptomatic treatment of the pseudo obstruction. Detailed gastrointestinal investigations did not show evidence of any secondary gut infection or mechanical obstruction. Epidemiological and Immunological data favour a recent or an acute infection.

In conclusion, the occurrence of massive gastrointestinal dilatation associated with HIV1 infection (probably recent or acute) in this patient, raise the possibility of this gastrointestinal pseudo obstruction being related to the damaging effects of the virus on the autonomic enteric nerves previously reported by other authors.

T.B.P.377

THE SPECTRUM OF CLINICAL DISEASE AMONG FILIPINO CASES

Ofelia T. Monzon,* V. Basaca-Sevilla,** C. Hayes,** J. Capellan,* C. Manaloto,** M.C. Saniel.*
* Department of Health Research Institute for Tropical Medicine, Philippines
**Bureau of Research and Laboratories, Philippines, and US Namru-2, Philippines

Objective. To determine the spectrum of clinical disease in Filipino AIDS cases.
Methods. The records of cases of AIDS among Filipino patients reported to the Department of Health AIDS Registry and referred to one of the authors were analysed to determine the spectrum of secondary conditions seen.
Results. 11/13 cases of AIDS in Filipinos were available for review. There were 9 males and 2 females between 24 to 70 years old. HIV infection was acquired in another country in 10(90%). Risk factors included homosexual/bisexual practices in 6(45%), contact with prostitutes in another country in 2(18%), blood transfusion received in another country in 2(18%), and a spouse of a foreign national who died of lymphoma 1(9%). Multiple infections were seen in all during the illness. These included PCP (5 confirmed, 3 presumptive); candidiasis(6); M. tuberculosis(5); herpesvirus infections(3); 2 each of M. avium-intracellulare, cryptosporidiosis, and CMV; and 1 each of cryptococcal meningitis, T. trichiura infestation, non-malaria erythrocytic parasitism, M. contagiosum, hairy leukoplakia, Kaposi's sarcoma, and a presumptive lymphoma. Recurrent bacterial infections were also observed: urinary tract infection(3), Salmonella bacteremia(2), skin (1), and sinus(1). HIV dementia was diagnosed in 2. 9/11(81%) have died.
Conclusion. HIV infection is of recent introduction in Asia and the clinical picture of AIDS among Asian patients is just emerging. The variety of infectious conditions seen in the early cases of AIDS in this developing country is a forerunner of the diagnostic and therapeutic difficulties which will arise as the number of cases increase in the setting of limited economic resources. There is also a need to monitor the influence of HIV on endemic disease patterns in this region.

T.B.P.378

INTRAUTERINE HIV EXPOSED CHILDREN - RESULTS OF A FOUR-YEAR PROSPECTICE INVESTIGATION

GROSCH-WÖRNER, Ilse*, KOCH, S.*, VOCKS,M.*, SCHÄFER, A.*, HABERMEHL, K.-O. **, MIELKE,M.*** et al. - *Universitätsklinikum Rudolf Virchow, Kinderklinik/Frauenklinik, Standort Charlottenburg; **Institut für Klinische und Experimentelle Virologie, Freie Universität Berlin; ***Institut für Mikrobiologie, Freie Universität Berlin; Berlin, Federal Republic of Germany.

Objective. To report and discuss results to central questions like the transmission frequency, the difficulties in early and reliable definition of HIV-infection, the duration of latency period, the prevalence of symptomatic HIV-infection and early signs of symptomatic HIV-infection beyond the CDC-classification criteria.
Methods. In Berlin, the longitudinal observation of intrauterine HIV exposed children was begun in February, 1985. The children were examined in accordance with a defined clinical, immunological, and virological program at quarterly intervals.
Results. Up to now, 67 children of HIV infected mothers could be observed from birth. 2 of these children (not HIV associated) have died. Of the 67 living children, 33 are older than 15 months. 16 of these children appear to be HIV infected. Of the 34 children younger than 15 months who appear to be infected, 13 children are classified into class P-0. The transmission rate seems to be 50 %. Of the 17 infected children 4 have become symptomatic, all children within the first year of life. 13 children are clinically and immunologically unremarkable. The oldest infected child is 3 years old. The prevalence of symptomatic HIV infection within the 4-year observation period is thus 24 %.
Conclusions. The transmission rate and prevalence rate of symptomatic HIV-infection are similar the results of other prospective studies. Moreover, it has here been confirmed that intrauterine HIV infected children do not necessarily become ill in the first year of life, but that they can remain symptomless for years. The consequences resulting from this - especially in the social area e.g. kindergarden - will be discussed.

(Supported by BMJFFG (Kapitel 1502, Titel 68503) and [illegible] (Nr. 3-43330-13/7))

T.B.P.379

PNEUMOCYSTIS CARINII PNEUMONIA (PCP) PRESENTING AS CYSTIC APICAL LUNG LESIONS WHILE ON AEROSOLIZED PENTAMIDINE PROPHYLAXIS.

SIEGEL, BARY; Flynn, N.; Martin, W.; Soehn, M.; and Pomerantz, S.
University of California Davis Medical Center, Sacramento, California USA.

We have been "prophylaxing" patients at high risk for PCP for almost 2 years with 300 mg of pentamidine aerosolized via a Respirgard-II nebulizer q 2 weeks. Thus far we have had only two documented cases of PCP. CASE 1 was a 28 year old male who was diagnosed with AIDS secondary to wasting in 3/88. He was in a zidovudine study and pentamidine prophylaxis could not be started until 5-23-88. CXR on 9-6-88 revealed multiple thin cavitary lesions in both lung fields predominantly in the upper lobes, bronchoscopy with BAL was negative for any pathogen. The patient did well clinically until 11/88 when he developed mild dyspnea. He refused workup until 12-5-88. CXR revealed multiple upper and left lower lobe cystic lesions with a partial left pneumothorax. Bronchoscopy revealed PCP. CASE 2 is a 30 year old male who was clinically diagnosed with PCP in 3/87. He was initially "prophylaxed" with low dose TMP/SMX which was stopped due to rash. He was started on aerosolized pentamidine and zidovudine in 7/87. He developed paraesophageal sinus tract and during the workup of this, apical cystic lesions and a small pneumothorax were found on CXR in 1/89. Bronchoscopy with BAL revealed PCP. These cases suggest that 300 mg of aerosolised pentamidine q 2 weeks may not completely prevent the recurrence of PCP, disease may occur preferentially in the apices of the lungs and it may appear as cystic lesions on CXR.

T.B.P.380

OCCURENCE OF KAPOSI SARCOMA (KS) IN PATIENTS TREATED WITH ZIDOVUDINE (AZT).

Anne Mathieu-Boué, F. Boué, P. Halfon, J.F. Delfraissy.
CISIH, Paris Sud, France.

Among the 135 HIV positive patients treated with AZT in our center, 5 had KS at the initiation of treatment and of the 131 remaining patients, 4 developed KS during therapy :
Patients (pts) : median age was 41 (36-53), 2 were homosexuals, 2 had heterosexual exposure. All had opportunistic infections and no KS when AZT was started. All had low CD4+ cells count : $50/mm^3$ (15-95), p24 Ag was > 100 pg/ml in 2 pts. KS appeared 4,5 months (1-12) after AZT was started. Three pts had several cutaneous tumors and one a visceral (lung) KS. Diagnosis of KS was histologically confirmed in all cases. AZT therapy was maintained in all patients. KS worsened in 3 pts (new cutaneous or visceral lesions, progression of visceral lesions) and KS was stable in 1 pt. Only 1 pt (lung KS) received specific therapy with α IFN (18×10^6 U/day), no clinical response was observed. Up to January 1989, 3 pts had had new O.I. (1 died) and 1 has a stable disease.

Conclusion : these 4 cases raise some doubts about the opportunity : 1) to treat KS with AZT 2) to maintain AZT, in the absence of other indication, when KS appeared.

T.B.P.381

REGRESSION OF KAPOSI SARCOMA AND IMPROVEMENT OF PERFORMANCE STATUS BY A COMBINED INTERFERON ß AND ZIDOVUDINE THERAPY IN AIDS PATIENTS

Brockmeyer, N.H., Hertins, L., Maleßa , R., Biniek, R., Goos, M., University Essen

Eight HIV infected patients with Kaposi sarcoma (KS) (stadium WR6),were treated with human fibroblast interferon ß and zidovudine for a period of four months. KS were histologically verified, and localised at the hard palate, gum, at the plantar side of the feet, abdomen, and on the arms. In the last two months before therapy all patients had lost 4-10 kg of body weight, CD4 cells were 110/µl.
INF-ß therapy was started by administering 10^6 U/15kg b. w. i. v. daily for two periods of 14 d each, with an interruption of 14 d. After the second course we administered a constant dose of 10^6 U/15kgb. w. every third day. Only minimal side effects were observed. Zidovudine(4x200 mg) had been given daily three months before and during treatment with INF-ß.
All patients showed a significant and persistant regression of the number and diameter of KS after the first treatment period. The KS lesions in the mouth and at the plantar side of the feet disappeared, the other lesions became smaller and changed their colour from dark to bright red, similar to the initial stages of KS lesions. There was a weight gain in all patients and a small increase in helper cells to a mean value of 150/µl; the Karnovski index changed from 30-40% to 80%.
Our findings with INF-ß therapy show clearly the effectiveness of INF therapy . Indeed the number and diameter of the KS lesions was definitely reduced and the perfomance status improved.

ENCEPHALITE AIGUE SPONTANEMENT REGRESSIVE REVELATRICE D'UNE INFECTION A HIV-2

Rogez Jean-Philippe*, Ranger S.**, Buffet-Janvresse C.***, Morcamp D.*, Denis F.**, Leroy J.****
*Service de Médecine Interne, CHG Elbeuf, 76500 France. **Laboratoire de Bactériologie-Virologie, CHU Limoges, France. ***Laboratoire de Virologie, CHU Rouen, France. ****Service de Réanimation Médicale, CHU Rouen, France.

Les atteintes aiguës du SNC liées à une infection à HIV-2 sont rares. Deux encéphalites subaiguës ont été décrites, dont l'une de cause inconnue (Clavel, N.Engl.J.Med.,1987,316,1180-85 et Bertherat, 4th Int.Conf.AIDS,1988).
Cas clinique : Un Sénégalais de 45 ans, vivant en France, est hospitalisé en octobre 1987 pour état de mal convulsif. Au réveil il présente une agitation psychomotrice intense avec hallucinations nécessitant la prolongation de la ventilation assistée par trachéotomie durant un mois et demi.
Biologie : Le LCR initial montre 290 leucocytes/mm^3, une protéinorachie à 2,25 g/l. Tous les examens bactériologiques, parasitologiques et virologiques sont négatifs à l'exception d'une sérologie HIV-2 (réactivité gp140, gp105, p68, p26 par western-blot). Une synthèse intrathécale d'anticorps est démontrée. Le nombre de lymphocytes T_4 est de 110/ul. Le rapport T_4/T_8 est de 0,19 et reste toujours bas huit mois plus tard alors que le malade a complètement récupéré et repris son travail sans avoir reçu de thérapeutique anti-HIV.
Conclusion : Il s'agit donc d'une encéphalite aiguë à HIV-2 spontanément régressive.

T.B.P.383

PREVALENCE DES TROUBLES PSYCHIATRIQUES PARMI LES PATIENTS HOSPITALISÉS POUR SIDA.

Zamperetti Marco*;Ferrazzi D.**;Schlacht I.**
Servizio Psichiatrico di Diagnosi e Cura "Origgi I" e Centro di Medicina Comportamentale (Responsabile Prof.G.F. Goldwurm); **Reparto Infettivi Adulti (Responsabile Prof.F. Chiarelli); Ospedale Cà Granda Niguarda,Milano,ITALY.

Objective. Plusieurs auteurs ont trouvé une prévalence des troubles psychiatriques,parmi les sujets infecté de l'HIV à different stade,qui oscille entre le 30% et le 50% selon l'étude. Nous avons voulu vérifier si cette donnée on peut la retrouver aussi parmi nos patients.
Méthodes. Nous avons pris en considération la population des sujets hospitalisés en maladies infectieuses à l'hôpital de Niguarda à cause de l'HIV. Depuis deux ans,parmi ces patients,on a observé la prévalence et les principaux aspects anamnestiques et cliniques des ceux qui avaient présenté des troubles psychiques.
Résultats. Les patients hospitalisés pour SIDA en 19 mois ont été 125,dont 107 (85,6 %)mâles et 18 (14,4 %)femelles;l'âge moyen a été 28,2 a. Parmi les facteurs de risque,l'utilisation des drogues a représenté le 76,2 %,l'homosexualité le 11 %,les transfusions le 8,4 % et les rapports hétérosexuels le 4,2 %. La prévalence des troubles(t.) psychiques a été du 37,6 %(47/125)dont les t.mentaux organiques étaient le 42,6 %(20/47),les t. de l'humeur le 14,9 %(7/47),les t.de l'adaptation le 12,8 %(6/47),les t.de la personnalité le 8,5 %(4/47),les t. d'anxiété le 8,5 %(4/47), les schizophrénies le 4,2 %(2/47) et enfin les t.psycotiques pas classés ailleurs le 8,5 %(4/47).
Conclusions. Notre étude semble confirmer les travaux d'autres auteurs,soit pour la prévalence des troubles psychiques,soit pour le pourcentage des t. mentaux organiques.

W.B.P.1

FLUCONAZOLE THERAPY OF PATIENTS WITH AIDS AND CRYPTOCOCCAL MENINGITIS AND FAILED CONVENTIONAL ANTIFUNGAL THERAPY.

Rubin, Robert*; Robinson PA**; Knirsch AK**; Joseph JA**, *Massachusetts General Hospital, Boston, Ma, USA, **Pfizer Central Research (PCR), Groton, Ct, USA.

Objective. The study evaluates fluconazole (flu) therapy in patients (pts) who failed or could not tolerate conventional antifungal therapy (conv rx) because of its toxicity or serious contraindications.
Methods. Pts were enrolled if they met both of the stringent entry criteria: 1) life-threatening fungal infection; and 2) failure of conv rx to eradicate the infection, or serious antifungal-related toxicity, or contraindication to its use. Requests for enrollment were reviewed by a PCR subspecialist physician. Pts were treated with flu 200 mg/day, and could be increased to 400 mg/day, if they did not initially respond satisfactorily. Evaluations of clinical efficacy, mycology, and drug safety were recorded. We update our experience with cryptococcal meningitis (cryp men) in AIDS pts in this study.
Results. 158 of 231 pts enrolled in the study had AIDS, and 145 had cryp infection. 67 pts had active cryp men (positive CSF culture at entry). 72% had received ≥ 1 gm of amphotericin B, previously; 57% had received 2 gms. 62% of 59 evaluated pts had a satisfactory clinical response and 66.7% of 38 mycologically evaluated pts became CSF culture-negative. 35 pts had inactive infection (negative CSF culture at entry) and have been followed for a mean of 81.9 days, with only two relapses. Of those with no CSF culture taken at entry (37 evaluable pts), 70% had a clinically satisfactory course, and 7/8 have had negative follow-up CSF cultures.
Conclusions. Flu is effective therapy and maintenance of AIDS pts with cryp men who have failed or cannot tolerate conv rx.

W.B.P.2

ITRACONAZOLE IN THE TREATMENT OF CRYPTOCOCCAL MENINGITIS IN PATIENTS WITH AIDS.

De Gans, Jan*; Portegies, P.*; Tiessens, G.**; Eeftinck Schattenkerk, J.K.M.* and van Ketel, R.J.*. *Academisch Medisch Centrum, 1105 AZ Amsterdam, **Vereeniging voor Ziekenverpleging Prinsengracht, Amsterdam, The Netherlands.

Objective. To assess the efficacy and tolerance of itraconazole (ICZ), a new antifungal triazole, in AIDS patients with cryptococcal meningitis.
Methods. Fourteen AIDS patients with cryptococcal meningitis were treated with ICZ. Nine patients (group I) received induction treatment with i.v. amphotericin B and oral flucytosine for six to eight weeks, followed by maintenance therapy with oral ICZ, 200 mg/day. Five patients (group II) were initially treated with ICZ, 200 mg twice a day for six weeks, followed by maintenance therapy with ICZ, 200 mg/day.
Results. Group I: before maintenance treatment with ICZ was started cryptococcal antigen titer (CAT) in cerebrospinal fluid (CSF) ranged from 1:2 to 1:2048 and was negative in one, while all CSF cultures were sterile. CAT declined in four (range 1:8 to 1:128) and became negative in three patients during ICZ therapy (mean follow-up 11 months). In one patient CAT remained negative and one patient refused CSF re-examination. Only one of six patients who died had relapse of cryptococcal meningitis. In this patient ICZ serum levels declined dramatically during carbamazepine therapy. Group II: before ICZ induction treatment CAT in CSF ranged from 1:1 to 1:1024. After induction treatment CAT in CSF was negative in two, increased in one and unchanged in two patients. These last three patients also improved clinically, but CSF cultures remained positive. During maintenance therapy two relapses occurred because of patient failure. A third patient relapsed and showed extremely low ICZ serum levels during phenytoin therapy. In two patients clinical and mycological cure was achieved (follow-up two and 13 months). No side-effects were observed during treatment.
Conclusion. Itraconazole in the treatment of cryptococcal meningitis in patients with AIDS appears effective and is well tolerated. Carbamazepine and phenytoin might lower itraconazole serum levels.

W.B.P.3

PULMONARY INVOLVEMENT IN CRYPTOCOCCOSIS IN PATIENTS WITH AIDS.

Cameron, Miriam, Bartlett, J., Waskin, H., Gallis, H. Duke University, Durham, North Carolina, U.S.A.

Objective. To study the pulmonary manifestations of cryptococcosis in patients with AIDS.
Methods. A retrospective review was performed of patients with both HIV and cryptococcal infection. Twenty-eight patients were identified who met this criteria from 1983 to 1989. Nine patients had definite evidence of pulmonary C. neoformans infection and 3 had presumptive involvement. Eleven of the 12 patients were male. Age range was 30-48 (mean 35). Risk factors for HIV infection included homosexuality (8), IV drug abuse (3) and both (1). Cryptococcosis was the initial AIDS defining opportunistic infection in 6.
Results. Serum cryptococcal Ag titers were 1/16-1/524288 (median 1/8192) while CSF Ag titers were 1/64-1/2048 (median 1/1024). Seven patients with and 1 without pulmonary involvement died as a result of cryptococcosis. Cultures expressed as total C. neoformans positive/total cultures, chest radiographs (CXR) and initial pO_2 (mmHg) are expressed as follows:

Pulmonary	Blood	CSF	pO_2		CXR
5/5 bronchial alveolar lavage	7/9	11/11	range	28-123	11 interstitial disease
2/4 sputum			mean	82	1 pleural effusion
1/2 pleural fluid			median	75	1 adenopathy only
2/2 lung (autopsy)					

Conclusion. Pulmonary involvement with cryptococcosis in AIDS patients is probably more common than previously realized. The CXR most often showed interstitial disease which can be confused with other opportunistic infections such as PCP. Pulmonary involvement with cryptococcosis may be associated with a higher mortality than cryptococcal meningitis alone.

W.B.P.4

PROGNOSTIC FACTORS OF CRYPTOCOCCAL MENINGITIS IN AIDS PATIENTS

Kayembe-Kalambayi M.D.*, P. Desmet**
*Dept. of Internal Medicine, ** Laboratory of Mycology, Cliniques Universitaires de Kinshasa, Zaire.

Aim. Investigate which parameters could be indicative of a good or bad prognosis for cryptococcal meningitis in AIDS patients
Methods. 34 HIV$^+$ patients (21 males and 13 females) with cryptococcal meningitis confirmed by microscopy, antigen determination and Sabouraud culture were followed up at the University Hospital, Kinshasa, between December 1, 1987 and October 31, 1988. Patients were divided into 2 groups; those diagnosed within a delay of 15 days of their clinical symptoms and another group after 15 days or more. Survival rate after diagnosis was analysed with respect to time to diagnosis and to the mycological and serological parameters in blood and CSF.
Results. Mean results are given in the table below.

Delay (days)	n	CSF antigen	Serum antigen	CSF culture$^+$	Blood culture$^+$	Microscopy No./field (FF = 100 x)	Survival (days)
< 15	10	1/840	1/5250	10/10	4/10	5.8	75.8
> 15	24	1/3882	1/26272	24/24	12/19	30	36

Conclusion. Time elapsed between appearance of symptoms and confirmation of diagnosis appears to be the best prognostic factor. The longer the period before diagnosis is confirmed, the more mycological parameters become abnormal and the shorter the survival time. Consequently, systematic screening for cryptococcosis in HIV$^+$ patients seems logical.

W.B.P.5

INTRAVENOUS AND ORAL FLUCONAZOLE (FCZ) FOR THE TREATMENT OF ACUTE CRYPTOCOCCAL MENINGITIS

Wesraf Sanjana,Davidson,M.,Mullen,M.,Boyle,D., Raviglione,M., Cortes,H.,Cabrini Medical Center,New York City, NY USA

OBJECTIVE: To assess the safety and efficacy of I.V. and oral FCZ in the therapy of acute cryptococcal meningitis (ACM).
METHODS: Since 9/88, 7 consecutively diagnosed pts. with ACM were treated with FCZ IV (400 mg loading dose then 200 mg/d) for 2 weeks, then orally (200 mg/d) thereafter.
RESULTS: 6/7 pts. responded. One pt. had seizures & mentally declined (day 2), was switched to conventional tx, and expired. All 6 pts. who received >4 days of FCZ responded clinically and were discharged 18-24 days after starting treatment. 5/6 continue to be ambulatory and without evidence of clinical relapse at 10-18 weeks. However, the most recent CSF cultures are positive for C. neoformans in 4/6 pts. after 6-13 weeks (median 10 weeks) including one pt. whose CSF became negative over a 6 week period (3 specimens), then reverted to positive. This pt. despite escalating FCZ to 400 mg/d subsequently developed a clinical relapse (week 20). No clear relation between clinical remission and cryptococcal antigen titers was evident.
CONCLUSIONS: FCZ at 200 mg/d appears to be highly effective in inducing an initial clinical remission (87%) in previously untreated cases of ACM. No adverse effects were noted that could be attributed to the drug either during the I.V. or the oral phase. At 200 mg/d, however, microbiological cure was achieved in only 3/7 cases within a median follow-up of 10 weeks and one of these 3 had both a microbiological and clinical relapse. Recruitment of pts. continues and longer term follow-up will be presented.

W.B.P.6

SERUM CRYPTOCOCCAL ANTIGEN SCREENING IN THE EARLY DIAGNOSIS OF CRYPTOCOCCAL INFECTION IN PATIENTS WITH HIV INFECTION

Masci, Joseph; Pierone,G.; and Nicholas,P.
Mount Sinai Services, Elmhurst Hospital Center, Elmhurst, N.Y., U.S.A.

Objective. To determine if serum cryptococcal antigen is of value as a screening test for cryptococcal infection in patients with human immunodeficiency virus (HIV) infection.
Methods. Serum cryptococcal antigen tests were performed on 88 HIV infected patients who were felt to be at risk for cryptococcal infection on the basis of T cell subset analysis or prior opportunistic infection. The latex aglutination method was used.
Results. 4/88 patients had a positive test (4.5%). The positive inverse titers ranged from 16 to 2360 (avg 916). 3 of these patients were asymptomatic (one with a lung nodule which resolved on amphotericin B therapy, 2 with culture-positive cryptococcal meningitis). The fourth patient had complaints of fever, cough, and night sweats and was shown to have cryptococcal meningitis despite the absence of specific symptoms. Cryptococcal antigen titers fell significantly and all cultures became negative during therapy with amphotericin B.
Conclusion. Screening HIV infected patients with significant immunodepression with cryptococcal antigen determinations appears to be effective in the early diagnosis of cryptococcal infection.

W.B.P.7 RESPONSE OF CRYPTOCOCCAL MENINGITIS TO ANTI-FUNGAL THERAPY IN PATIENTS WITH AIDS

Nelson, Konrad E., Thaker, G.K., Merz, W., and Bartlett J.G.
John Hopkins Medical Institutions (JHMI), Baltimore, MD.

Objective. To describe the natural history and response to antifungal therapy of cryptococcal meningitis in AIDS patients.
Methods. Medical records were reviewed and follow-up information obtained for all patients with disseminated cryptococcal infections at JHMI between Jan 1, 1985 and May 15, 1988. Patients were characterized by their underlying disease, presenting symptoms, history of other opportunistic infection and laboratory work-up. Therapeutic responses, complications, and survival were analyzed.
Results. 48 pts. had cryptococcal meningitis; 39 had AIDS and 9 had other diagnoses. Patients with AIDS were treated initially with amphotericin-B (AMPHO-B) alone (20 pts.) or AMPHO-B plus 5-fluorocytosine (5FC, 18 pts.). Maintenance therapy with AMPHO-B 1-3 mgm/kg/wk. was usually given by Hickman. Survival curves suggested improved survival with initial AMPHO-B + 5FC therapy (median = 240 days) than with AMPHO-B alone (median = 95 days, Wilcoxan test p = .07). Pretreatment CBC values were not significantly different in the two treatment groups, suggesting the groups were similar at baseline.
Conclusions. Our retrospective data suggest that 5FC may improve survival in AIDS patients with cryptococcal meningitis when added to AMPHO-B treatment, as has been reported in patients without AIDS. A controlled study of this regimen is indicated.

W.B.P.8 SPECTRUM OF CRYPTOCOCCUS NEOFORMANS INFECTION IN 68 HIV INFECTED PATIENTS

Clark, Rebecca*; Greer, D.*; Atkinson, W.**; Valainis, G.*; Hyslop, N.*.
*Tulane/LSU ACTU, **Tulane School of Public Health and Tropical Medicine, New Orleans, LA, USA

Objective. To review the spectrum of clinical features and results of therapy of Cryptococcus neoformans (Cn) infections in HIV infected (HIV+) patients.
Method. Hospital records and X-rays of all HIV+ patients found to be infected with Cn by either microbiological or histopathologic evidence were reviewed retrospectively. All patients were seen at Charity Hospital of New Orleans, Veterans Administration Medical Center, or Tulane Medical Center between January 1,1985 and December 1, 1988 (47 months).
Results. Sixty-eight HIV+ patients were identified. Ninety-eight percent were males and 68% were homosexual/bisexual. Mean age was 32.7 (± 7) years. In 75% (51/68) Cn was the initial opportunistic process and 13% (9/68) had pulmonary involvement only. Extrapulmonary cryptococcosis was found in over 12% of the total number of AIDS cases diagnosed. Patients with positive CSF cultures typically presented with headache (68%) and fever (66%). Cn was isolated from CSF in 51/63, blood 27/40, bone marrow 3/10, and urine 4/7. Common initial therapeutic regimens were amphotericin B (AmB) alone (36%) or AmB plus flucytosine (54%). Sixteen (24%) patients died within the first 14 days. Although overall median survival was 5 (± 1) months, 12 patients (11 CNS) survived at least 12 months. Patients presenting with an abnormal head CT or altered mental status had a shortened median survival.
Conclusions. In New Orleans Cn is a frequent pathogen in HIV+ patients. Mortality remains high with current treatment.

W.B.P.9 FLUCONAZOLE (FLU) TREATMENT OF PERSISTENT URINARY CRYPTOCOCCOSIS (PUC) AFTER CRYPTOCOCCAL MENINGITIS (CM).

Bozzette, Samuel A, Larsen, RA; Chiu J; Leal ME; Large K; and McCutchan JA. UC San Diego, U Southern Cal, UC Irvine and The California Collaborative Treatment Group. U.S.A.

Objective: To study the response of PUC to FLU. PUC occurs in up to 30% of AIDS patients successfully treated for CM, is usually localized in the prostate, appears to resist further amphotericin B (AB) therapy, and is probably associated with relapse of CM.
Methods: Thirteen patients who completed standard therapy for CM (median ampho B dose: 1624 mg; median 5-FC duration: 7 wks) were treated with FLU at 100 to 400 mg/day. Response was defined as suppression of post-prostatic massage (PPM) cryptococcuria and extra-urinary tract disease as determined by monthly PPM urine and blood cultures and by serum antigen titers. CSF examinations were performed as clinically indicated.
Results: Six of 13 (46%) patients had their PPM urine sterilized beginning at 1 to 16 (mean 7) weeks of treatment. Seven (54%) had persistent PPM cryptococcuria over 4 to 51 (mean 22) weeks of treatment. Two (15% overall) of these 7 developed recurrent meningitis at 6 and 22 weeks. Serum antigen rose ≥ 4-fold in these 2 and in 3 other patients. The probability of response was .15 at 2 wks, .32 at 6 wks, and .59 at 14 wks and thereafter. No patient developed cryptococcemia or FLU toxicity.
Conclusion: Treatment of PUC with FLU is well tolerated, suppresses funguria in about 1/2 of patients, and may reduce extra-urinary relapses. CM recurs in some patients whose funguria is not suppressed. Cure cannot be evaluated since all successfully suppressed patients have continued FLU.

W.B.P.10 THERAPY (RX) OF CRYPTOCOCCAL MENINGITIS (CM) AND CRYPTOCOCCOSIS (C) IN AIDS WITH ORAL ITRACONAZOLE (IZ).

Denning, David W; Tucker, RM; Hamilton, JR; Hanson, LH; Stevens, DA.
Santa Clara Valley Med. Ctr., Stanford Univ., Institute Medical Research, San Jose and Stanford, CA. U.S.A.

Objective. Despite poor CSF penetration, IZ is efficacious in CM models; we studied its efficacy in man as sole therapy.
Methods. We studied clinical, culture, serological responses to IZ (400mg/d) in 24 patients (pts) with AIDS: 18 with CM, 13 with cryptococcemia (CB), 5 with cryptococcuria (UC) and 3 with pulmonary disease (PC); 16 pts had multiple sites of disease. Four pts had failed and 3 had relapsed after previous therapy; 17 pts sought oral Rx.
Results. CB was abolished in 10 of 10 (100%) evaluable pts; 2 non-compliant pts relapsed. Ten of 14 (71%) evaluable CM pts had a complete response (clinical resolution with negative CSF cultures), 3 of 14 (21%) a partial response (clinical improvement with positive CSF cultures) and 1 (7%) failed Rx; 4 CM pts were unevaluable (<2 weeks Rx). Partial response and failure were associated with failure of previous Rx, low (<1.0 mcg/ml) serum IZ concentrations and severe disease. Among CM responders 3 of 13 (23%) had recrudescence of CM on Rx. Two evaluable pts with PC responded (100%). UC was abolished in 3 of 5 (60%) pts. Steady state mean serum IZ levels ranged from 0.43 to 8.0 mcg/ml (mean 3.36 mcg/ml). Toxicity was seen in 7 pts and was self-limited and mild in 6; one developed hypertriglyceridemia and pancreatitis. Forty of 44 isolates were susceptible (≤3.13 mcg/ml) in vitro to IZ; 3 borderline; 1 resistant.
Conclusion. IZ is effective in CM and C as primary or salvage therapy.

W.B.P.11 PERSISTENT Cryptococcus neoformans PROSTATIC INFECTION AFTER SUCCESSFUL TREATMENT OF MENINGITIS.

Robert Larsen, S Bozzette, JA McCutchan, J Chiu, M Leal, D Richman. California Collaborative Treatment Group, USA.

Objective: To assess the frequency of persistent C. neoformans infection in patients with AIDS after receiving apparently adequate treatment for meningitis.
Methods: All patients had AIDS and C. neoformans meningitis. Therapy consisted of either 2.0 grams of amphotericin B alone, or an adjusted minimum amphotericin B dose if combined with flucytosine. Two successive culture negative CSF samples were needed to meet criteria for adequate treatment of meningitis.
Results: Urine cultures obtained at the end of treatment grew C. neoformans in 9 of 41 (22%) patients. All were asymptomatic. Fungi were visualized in expressed prostatic secretions in 3 of 9 and grown only from post-prostatic message urine in 4 of 9 patients. Three patients received additional amphotericin B; all had persistent funguria without systemic relapse. Of 6 patients on fluconazole; 4 became urine culture negative and 2 had systemic relapse during therapy. One patient refused treatment and developed cryptococcemia at 5 weeks.
Conclusion: The persistence of urinary infection with C. neoformans in spite of adequate therapy for meningitis suggests that the urinary tract (probably the prostate) is a sequestered reservoir of infection. Patients with AIDS and persistent urinary cryptococcosis maybe more likely to relapse.

W.B.P.12 EFFICACITE DU FLUCONAZOLE COMPAREE AVEC AMPHOTHERICINE B PLUS 5 FLUCYTOSINE DANS LE TRAITEMENT INTENSIF ET DE MAINTIEN DE LA CRYPTOCOCCOSE MENINGEE ASSOCIEE AU SIDA.

Kahotwa, M.*; Kapila, Bila**; Colebunders, R.*; Mungieri, A.; Perriëns, J.*. *Projet SIDA, **Hôpital Mama Yemo, Kinshasa, Zaire.

Objectifs. 1. Comparer l'éfficacité du fluconazole (F) avec celle d'amphothericine B (A) plus 5 flucytosine (5FC) dans le traitement (TTT) inital intensif de la cryptoccose méningée (CRM). 2. Evaluer l'éfficacité du F dans le TTT de maintien de la CRM.
Méthodes: Étude prospective controlée, dans laquelle 36 patients (pts) avec CRM ayant un contact verbal preservé ont été randomisés pour recevoir soit F (400 mg/j PO), soit A (0.3-0.6 mg/kg/j IV) + 5FC (150 mg/kg/j PO) pendant 6 semaines comme TTT initial, suivi de F (200 mg/j PO) comme TTT de maintien. Les pts ont été suivi par un controle clinique, un examen microscopique et de culture du LCR à 4 et 6 semaines après le debut du TTT, et puis tous les mois.
Résultats. 1. TTT initial:

		A+5FC (n=18)	F (n=18)
MICROSCOPIE LCR NEGATIVE	à 4 semaines	3/14(21%)	4/ 8(50%)
(sur examens effectués)	6 semaines	2/ 9(22%)	2/ 9(22%)
CULTURE LCR NEGATIVE	à 4 semaines	12/14(86%)	7/ 8(88%)
(sur examens effectués)	6 semaines	8/ 9(89%)	4/ 9(44%)
MORTALITE	à 4 semaines	4/18(22%)	4/17(24%)
(sur nombre de pts suivis)	6 semaines	7/16(44%)	8/17(47%)

2. TTT de maintien: 2 moribonds (TTT F), 1 moribond (TTT A+5FC), et 1 résistant au TTT F, tous LCR microscopie (+) et 3 avec LCR culture (+), n'ont pu être mis sous TTT de maintien. Nous n'avons observé aucune récidive de CRM chez les 14 pts, tous LCR culture (-) au début du TTT de maintien sous F. Leur mortalité reste élevée: 6/14 décédés après un follow-up de 110 jours en moyenne (range 45-270 jours). Le suivi des 8 survivants s'étend sur 185 jours en moyenne (range 90-375 jours). Le TTT initial n'avait aucune influence sur la mortalité en phase de maintien.
Conclusions. Le F peut être utilisé avec succes dans le TTT initial intensif de la CRM et dans le TTT de maintien. Nos donnees limitees devraient cependant etre confirmees dans de plus grandes etudes.

W.B.P.13

LE "FLUCONAZOLE" DANS LE TRAITEMENT DE LA CRYPTOCOCOSE MENINGEE CHEZ LES PATIENTS ATTEINTS DE SIDA.

KAVEMBE KALAMBAYI*, MD et DESMET P.**
* Cliniques Universitaires de Kinshasa, **Labo de Mycologie.
Zaïre.

Objectif: Etudier cliniquement l'efficacité du Fluconazole dans le traitement de la cryptococose meningée chez les sidéens.
Patients et méthodes: 34 cas HIV+ (21♂ et 13♀) avec cryptococose meningée confirmée par culture (Sabouraud) et par sérologie (Kit IMMY) ont été traités de façon randomisée soit par fluconazole soit par association Amphotéricine B + 5 fluorocytosine. Etaient considérés comme guéris cliniquement ceux dont les symptômes cliniques disparaissaient et guéris mycologiquement ceux dont la culture du liquide céphalo-rachidien (Lcr) devenait négative après 2 contrôles successifs.
Résultats: 17 malades ont eu le fluconazole (groupe A) et 17 l'association amphotéricine B+5 fluorocytocine (groupe B).

Moyennes	Gr A	Gr B	
Durée des sympt.avant le dx	40jrs	44jrs	p=0,7
Ag Crypt. dans le sang	1/25332	1/14047	p=0,6
Ag Crypt. dans le Lcr	1/2184	1/3806	p=0,3
Survie	57jrs	37jrs	p=0,2
Guérison clin.	11/17	3/17	
Guérison myc.	5/17	3/17	

Conclusion: Le fluconazole a une efficacité comparable à celle de l'association amphotéricine B + 5 fluorocytocine.

W.B.P.14

LA CRYPTOCOCCOSE AU BURUNDI

FLOCH Jean-Jacques, DEPPNER R., LAROCHE R., KADENDE P.*
*Centre Hospitalo-Universitaire de Bujumbura/BURUNDI.

OBJECTIF : Montrer l'importance de la méningite à cryptocoques dans le SIDA et l'intérêt de son traitement par le FLUCONAZOLE.
METHODE : - Etude de 31 cas de méningites à cryptocoques observées en 32 mois à Bujumbura au cours de SIDA confirmés sérologiquement (ELISA, WESTERN-BLOT)
- Diagnostic clinique et diagnostic biologique reposant sur la mise en évidence de levures typiques de Cryptococcus néoformans variété Gattii par examen microscopique direct du L.C.R. avec mise en culture systématique sur milieu de Sabouraud suivi d'une identification mycologique précise. - Traitement après tirage au sort, faisant appel :
. à association amphotericine B et 5 fluoro-cytosine . ou au FLUCONAZOLE.
RESULTATS : - Fréquence de la cryptococcose dans le SIDA : 14 % des cas
- Symptomatologie : méningo encéphalite dans 80 % des cas
- Traitement par FLUCONAZOLE très prometteur, efficace, bien toléré, facile à administrer

CONCLUSION :
La Méningite à Cryptococcus néoformans variété Gattii est fréquente dans le SIDA au Burundi. Son diagnostic est facile. Le traitement par le FLUCONAZOLE est très prometteur, efficace, d'administration facile, bien toléré, bien adapté aux pays à niveau sanitaire insuffisant.

MOTS-CLEFS :
Méningite, Cryptocoques, S.I.D.A.

W.B.P.15

CRYPTOCOCCAL DISEASE AND HIV INFECTION IN NORTH CAROLINA

Waskin, Hetty, Bartlett JA, and Gallis HA
Duke University Medical Center Durham, North Carolina USA

Objective: Evaluate characteristics of cryptococcal disease among persons with human immunodeficiency virus infection in rural, southeastern USA.
Methods: A retrospective review of clinical and laboratory records.
Results: From 1985 through 1988, the proportion of patients with cryptococcal disease who also had HIV infection tripled:
1985- 26% (5/19), 1986- 23% (3/13), 1987- 67% (10/15), 1988- 73% (11/15)
We compared the 29 HIV+ patients to the 33 HIV- patients diagnosed with disseminated or meningeal cryptococcosis. HIV-infected patients were more likely to have cryptococcal meningitis, had rapid conversion of serum antigen titers from negative to positive, and had higher cryptococcal antigen titers at the time of initial diagnosis.
A review of survival trends of the HIV-infected cohort (n=29) indicated that: 12-month survival following diagnosis has increased from 13% (1/8) in 1985-1986 to 67% (6/9) in 1987-1988. The magnitude of titratable antigen (by latex fixation) at the time of diagnosis was not predictive of long-term response. Two of the 7 long-term survivors had initial CSF antigen titers greater than 1:1000; one patient had a CSF titer greater than 1:1000,000.
In all patients, a decline in cryptococcal antigen titer did occur following initiation of therapy and was associated with a positive response. Subsequent increase or plateau of antigen levels was associated with relapse. All long-term survivors required maintenance therapy.
Conclusion: The diagnosis of cryptococcosis in HIV-infected patients should not confer a dismal prognosis.

W.B.P.16

CRYPTOCOCCAL MENINGITIS IN PATIENTS WITH AIDS. DIAGNOSTIC FEATURES AND OUTCOME IN 8 CASES.

Antonucci,G.*;Armignacco,O.*;Ippolito,Giuseppe*;Bordi,E.*;
Galgani,S.**;Grillo, LR**.
*Lazzaro Spallanzani Hospital for Infectious Diseases,Rome,Italy
**S.Camillo Hospital,Rome, Italy.

Objective. To study clinical and laboratory features of cryptococcal meningitis (CM) in patients (pts) with AIDS.
Methods. Investigations involved clinical manifestation,tests on blood, CSF, other fluid and tissues, CT brain scans and/or cranial MRI.
Results. Among 101 patients with AIDS observed from 1984 to 1988, 8 (7.9%) had CM. Four of them had also extraneurologic involvement. CM was the first diagnosed opportunistic disease in 6 pts . Fever and headache were present rispectively in 87.6% and 75.0% of pts.Alterations of mental status,meningismus and vomiting occurred in 62.5%, 37.5% and 25% respectively.The symptoms duration before diagnosis ranged from 8 to 20 days. The diagnosis of CM was based on CSF studies in 7 cases and on autopsy findings in one.The range of CSF proteins was 25-172 mg/dl,the glucose range was 16-60 mg/dl and the white blood cell count was normal in only 1 of 7 pts (range 3-80 cells/ml). The CSF culture was positive in 4 pts, Indian ink preparation in 6 of 7 pts and the cryptococcal antigen titer was positive in all pts. CT brain scans and/or MRI revealed abnormal results in 6 pts.
Therapeutic regimen included amphotericin B 0.3 mg/Kg plus flucytosine 150 mg/Kg die. Two of the 7 pts were cured.
Conclusions. The Authors point out that CM may present in an indolent manner in pts with AIDS,the high mortality rate in spite of an early diagnosis and the recommended therapeutic regimen.

W.B.P.17

THE LIMITED VALUE OF ROUTINE SERUM ANTIGEN SCREENING FOR CRYPTOCOCCAL INFECTION.

NELSON MARK.R. SMITH D.E. HAWKINS D. SHANSON D. REED C.
GAZZARD B.G. ST STEPHENS HOSPITAL, FULHAM ROAD ,LONDON
ENGLAND.

OBJECTIVE: To assess the routine serum cryptococcal antigen as a screening procedure for diagnosis of cryptococcal infection.
METHOD: All HIV Antibody positive patients over a three year period who had pyrexia of unknown origin or meningism underwent screening by serum cryptococcal antigen latex agglutination test. All patients with a positive titre or signs of meningism had a lumber puncture. In those patients with a positive serum antigen, a further antigen was performed on serum saved prior to diagnosis.
RESULTS: Only 15 of 828 serum cryptococcal antigens were positive, 13 of whom had meningism and had cryptococcal meningitis confirmed at lumber puncture. The other 2 patients had pyrexia of unknown origin without meningism and had no CSF abnormality. One has remained well for over one year. The other had a fungaemia which responded to conventional therapy and is well at six months. Saved serum was available on 8 of the patients with positive serum antigen within 3 months prior to diagnosis (range 30-90 days: mean 60 days). All were well at time of testing. None of the sera were positive.
CONCLUSION: Cryptococcal antigen testing is not of value as a screening test for patients with a pyrexia of unknown origin or in predicting which well patients may develop this infection. It does predict which patients with meningism have cryptococcal infection.

W.B.P.18

CRYPTOCOCCUS NEOFORMANS PULMONARY INFECTION IN 17 HIV INFECTED PATIENTS

Clark,Rebecca*;Greer,D.*;Valainis,G.*and Hyslop,N.*.
*Tulane/LSU ACTU, New Orleans, LA, USA

Objective. To review the presentation and clinical course of Cryptococcus neoformans (Cn) pulmonary infections in HIV infected (HIV+) patients.
Method. Hospital records and chest X-rays of HIV+ patients known to have Cn pulmonary infection either by positive respiratory cultures or histopathologic evidence were retrospectively reviewed. All patients were seen at Charity Hospital of New Orleans, Veterans Administration Medical Center, or Tulane Medical Center between January 1, 1985 and December 1, 1988.
Results. Of 17 patients, all were male; most were white (56%), and homosexual (93%), with an average age of 33 (± 6) years. The most frequent presenting symptoms were fever (93%) and cough or dypsnea (57%). Although chest X-ray patterns included cavitary lesions (2), nodules (2), and a solitary lobar infiltrate (1), the most common finding was bilateral interstitial infiltrates (7), of which 3 had coexistent cytologically proven PCP. Positive simultaneous extrapulmonary cultures, CSF (8/15) and blood (4/10), were found in 8 patients. Five patients with no extrapulmonary infection died with a mean length of survival of 16 (± 6) weeks and 6 patients with concomitant CNS involvement died with a mean length of survival of 4 (± 5) weeks.
Conclusions. Chest X-ray findings in HIV+ patients with Cn pulmonary infections can have unusual features and differentiation from PCP may be difficult. The mortality rate is high in HIV+ patients with Cn pneumonia and may be influenced by the presence of CNS involvement.

W.B.P.19 CRYPTOCOCCOSIS IN AIDS PATIENTS: CLINICAL AND THERAPEUTIC ASPECTS.

Weinke,Thomas; Rögler,G; Ortmann,C.; Pohle,H.D..
Universitätsklinikum Rudolf Virchow, Freie Universität Berlin, West-Germany.

Objective. Cryptococcus neoformans is a dangerous pathogen in AIDS patients and usually leads to disseminated disease. Prognosis depends on early diagnosis and early onset of proper treatment. We report an attempt at identifying characteristics that facilitate earlier recognition of cryptococcosis and describe the effectiveness of therapeutic approaches.
Methods. All AIDS patients were screened for cryptococcal antigen in serum; if indicated sputum, CSF, blood, urine and stool were taken for culture on selective media. Clinical symptoms were determined and the response to therapy was judged by means of cultures of the affected site.
Results. 9 out of 184 (4,9 %) patients with AIDS had evidence of cryptococcal disease. 8 patients had disseminated cryptococcosis and cryptococci could be cultured from various body sites; one individual had still localized disease in the lungs. The main presenting features were very unspecific and consisted of headache, fever, and nausea. Laboratory data confirmed advanced immunosuppression (mean CD4-value 42). Meningism and elevated CSF leucocyte counts were present in only three patients. Cryptococcal serum antigen titres correlated with the severity of the disease: One patient with advanced disease and the highest titre (1:100.000) died 3 weeks after onset of treatment. Therapy with amphotericin B and flucytosine over 6 weeks was very effective and 7 of 9 patients were cured. Life expectancy was reduced by other AIDS-related opportunistic infections, since only one patient died because of cryptococcosis.
Conclusion. Routine screening for cryptococcal antigen in HIV-infected persons is essential for early diagnosis of cryptococcosis since clinical symptoms are very subtle. Early diagnosis and rapid onset of therapy improves prognosis. From our experience amphotericin B and flucytosine is the treatment of first choice.

W.B.P.21 THERAPEUTIC STUDY IN 35 PATIENTS WITH AIDS AND CRYPTOCOCCAL MENINGITIS.

Del Bianco,R.; Scapini,R.; Prado,P.S.; Brunetti,G.; Leme,S.S.T.;Mendonça,M.;
Centro de Referência eTreinametno em Aids-Sao Paulo,Brazil
Instituto Adolfo Lutz

Objective.Analysis of the cerebrospinal fluids in 35 patients during therapeutic with Anphotericin B.
Methods. 35 patients were studied from october 86 until november 88 They were treated with AnphB and 5-fluorcytosine was also added in 19 patients(54,3%).The cerebrospinal fluids were obtained from all the patients before and during therapeutic.
Results. The first white cell count was from 0 until 10cell/mm3 in 71,4% patients,proteints 40 mg% in 80% and glucose 40mg% in 51,4%. The first India ink test performed in the patients was positive in 8,5% cases and the culture was negative in 8,5% cases. 45,7% patients had the India ink test negative with a total median dose of 1.200 mg and the culture was negative in 68,5% patients with a total median dose of 977mg. 20 patients(57,1%) died with a total median dose of 1.555mg. The rate of suvival was 5,1 months and the median 4,1 months.
Conclusion. Tge India ink test provided diagnosis in almost all the patients and was more sensitive than the culture to analyse the efficacy of the drugs.

W.B.P.20 CRYPTOCOCCAL MENINGITIS IN AIDS PATIENTS:INCIDENCE IN RIO GRANDE DO SUL(BRASIL)

Kronfeld, Matias+ and Sprinz, E++.
+Universidade Federal,Porto Alegre, Rio Grande do Sul, Brasil.
++Hospital de Clinicas de Porto Alegre(HCPA), Rio grande do Sul, Brasil.

Objective. Establish the incidence of cryptococcal meningitis in Rio Grande do Sul(RS) state.
Methods. It has been reviewed, at random, 80 registers of AIDS patients that have been hospitalized between january and november 1988 at HCPA. In 60 patients al lumbar puncture has been done and the liquor examined with the India ink preparation.
Results. 11 patients had fungal or bacterial meningitis. The India ink preparation was positive in 8 cases(10% of the sample and 72,7% of fungal and bacterial meningitis.
Conclusion. Cryptococcos neoformans is the most common cause of meningitis in AIDS patients in RS state. Therefore, in patients coming from this state, as in other places of the world, it is extremely important to consider criptococcosis as a potential disease of the Central Nervous System.

W.B.P.22 MAINTENANCE THERAPY WITH AMPHOTERICIN B IN AIDS PATIENTS WITH CRYPTOCOCCAL MENINGITIS

B.Clotet,R.Villegas,G.Sirera,M.Dominguez,A.Jou,JM.Gimeno,M.Foz.
Infectious Diseases Unit.Hospital de Badalona "Germans Trias i Pujol".
Badalona.Barcelona.Catalonia.Spain.

Objective: To report the efficacy of amphotericin B and ketoconazole as a maintenance therapy for cryptococcal meningitis in an AIDS patient.
Material: A 25 year-old intravenous drug abuser with antibodies to HIV presented a cryptococcal meningitis and received initial therapy with amphotericin B and flucytosine at a standart dosis for a 4 weeks period and then entered in a maintenance schedule of 80 mg/21 days of amphotericin B plus ketoconazole 400 mg every other day.Follow-up is actually of 14 months and the patient has reassumed a normal life.Cerebrospinal fluid cultures are negative for cryptococcus at a 1 year interval since the initial therapy.
Discussion: Although some patients have a prolonged relapse-free survival in spite of discontinuing maintenance therapy with amphotericin B it appears evident that long term suppressive therapy may offer a more convenient approach in patients with AIDS. Although fluconazole has obtained promissing results,until its availability in all centers different maintenance amphotericin B dosis should be reported if they give new clues for a major compliance.Ketoconazole may eliminate the cryptococcal sources outside the central nervous system that could be implicated in some relapses.

Infections liées au SIDA : toxoplasmose
AIDS Related Infection: Toxoplasmosis

W.B.P.23 TOXOPLASMOSE PULMONAIRE (TP) AU COURS DU SIDA.

Marche Claudie ; Wolff, M ; Mayorga R ; Matheron S; Salmon D.
Matthiessen L ; Claude Bernard , Paris, France.

Objectifs. Apprécier la fréquence des TP au cours du SIDA et en évaluer les caractéristiques cliniques.
Méthodes. Etude macroscopique et histologique du poumon chez 160 patients(pts) décédés de SIDA. Etude des correlations anatomo-cliniques.
Résultats. Une TP a été retrouvée chez 6 pts (3,75 %) et chez une 7ème, actuellement vivante par biopsie pulmonaire (BP) : 5 homosexuels, 1 toxicomane, 1 haïtienne, (âge moyen : 36 ans). La durée de la maladie retrovirale était de 13 mois (4 à 28). Aucun pt n'avait de pneumocystose évolutive. Dans 2 cas un autre agent infectieux opportuniste était isolé dans le poumon, (CMV : 1, CMV + M. tuberculosis : 1). Tous avaient des signes cliniques respiratoires et 4 une hypoxémie sévère ($PaO_2 \leq$ à 60 mmHg à l'air). Les images radiologiques étaient interstitielles (5) ou alvéolaires (2). 2 fois le diagnostic fut obtenu du vivant, par lavage bronchioloalvéolaire (LBA) ou BP. La TP fut responsable du décès 2 fois. L'aspect macroscopique était celui de micro et de macro nodules blanchâtres ou abcédés. Il existait une dissémination de kystes et de trophozoites libres dans des granulomes inflammatoires polymorphes, des foyers nécrotiques et parfois une infestation des macrophages de la paroi alvéolaire. La TP était associée à au moins une autre localisation viscérale extracérébrale. 5 pts avaient aussi une neurotoxoplasmose.
Conclusion. La TP n'est pas exceptionnelle au cours du SIDA. Elle est parfois responsable d'une pneumopathie hypoxémiante. T. gondii mériterait d'être systématiquement recherché dans le LBA ou les BP des pts atteints de SIDA.

W.B.P.24 LONG-TERM SURVIVAL OF AIDS PATIENTS SUCCESSFULLY TREATED FOR TOXOPLASMIC ENCEPHALITIS.

Antoniskis Diana*, Nussbaum JM*, Dannemann BR**, McCutchan JA***, Chiu J****, Leedom JM*, and the California Collaborative Treatment Group. *LA Co.-USC, Los Angeles; **Stanford Univ. Palo Alto; *** UCSD, San Diego; ****UCI-Irvine, California, USA.

Objective-To describe long-term maintenance treatment and survival of AIDS patients (pts) with toxoplasmic encephalitis (TE).
Methods-Follow-up data [greater than 10 weeks (wks)] were available on 18 pts diagnosed at 4 centers since 1987. Pts received 6-8 wks primary therapy (Rx) with either 3 wks IV clindamycin (C) 4.8g/d, then oral C 1.2g/d (8 pts) or sulfadiazine (S) 6-8g/d (10 pts). All pts also received pyrimethamine (pyr) 75 mg/d and folinic acid (FA) 10mg/d. As outpatient maintenance Rx, pts received: oral C (1.2-1.35 g/d)-9 pts, S (2-3g/d)-5 pts, Fansidar once/wk-1 pt, or pyr alone (50mg/d)-1 pt. For pts on C or S, pyr and FA were continued at 50 and 10mg/d. Two pts did not receive maintenance Rx. 11 pts (61%) received concomitant zidovudine (10/11 at 1.2g/d) and 7 (39%) received PCP prophylaxis during maintenance.
Results-16 of 18 (89%) pts are alive at a mean followup of 43.5 wks (range 11-82 wks). 5 pts (28%) experienced relapse of TE; 2 while on S Rx (11%), 1 on pyr alone and 2 on no Rx. All responded to repeat primary anti-TE tx. 3 of 18 (17%) had PCP, 1 each on fansidar, C and no Rx. Reversible neutropenia occurred in 2 pts on zidovudine and pyr, no other serious drug-related complications have been noted.
Conclusions-Long-term survival can be achieved in TE, and is usually determined by response to initial Rx. We recommend use of zidovudine and maintenance anti-TE Rx as incidence of drug-related side effects is low.

W.B.P.25 TOXOPLASMA GONDII PNEUMONIA (TGP) IN AIDS

Eric OKSENHENDLER, J. CADRANEL, A. DATRY, C. SARFATI, C. MARCHE, J.P. CLAUVEL. Hôpital SAINT LOUIS, Hôpital PITIE SALPETRIERE, Hôpital C. BERNARD, Hôpital TENON - PARIS - FRANCE

Between 1984 and 1988, we observed TGP in 11 patients - 10 Europeans and 1 Haitien infected with HIV. 8 had AIDS prior to the diagnosis of TGP, 3 of them had non-Hodgkin lymphoma. Mean CD4 cell count was 30.5 ± 23.4x10^6/l. The clinical features were : fever (11), dyspnea (10) and hemoptysis (2). Chest X-ray showed diffuse bilateral pulmonary infiltrates in all cases. Mean PaO_2 was 46.2 ± 12.8 mmHg. Results of bronchoalveolar fluid, recovered from 10/11 patients and stained by MGG technique showed : a) tachyzoïtes of T. gondii (10/10) associated with P. carinii (n=2), b) increase of neutrophil (7-56%,8/8) and eosinophil (4-14 %, 5/8) counts. In one patient the diagnosis was made at autopsy. Serologic evidence of past infection was observed in 10/10 patients. This ruled out the possibility of primo-invasion. Extrapulmonary involvement was proved in 4 patients : gut (2), brain (2), liver (1), heart (1), spleen (1), and bone marrow (1), and suspected in 3:liver (2), heart (2), spleen (1). 5 patients were neutropenic (<1x10^9/l). Outcome : 4 patients required mechanical ventilation. 9/11 recovered from TGP. 8 received sulfadiazine-pyrimethamine and one trimethoprime-sulfamethoxazole. In conclusion, TGP must be considered in AIDS patients with severe diffuse bilateral pneumonia especially when associated with a very low CD4 cell count and neutropenia.

W.B.P.26 INCIDENCE DE LA TOXOPLASMOSE CEREBRALE AU COURS DU SIDA : DONNEES ANATOMO-CLINIQUES (PARIS 1982-1985).

Saimot, A.G.*; Matthiessen, L.*; Matheron, S.*; Leport, C.*; Marche, C.*; Vedrenne, C.**.
* Hôpital Bichat-Claude Bernard, ** Hôpital St Anne, Paris, France.

Objectifs. 1) Mesurer l'incidence de la toxoplasmose cérébrale (TC)au cours du SIDA. 2) Préciser le pourcentage de cas non diagnostiqués cliniquement. 3) Evaluer l'efficacité du traitement pas sulfadiazine-pyrimethamine (SD). Méthodes. 1) De 11/82 à 4/88, 174 autopsies ont été faites. Les critères anatomo-pathologiques (AP) de TC étaient : présence d'abcès typiques, de kystes et/ou de tachyzoïtes, de micro-calcifications et le marquage par immuno-peroxydase. 2) Les patients ont été traités (T) (au moins 6 semaines de SP) ou non traités (NT). Ils sont guéris (G) ou non guéris(NG) selon les critères AP. Résultats. 1) L'incidence clinique de la TC est 21%. 2) L'incidence autopsique est 35%. 3) Dix huit sur 35 Pts T (51%) étaient NG : 6 (17%) avaient des lésions évolutives (abcès uniques ou multiples et/ou lésions disséminées) et 12 (34%) des abcès en voie de régression. 4) Parmi les patients NT (25 cas) : 10 avaient des lésions encéphalitiques disséminées, 10 des abcès évolutifs, 5 les 2 types de lésions. Conclusions. 1) L'incidence AP minimale de la TC au cours du SIDA est de 35% 2) La différence entre diagnostic AP et clinique (35% vs 21%) est expliquée par l'absence de signes cliniques et/ou scannographiques ou par un traitement trop bref des patients en phase ultime. 3) La grande fréquence de la TC exige des drogues moins toxiques que SD en prophylaxie systématique.

W.B.P.27 CEREBRAL TOXOPLASMOSIS IN DANISH AIDS PATIENTS.

Smith, Elsa*; Pers, C.**; Mathiesen, L.*. * Hvidovre Hosp., Univ. of Copenhagen, DK. ** Rigshospitalet, Univ. of Copenhagen DK.

Objective and methods: To evaluate the diagnostic accuracy of cerebral toxoplasmosis in AIDS patients using clinical features, radiologic characteristics, serology and brain biopsy, we reviewed the charts from 1981-1988.
Results: Five (2%) patients had cerebral toxoplasmosis diagnosed at autopsy but were never treated. Thirtyone (11.4%) of the 273 AIDS patients were treated suspected for cerebral toxoplasmosis up to 6 weeks with daily: pyrimetamin 25 mg + either sulfadiazin 4 g or spiramycin 1-2 g (+ folinic acid). The diagnosis was confirmed in 14 (5.1%) on the basis of regressing focal CAT-lesions consistent with cerebral toxoplasmosis and/or histological demonstration of T.gondii in brain tissue. Eight patient continued on a prophylaxis with sulfadiazin 1 g/day and pyrimetamin 25 mg/week with no relaps. Three of these are alive, 3, 4 and 15 months after the diagnosis and treated with zidovudine as well. Eleven died after 1 to 30 months.
Of the dead: Five never developed pneumocystis carinii pneumonia (PCP), 3 had had PCP prior to T.gondii and 1 of these had taken cotrimoxazol as a PCP-prophylaxis, and 3 developed PCP after the T.gondii infection the 2 taking T.gondii prophylaxis. Two of the living had had PCP 2 and 6 months prior to the diagnosis of T.gondii and got a cotrimoxazole prophylaxis.
Of the 17 patients initially treated suspected for toxoplasmic encephalitis, but who did not get the diagnosis confirmed, 2 are alive doing well 14 and 16 months after treatment. Of the 15 dead 10 got a histopathologic diagnosis: seven PML, 2 malignant lymphomas and 1 aspergillus encephalitis. Five had no biopsy: three later suspected for PML and 2 for a Kaposi's sarcoma.
Conclusion: Toxoplasmic encephalitis occur in Danish AIDS patients with a frequency of 7%. The diagnosis is difficult but should be suspected with focal CAT-lesions and neurological symptoms. Only 45% of the initially treated patients suspected for T.gondii had the diagnosis confirmed and the need for better diagnostical tools and therapies are obvious.

W.B.P.28 TOXOPLASMOSE CEREBRALE ET SIDA EN ESPAGNE.

Ocaña I., De Luis A., Ruiz I., Castro A., Romero J. (*), Martinez-Vázquez J.M..
Departements de Médecine Interne et Neuroradiologie (*). Hospital Valle de Hebrón. Université autonomique de Barcelone. Barcelone. Espagne.

OBJECTIFS: valorer la prévalance, caracteristiques cliniques, evolution et reponse au traitement, ainsi que la rentabilité diagnostique du TAC cerebral en 32 cas de toxoplasmose cerebrale (TC) dans le SIDA.
MATERIEL: nous avons étudié 145 cas de SIDA, 69 d'entre eux (47.5%) presentaient affectation neurologique, parmi eux 32 cas de TC (46.3%).
RESULTATS: La TC a representé la troisième infection opportuniste (IO) en prévalence (22% de tous les cas), apparent après l'infection par Pneumocystis Carinii et la tuberculose extrapulmonaire, étant la plus frequente parmis les 65 malades avec affectation neurologique. Elle a été l'IO qui a permit le diagnostique de SIDA dans le 9.6% de tous les malades de SIDA et le 44.6% des malades neurologiques. 20 malades (62.5%) ont presenté une focalité neurologique (9 avec hemiparesie, 8 avec crise convulsives, 1 avec hemiparestesie et 1 avec affectation des paires craneales); 11 cas (34.3%) ont presenté fièvre, mal de tête et/ou obnubilation; 1 cas a été une trouvaille de la necropsie. Pendant l'évolution, 46,8% des malades ont souffer une focalité neurologique. Le diagnostique a été établi dans tous les cas (sauf dans le cas de la necropsie) par TAC cérébral. En trois cas un premier TAC fut normal mais plus tard apparurent les lesions diagnostiques. La survivance a été comprise entre 2 et 100 semaines, étant actuellements 14 malades vivant. Tous les cas qui ont été traités (30) ont suivi une bonne evolution clinique avec des lesions residuelles dans les TACs posteriours de control. 5 malades ont recidivé après suppresion du traitement; 27 cas ont reçu traitement de forme permanente aucun d'eux ayant mort a cause de la TC.
CONCLUTION: 1- La TC est une IO frequente dans notre pays, se presentant dans le 22% de nos malades de SIDA, representant le 46.3% de l'affectation neurologique. 2- Plus d'une troisième partie des cas ne commencent pas avec une focalité neurologique. 3- Le TAC cerebral a une grande valeur diagnostique (96.3%). 4- Nous proposons faire un TAC a tous les malades VIH positifs avec syndrome fevrile même sans focalité neurologique puisque elle est une exploration peu aggressive et le diagnostique de TC nous permet faire un traitemente efficient et bien toléré par les malades même quand on le fait de manière indéfinie.

W.B.P.29 FAILURE OF HIGH DOSES OF ROXITHROMYCIN (R) IN AIDS PATIENTS WITH CENTRAL NERVOUS SYSTEM TOXOPLASMOSIS (CNST).

Decazes, Jean-Marie*; Doco-Lecompte, T.* and Modai, J.*.
* Department of Infectious Diseases, St Louis Hospital, Paris, France.

Aim. To evaluate R, a new macrolide antibiotic, in CNST of AIDS patients with serious intolerance to conventional therapy. R has good activity in animal models of toxoplasmosis and high concentrations in human brain tissue has been demonstrated.
Methods. R (450 mg Q12h) was administered orally as the single agent, to 8 AIDS patients with CNST in whom serious adverse effects occured after initial pyrimethamine/sulfadiazine (P/S) therapy [cutaneous allergy (n=2), thrombocytopenia ≤25000/µl (n=6)]. Patients were aged 23-74y and their body weights were 51-63kg. All presented with fever, lethargy or confusion, focal neurologic signs, and contrast-enhancing ring-like lesions of the brain. In one patient in whom bacterial brain abcess was initially suspected, CNST was demonstrated by brain biopsy. In others, CNST was demonstrated by a prompt (≤10 days) and clear regression of clinical and CT scan findings after initiation of P/S therapy (0.5/50 mg kg^{-1} Q12h). Duration of initial therapy by P/S was 11-30 days.
Results. Clinical and CT scan findings consistent with CNST reappeared in all patients after 28-45 days of R therapy. In 4 patients in whom P/S therapy could be readministered, regression of clinical and CT scan findings was again obtained, thus confirming relapse of CNST. Despite high dosage, no adverse effect of R was observed.
Conclusion. Despite encouraging experimental and kinetic background, R given at a dosage 3x that recommended for antibacterial chemotherapy was not efficacious in a limited number of AIDS patients with CNST.

W.B.P.30 VESICAL TOXOPLASMOSIS: A NEW SIGN OF PARASITIC DISSEMINATION IN AIDS.

Noël, Grégoire*; Morisset, R.*; Grégoire, M.*; Lemarre, L.* and Lepointe, S.*.
*Université de Montréal and Hôtel-Dieu de Montréal, Montréal, Québec, Canada.

Protozoan affection remains the first killer of patients afflicted with AIDS. As of January 1989, 25 cases of Toxoplasmosis (T) were observed in such patients hospitalized in our institution.
Objective: To report a peculiar manifestation of T. among AIDS sufferers.
Methods: Since the first evidence of HIV seroconversion in December 1982, at risk patients were followed closely for prompt diagnosis and treatment. Charts were thoroughly studied and classified according to demographic items. Toxoplasmosis was documented by at least 2 of the following tests: serology, CT scanning, nuclear imaging, histology.
Results: Sixteen white males (12 homo, 2 hetero, 2 bi.) and 9 Carribeans heterosexual (5 W, 4 M) were recorded. Ages varied from 23 to 58 years old (mean 38.2, median 37). Sixteen patients died between 8 days and 42 months following the diagnosis (mean 9.4, median 6.5 months) while 2 cases were diagnosed at autopsy. One patient showed pulmonary envolvement and 24 displayed central nervous system infection. Of these, a 23 y. o. girl had also vesical T. 16 months following the diagnosis of AIDS based on cryptosporidiosis, P.C.P. and generalized V-Z viral infection. She had an intractable bladder infection unresponsive to adequate antibacterial drug.
Conclusions: We point out the first reported case of vesical T. in AIDS. Such diagnosis must be suspected whenever urinary complaints cannot be ascribed to evident microbiological infection.

W.B.P.31 THERAPEUTIC OF TOXOPLASMIC ENCEPHALITIS IN AIDS PATIENTS

Mendonça, João S.; Lobo, I.M.F.; Stefani, H.N.; Biancalana, M.L.N.; Rodrigues, G.A. and Levi, G.C.

Serviço de Moléstias Infecciosas, Hospital do Servidor Públicu Estadual, São Paulo, Brazil.

Seventeen patients with AIDS and toxoplasmic encephalitis were studied regarding therapeutic response and adverse effects, diagnosis being established on clinical and tomographic basis. All patients had positive specific serological tests; IgM was always negative and IgG was always > 1/256; median CD4+ count was 222 cells/mm3. Pyrimethamine, sulfadiazine, and clindamycin were used in various combinations or, in few cases, due to allergic or toxic reactions to the other drugs, as monotherapy. The same drugs and Fansidar were used as suppressive therapy. Thirteen patients improved; and four died (three of them before completing 10 days of treatment). Relapse was observed in 50% of the cases, and the mean survival time was 161 days.
Overall there are eight necroscopic studies for clinical pathological correlation.
The authors call the attention to the favourable therapeutic response even when monotherapy with clindamycin was used, and the high incidence of side effects of therapeutics and relapse of the disease in spite of suppressive therapy.

W.B.P.32 IN VITRO SECRETION OF TOXOPLASMA SPECIFIC ANTIBODIES BY PERIPHERAL BLOOD CELLS FROM HIV1 INFECTED SUBJECTS.

Vendrell, J.P.**; Ducos, J.**; Reynes, Jacques***; Huguet, M.F.*; Cannat, A.*; Serre, A.**.
* INSERM U65, ** Laboratoire d'Immunologie, Hôpital Lapeyronie, *** Service Maladies infectieuses, Hôpital St Eloi, MONTPELLIER, FRANCE.

INTRODUCTION. Severe cerebral complications of Toxoplasmosis occur in 10 to 20 % of AIDS patients. Serology is no great help for their diagnosis which relies on clinical and scanner arguments. We wondered whether specific B cells could not be present in the blood stream at earlier stages of active toxoplasmosis infection together with the HIV1 secreting cells.
METHODS. PBMC culture supernatants from 43 HIV1 seropositive and 24 seronegative subjects were incubated in wells of Behring or Pasteur Toxoplasmosis antibody kits. An amplifying enzymatic complex was used to reveal the in vitro secreted and fixed antibodies.
RESULTS. a) In vitro production of Toxoplasma antibodies was detected in 19 of the 36 "HIV1 and Toxo seropositive" and in none of the HIV1 "seropositive" but "Toxo seronegative" subjects, b) Although 20 of the 24 HIV1 "seronegative" subjects were "Toxo seropositive" none of them gave positive results in the in vitro Toxo test, c) Scanner and clinical evidence of cerebral toxoplasmosis was found in only 3 of the 19 "HIV1 and Toxo positive" subjects and isolated neurologycal symptoms in only 7 others, d) A specific and selective inhibition of the Toxo in vitro test (and not of the HIV1 test) was observed after preincubation on the PBMC with Toxoplasma antigens (Kindly provided by Pr Capron, Lille).
CONCLUSION. Toxoplasma antibody secreting cells are present in the blood stream of some but not all HIV1 infected subjects. Their detection could provide a tool for the diagnosis and the early treatment of active Toxoplasmosis.

W.B.P.33 THE VALUE OF PYRIMETHAMIN/SULFADOXIN (FANSIDAR) IN THE PREVENTION OF CNS-TOXOPLASMOSIS IN AIDS- PATIENTS

Salzer, Thomas*, Rolfs, A.**, Höffken, G.*, Doppermann, K.H.*, Hamm, B.*** and Riecken, E.O.*.

*Med.Clin., **Neurological and ***Radiological Department of Klinikum Steglitz, Freie Universität Berlin, FEDERAL REPUBLIC OF GERMANY

Objective. Is FANSIDAR (FAN) 2 tbls/week sufficient for prevention of CNS-toxoplasmosis (C-Tox) in AIDS-patients (pts)?
Methods. Retrospective analysis of 16 pts. treated for C-Tox between 1986 and 1988.
Results. Sixteen human-immunodeficiency-virus-seropositive pts with acute C-Tox (typical intracerebral lesions in NMR a/o CT scan) were treated with pyrimethamin (PY), mean dos. 50mg/d, in combination with either sulfadiazin (SU, 4,0g/d) or clindamycin (CL, 1,8-2,4g/d) in case of SU-side effects. 4 of these 16 pts. developed their C-Tox despite secondary long term prevention of P.carinii pneumonia with FAN (50mg/1,0g/week). 14/16 pts. (87,5%) showed complete (10/16) or partial (4/16) response (residual scan lesions or neurological defects), 2 pts. died. Treatment was continued as long term therapy with FAN (50mg/1,0g/week) in 4 pts., PY alone 50 mg/d in 6 pts., or PY + CL (1,8-2,4g/d). None of the 10 pts with complete remission developed a relapse, 3/4 pts. with partial remission relapsed, two of them despite secondary long term therapy with FAN and one pt. with PY/CL. Thus, 6/16 pts. (37,5%) developed C-Tox relapses or acquired acute C-Tox while under long term therapy with Fansidar.

Conclusions: These retrospective data indicate that (1) Fansidar in a dosage of 50mg PY / 1,0g SU per week might be of limited value for the primary or secondary prevention of C-Tox in AIDS-pts. and (2) that partial remission of C-Tox seemed to be a major risk factor for C-Tox relapse.

W.B.P.34 TREATMENT OF CNS TOXOPLASMOSIS IN AIDS PATIENTS. RESULTS OF PROSPECTIVE STUDIES USING PYRIMETHAMINE AND MACROLIDE ANTIBIOTICS.

Ruf, Bernhard *, Pohle, H.D.* and Iglesias, J.R.**
* Departments of Internal Medicine and ** Neuropathology, Rudolf Virchow University Hospital (Wedding), Freie Universität Berlin, FRG

For treatment of cerebral toxoplasmosis pyrimethamine in combination with sulfonomides is commonly used. In our study the sulfonamide component was replaced by macrolide antibiotics. The results of treatment with pyrimethamine and with one or two macrolides were compared: with clindamycin and spiramycin (three drug regimen) and with clindamycin (two drug regimen). For maintenance therapy the effectiveness of pyrimethamine/sulfadoxine was studied.

Dosages: 1.5 mg pyrimethamine/kg body weight/d, 2.4 g clindamycin/d and 9 Mill. IU spiramycin/d for 3 weeks. Prophylaxis after acute therapy: 50 mg pyrimethamine and 1000 mg sulfadoxine (= 2 tablets Fansidar®) once a week.

Three drug regimen: therapy was effective in 25/26 cases. Relapse occured in 1/19 cases under maintenance treatment but in all six patients who had omitted the prophylaxis. Two drug regimen: therapy was effective in 12/13 cases. Two of 13 patients developed a relapse under prophylaxis. Hematologic side effects were equal for both regimens, but could be controlled by folinic acid given from the start of therapy in most cases. Skin rashes were observed in 10 cases.

Therapy regimen with pyrimethamine and macrolide antibiotics and maintenance treatment were proven to be effective. Relapses are mainly due to discontinuation the prophylaxis.

W.B.P.35 LOCALISATIONS DE LA TOXOPLASMOSE DANS LE TUBE DIGESTIF (T.D.) AU COURS DU SIDA. ETUDE ANATOMO-CLINIQUE.

Marche, C.; Mayorga Ruben.; Clair, B.; Trophilme, D.; Frottier, J.; Saimot, A.G.;
Hôpital Bichat-Claude Bernard, Paris, France.

Objectif. Evaluer la fréquence de la toxoplasmose digestive et préciser ses aspects anatomo-cliniques.
Méthodes. Etude macroscopique et histologique systématique du T.D. de 160 patients (Pts) décédés de SIDA, corrélée avec les données cliniques.
Résultats. Le T.D. est atteint 7 fois (5 homosexuels européens, 1 zaïroise, 1 haïtienne; âge moyen : 37 ans ; durée moyenne de la maladie : 10 mois). Sont intéressés 2 fois tout le tube digestif, 1 fois le grêle et le colon, 4 fois seulement l'oesophage (n = 1), le grêle (n = 1) ou le colon (n = 2). L'aspect macroscopique est banal (érosions, pétéchies) sauf dans 2 cas : aspects de tumeur gastrique diffuse (1 cas) et de recto-colite hémorragique (1 cas). Toxoplasma gondii (T.G.) peut infester tous les types cellulaires ; kystes et trophozoïtes libres sont mis en évidence sur toute l'épaisseur de la paroi, dans des lésions inflammatoires et/ou nécrotiques, nodulaires ou diffuses. Dans 5 cas T.G. est le seul agent pathogène ; 2 fois il est associé à des cryptosporidies (n = 1) et à une infection par Cytomégalovirus et Mycobacterium Avium Intracellulare (n = 1) ; 6 des Pts ont une neurotoxoplasmose et tous au moins une autre localisation viscérale. La clinique se résume à une diarrhée profuse (6 fois) et/ou à des douleurs abdominales (3 fois).
Conclusion. La toxoplasmose digestive existe ; T.G. devrait être recherché systématiquement sur les biopsies digestives, au besoin par immunoperoxydase.

Infections liées au SIDA : diarrhée
AIDS Related Infection: Diarrhea

W.B.P.36 ADENOVIRUS ISOLE DU TUBE DIGESTIF CHEZ 20 PATIENTS SIDA, QUELLE SIGNIFICATION CLINIQUE ?

Salmon, Dominique, Leport J., Garcia J., Leport C., Bricout F., Vilde J.L. Hôpital Claude-Bernard. Paris. France.

Objectif. Préciser le rôle des adénovirus au cours du SIDA.
Méthodes. Etude rétrospective des dossiers de 20 patients (pts) SIDA chez lesquels un adénovirus a été isolé des selles ou des biopsies coliques entre août 1987 et septembre 1988.
Résultats. Tous avaient des signes digestifs : diarrhée (n=18), douleurs abdominales (n=3).Trois pts avaient une ulcération anale. La coloscopie, était normale chez 8/18 pts, et montrait une colite inflammatoire ou ulcéreuse chez 10/18 (55 %) avec histologiquement des inclusions compatibles avec une infection à CMV (n=4), des cryptosporidies (n=1),et aucun autre agent pathogène que l'adénovirus (n=3). Un adénovirus était isolé des selles (n=11), des biopsies rectales (n=12) et/ou caecales (n=8) ou de l'ulcération anale (n=2). Les sérotypes des 4 souches étudiées étaient 15, 17, 22 et 24. Les recherches d'adénovirus étaient réalisées à la fois dans selles et biopsies chez 10 pts : elles étaient positives aux deux niveaux chez 6 pts (grp.1 et positives seulement dans les selles chez 4 pts (grp.2). 4 sur 6 pts grp.1 et 4 sur 4 pts grp.2 avaient une colite endoscopique. Une virémie CMV était présente chez 12 sur 19 pts (63 %), et 8 sur 20 pts (40 %) avec une localisation viscérale à CMV.
Conclusion. Ces résultats (1) suggèrent la possible responsabilité des adénovirus dans certaines manifestations digestives au cours du SIDA, (2) soulèvent la question des relations entre CMV et adénovirus au niveau du tube digestif chez ces pts.

W.B.P.37 BLASTOCYSTIS HOMINIS INFECTION IN AIDS PATIENTS.

K. Rolston, S. Rodriguez. The University of Texas M. D. Anderson Cancer Center, Houston, Texas, U.S.A.

Although associated with some instances of human gastrointestinal disease, the pathogenicity of Blastocystis hominis is still under question.
Objective - To evaluate the pathogenic potential of B. hominis in AIDS patients.
Methods - The records of HIV-infected individuals whose stool specimens contained B. hominis (>5 per 400x field) were reviewed.
Results - Seven such patients were seen at our institution. All had significant diarrhea (>4 bowel movements per day) nausea, abdominal cramping, fever and weight loss. Stool specimens of 3 patients contained only B. hominis. The remaining 4 had other potential intestinal pathogens (Entameba histolytica, Giardia lamblia) which have been implicated as co-pathogens with B. hominis. All seven patients responded to therapy (metronidazole or trimethoprim/sulfamethoxazole) with resolution of symptoms and erradiation of organisms from stool. No relapses occurred (follow-up - 4 months). No other causes for their diarrhea were found.
Conclusions - B. hominis should be considered a potential pathogen in AIDS patients and may co-exist with other intestinal pathogens. Specific therapy usually results in resolution of the infection. Relapses are rare. In patients who do not respond, other causes of diarrhea should be investigated.

W.B.P.38 VARIABLE LOCALIZATION OF INTESTINAL CRYPTOSPORIDIOSIS IN AIDS.

Heller, Todd D; Tierney, AR; Kotler, DP.
St Luke's-Roosevelt Hospital Center, Columbia University, New York, NY, USA.

Objective. To examine the localization of cryptosporidial (Crypto) infection in the gastrointestinal tracts of patients with AIDS.
Methods. In a retrospective review of biopsies from 25 AIDS patients with Crypto, the small intestine was the primary site of involvement in 16 patients, the colon was the primary site of involvement in 9 patients, and no patient had severe disease in both sites. The influence of disease localization was studied prospectively in 8 patients with jejunal Crypto and in 5 patients with colonic Crypto. Studies of oocyst excretion, small intestinal structure, and the absorption of sugar (xylose) and fat (triolein) were performed.
Results. Diarrhea was more severe in patients with jejunal Crypto and was associated with greater cyst excretion, more jejunal injury and more xylose malabsorption. Fat malabsorption was abnormal in both groups.

Disease site	Jejunum	Colon	p
Oocyst excretion (#/HPF)	17.8±6.7	2.4±1.9	NS
Jejunal villus ht (#cells)	50.0±3.2	84.8±8.3	p<0.005
D-xylose (1 hr serum)(mg/dl)	12.5±2.4	42.4±5.5	p<0.001
Triolein breath(%dose, 5th hr)	0.48±0.21	0.78±0.28	NS

Conclusions. Crypto has a variable localization the intestine. Intestinal structural and functional abnormalities correlate strongly with the localization of Crypto.

W.B.P.39 COLONOSCOPIC ETIOLOGICAL DIAGNOSIS OF DIARRHEA IN AIDS

Bonfim de Lima, Dirce; Jurado,E.; Favoreto,C.; Treistman,M.; Passos,R.
Universidade do Estado do Rio de Janeiro,Rio de Janeiro,Brasil.

From August 1985 to September 1988, 18 patients were studied by the same phisicians at the Department of Infectious Diseases and private clinic. They presented diarrhoea for more than 30 days. Among them were 14 homosexual men, 2 blood receivers and 2 women married with bisexual men. After negative laboratorial investigation for common intestinal parasites in AIDS, colonoscopies with biopsies from caecum through rectum (fibrocolonoscope ACMI and video-colonoscope Welch Allyn) were performed in 16 patients. The examination showed: normal mucosa (4 cases), swollen and eritematous mucosa without friability (6 cases) and sick mucosa with multiple ulcerations (6 cases). The histopathology showed Cytomegalovirus colitis (9 cases), cryptosporidiosis (1 case) and nonspecific inflamatory disease at the remaining ones.

There were two patients not submitted to colonoscopy which presented Cytomegalovirus colitis. One of them had peritonitis due to a left colon ulcer perforation found at surgery and the other at post mortem examination. The diagnosis were made by histopathology of the surgical specimen and autopsy respectively.

After given anti-viral therapy, two patients with Cytomegalovirus colitis remained with diarrhoea. One of them had cryptosporidiosis and the other Shigella flexneri in the stool culture.

W.B.P.40 INCIDENCE OF INFECTIOUS GASTROENTERITIS IN SPANISH AIDS PATIENTS

Josep Mallolas; Moreno A, Miro JM, Gatell JM, Latorre X, Soriano E. Infectious Diseases Unit. Hospital Clinic. University of Barcelona. Barcelona, Spain.

OBJECTIVE. To describe the characteristics of the infectious gastroenteritis (IG) in 226 Spanish AIDS cases.
METHODS. Since 1984, all patients who fulfilled the CDC criteria for AIDS case definition were prospectively followed. Seventy four (33%) were male homosexuals (HMS) and 132 (60%) drug addicts (DA).
RESULTS. Fifty nine episodes of IG (defined as the isolation of one (44 episodes) or more (15 episodes) microrganisms in the feces or in the intestinal mucosa) were identified in 46 of the 226 AIDS cases (20.3%). All but 2 were males and the mean age was 36 (range 24-59); twenty seven were HMS (58%) and 17 (36%) DA (p< 0.001). The IG alone or associated with other opportunistic infection was present at the moment of performing the diagnosis of AIDS in 30 of the 46 cases cases (65%). The microrganisms were: Cryptosporidium (19), G. lamblia (12), Entamoeba coli (8), I. belli (7), Cytomegalovirus (7) (postmortem diagnosis 6), Salmonella sp. (7) (five with concomitant bacteremia), C. jejuni (4), T. trichura (2), E. nana (2), and MAI, Y. enterocolitica and S. stercoralis in one case each. All episodes of IG, but 4 caused by cryptosporidium, were self-limited or responded to treatment. The IG was the main or an associated cause of death in 5 of the 25 patients who have already died.
Conclusion. IG is very common among Spanish AIDS patients (mainly among HMS) and often are the first manifestation of AIDS. The most frequent microorganism was Cryptosporidium.

W.B.P.41 GASTROINTESTINAL MULTIINFECTION IN AIDS PATIENT: A CASE REPORT

Kronfeld, Matias*; Sprinz, E**.
*Universidade Federal do Rio Grande do Sul, Porto Alegre, Brasil
**Hospital de Clinicas de Porto Alegre(HCPA), Rio Grande do Sul, Brasil

Objective. Report a gastrointestinal multiinfection in AIDS patient in Rio Grande do Sul(RS) state.
Case Report. A 29 years old, white, drug addict and promiscuous was hospitalized with a copious, explosive, bloody diarrhea. First stool analysis revealed Strongyloides stercoralis and Ascaris lumbricoides. Thiabendazol and mebendazol were started without great improvement. Her stool culture yelded Shigella flexnerii and cotrimoxazol was initiated with improvement of the diarrhea. Another stool analysis showed Candida sp. and Cryptosporidium sp. Amphotericin B was added and a great improvement has been noticed. She was discharged after 20 days with 2 diarrheal episodes per day. Her stool analysis was negative, except for the presence of Cryptosporidium sp.
Conclusion. When treating AIDS patients, is important to know that infections are rarely single, and this report is a perfect example of the transformations going on gastrointestinal system of these patients.

W.B.P.42 ROTAVIRUS AS A DIARRHEAL AGENT IN ADULT AIDS PATIENTS.

Siim, Jihad*, DeLuca, P., Perez, G., Shah, J., DeLuca, A. Saint Michael's Medical Center, Newark, New Jersey, U.S.A.

Objective: To determine incidence and importance of rotavirus as a cause of diarrhea in AIDS patients.
Methods: Stool samples were assayed by latex agglutination and Elisa technique for the presence of rotavirus. These stool samples were collected from 12/88 through 1/89 when the incidence of rotavirus was at its height in the corresponding pediatric population. The medical charts of these patients were reviewed for symptoms.
Results: Eighteen patients had stool samples sent for study. Eight of these patients had symptoms of diarrhea and one of these had rotavirus detected by Elisa. Mycobacterium Avium-Intracellulare was the most common cause of diarrhea among the virus detected in their stools.
Conclusion: Rotavirus was not found to be a significant cause of diarrhea in adult AIDS patients. Detection of this agent also may not explain the diarrheal syndrome even when found.

W.B.P.43

EFFICACITE DE LA SOMATOSTATINE LONGUE ACTION (SMS 201 995)& DANS LE TRAITEMENT DES DIARRHEES ET DANS LES CYTOPENIES DE DEUX MALADES ATTEINTS DE SIDA.

Routy JP* Latreille J* Phaneuf D** Neemeh JA* Monte M* Beaulieu R*.
Hématooncologie* et maladies infectieuses** Hötel Dieu Montréal H2W1T8 Canada

La somatostatine longue action a montré une efficacité dans la diarrhée du SIDA purement symptomatique chez 2 patients. Nous avons observés ces mêmes résultats mais associés à une correction de la cytopénie chez 2 SIDA.
Obs.1 : un homosexuel de 32 ans avec sarcome de Kaposi et pneumocystose présentait une diarrhée invalidante avec une cachexie et une perte de 6 kilos en 2 semaines. Aprés l'échec de tous les traitements symptomatiques et antibiotiques larges un traitement par SMS à la dose de 100 mcg par s/c q8 heures a arrêté la diarrhée. Au 15ème jour nous avons stoppé la SMS avec une récidive de la diarrhée. La coproculture des selles a été positive à Micobactérium Avium uniquement. Un traitement par Rifampicine et Amikacine n'a pas stérilisé les selles. Les globules blancs avant et aprés traitement (15°Jour) passèrent de 660mm3 à 5600, les CD4 de 5/mm3 à 54, les plaquettes de 67000 à 228000/ml, l'hémoglobine resta stable. Le patient a grossi de 8 kilos en trois semaines.
Obs.2 : une hétérosexuelle de 28 ans présentait une pneumocystose avec cachexie, 12 selles liquides/jour. L'examen des selles (bactéries, parasites, champignons) fut négatif. Aprés traitement de 100 mcg 3 fois/jour, arrêt de sa diarrhée. Dés la cessation du traitement, récidive de la diarrhée et contrôle à la reprise du SMS. Les globules blancs avant et aprés traitement (15è jour) passèrent de 800 à 1100/mm3, les plaquettes de 40000 à 110000. La SMS semble être un traitement symptomatique de la diarrhée du SIDA et a permis la correction de la cytopénie. Une étude est nécessaire pour en comprendre les mécanismes.

& SMS 201 995 Laboratoire SANDOZ

W.B.P.44

GASTRIC LEISHMANIASIS IN AN AIDS-PATIENT.

Pesce,Alain; Vinti,H.; Taillan,B.; Saint-Paul,M.C.; Marty,P.; Le Fichoux,Y.; Cassuto,J.P.
C.H.R.U. Nice, France.

Visceral leishmaniasis has been previously described in HIV seropositive patients and even proposed as a new opportunistic disease.
A 28-old patient, seropositive for HIV, followed since 1985, was admitted for weight loss, epigastric pain. Two years ago, he had developped cerebral toxoplasmosis. Since June 1987, he received zidovudine therapy, which was stopped in August 1988 for hematological toxicity. On admission, blood cells count was : 1,4. 10.9/l leucocytes, 3,58. 10.12/l erythrocytes, 34. 10.9/l platelets, hemoglobin level was 116 g/l. Immunoglobulins were normal at ponderal dosage. CD4 positive blood cells were < 10/mm3. Endoscopic examination showed an ulcer on cardia. Anatomopathologic examination revealed a gastric localisation of leishmania. Medullar examination and specific culture were positive. Specific serology was negative. There was not any parasite on skin and blood examination. Clinical status was dramatically improved by specific therapy of ulcer and sodium stibiogluconate (Pentostam*) (600 mg/day during 3 weeks). At the end of the first cure, we noted : 5,5. 10.9/l leucocytes, 77. 10.9/l platelets and hemoglobin level was 120 g/l. Severe lymphopenia was persistent. Zidovudine therapy was started again. At our knowledge, gastric localization of leishmaniasis revealing visceral disease had not been previously described, since intestinal involvment is well known. It would be a positive outline for the "opportunistic" character of leishmaniasis in AIDS-patients. Research of visceral leishmaniasis seems to be necessary in endemic area, in HIV seropositive patients with lymphopenia, mainly with hematological abnormalities.

W.B.P.45

SUCCESSFUL USE OF HYPERIMMUNE BOVINE COLOSTRUM TO TREAT *CRYPTOSPORIDIUM* INFECTION IN AN AIDS PATIENT

Ungar, Beth*; Ward, D.; Fayer, R.** and Quinn, C.*.
*Uniformed Services University of the Health Sciences, Bethesda, MD, USA,
**United States Department of Agriculture, Beltsville, MD, USA

Cryptosporidium is a protozoan parasite of the human gastrointestinal tract which can cause life-threatening diarrhea in immunodeficient patients. Although close to eighty agents have been tried with occasional anecdotal success, treatment remains primarily limited to hydration. We describe a 38-year-old homosexual male with antibody to human immunodeficiency virus and *Cryptosporidium*-related diarrhea. The patient excreted 6 to 12 liters of stool per day for at least three months, two in hospital. Repeat stool examinations identified no bacterial or parasitic pathogen other than *Cryptosporidium*. Trials with more than six anti-diarrheal medications, including spiramycin, were ineffective and the patient finally received bovine colostrum hyperimmune to *Cryptosporidium* by direct duodenal infusion. The colostrum was produced by parenteral injection and intramammary infusion of oocysts into pregnant dairy cows; resulting colostrum had >1:200,000 titers of specific bovine anti-*Cryptosporidium* IgG-1, IgA and IgM. During infusion, the patient's fecal output decreased to less than 2 liters per day and 48 hours after treatment, stools were fully formed and oocysts to *Cryptosporidium* could not be found. The patient remains asymptomatic 3 months later. Hyperimmune bovine colostrum offers an exciting possible new treatment for cryptosporidiosis; the active factor(s) and mechanisms of action should be characterized.

W.B.P.46

A COMPARISON OF ELECTRON MICROSCOPY (E/M) AND LIGHT MICROSCOPY (L/M) IN THE DIAGNOSIS OF CRYPTOSPORIDIAL AND BLASTOCYSTIS INFECTION

Connolly, G.M.; Tovey, G.; Gazzard, B.G., St. Stephen's Hospital, London. UNITED KINGDOM

Objective To assess the value of L/M and E/M in the identification of apparent cryptosporidial infection.
Methods Rectal biopsy and stool specimens were examined by L/M and E/M from 40 AIDS patients with diarrhoea (at least 3 liquid motions/day for longer than one month).
Results E/M confirmed the presence of cryptosporidium in 4 of 11 patients identified by L/M and in no patients where this organism had not been seen. The 4 patients had typical cryptosporidial infection with mean weight loss of 9 Kgs. and large volume diarrhoea (mean 1.9L/day). They all died 3, 7, 9 and 24 months after diagnosis. In the other 7 patients, an alternative diagnosis was suggested at E/M (blastocystis 6 and dead cysts of giardia in 1). Four of the 6 patients with blastocystis are still alive 9, 12, 12, and 21 months after diagnosis. They had lost little weight at presentation (mean 4 Kgs.) and had low stool volumes (mean 0.7L/day). A subsequent AIDS diagnosis has been made in 3 of these patients.
Conclusion Light microscopy may confuse blastocystis and cryptosporidal infection. The former has a better prognosis, is not a feature of AIDS and presents with fewer clinical symptoms.

W.B.P.47

TREATMENT OF CRYPTOSPORIDIAL INFECTION WITH RECOMBINANT INTERLEUKIN-2 (rIL-2)

Connolly, G.M.; Owen S.L.; Hawkins, D.A.; Gazzard, B.G.
St. Stephen's Hospital, London, England. UNITED KINGDOM

Objective To assess the response of cryptosporidial diarrhoea to rIL-2.
Methods Three patients with cryptosporidial diarrhoea (present in 3 stool specimens and rectal biopsy) had stool volumes measured for four days prior and seven days after a course of intravenous rIL-2 (400ug over 2 hours daily for 14 days). A patient with severe right upper quadrant pain, sclerosing cholangitis, cytomegalovirus (CMV) colitis and cryptosporidium on rectal biopsy was treated similarly.
Results Ina ll four patient cryptosporidium was not found in stools or rectal biopsy after treatment. In two or three patients with diarrhoea the average daily stool volumes fell from 1.6 and 1.5 litres per day to 0.75 and 0.3 litres per day. Remission was maintained for two weeks in one patient who died of pneumonia and for two months in another patient who died of CMV colitis. The third patient had visceral Kaposi's sarcoma and no reduction in stool volumes and died within two months. After starting a course of rIL-2 in one patient with cholangitis his abdominal pain was markedly reduced but treatment was discontinued after seven days because of marked hypotension, pyrexia and hemiparesis from which he recovered. He subsequently received Foscarnet for CMV colitis and remains well four months later. Three of the four were febrile in response to rIL-2 and the alkaline phosphatase was significantly raised in two during treatment.
Conclusion rIL-2 is an effective treatment for cryptosporidial diarrhoea but may cause severe reactions.

W.B.P.48

GASTROINTESTINAL CRYPTOSPORIDIOSIS IN RIO GRANDE DO SUL(RS) STATE: THE HIGHEST INCIDENCE

Sprinz, Eduardo**; Kronfeld, M*; Capobianco, K*, Barth, A*, Petrillo, V*
+Universidade Federal do Rio Grande do Sul, Porto Alegre,Brasil
++Hospital de Clínicas de Porto Alegre(HCPA), RS, Brasil

Objective. Establish the incidence of gastrointestinal cryptosporidiosis in AIDS patients in RS.
Methods. It was reviewed, at random, 50 registers of AIDS inpatients at HCPA between july and november 1988. 8 cases were excluded because they did not meet the inclusion criteria(at least 4 stool analysis for cryptosporidium sp. in an acid-fast smear).
Results. 52,4%(N=22) were positive, and 47,6%(N=20) were negative for cryptosporidium sp.
Conclusion. Gastrointestinal cryptosporidiosis in RS is one of the highest incidence in the world. Therefore, it is important to consider this disease when dealing with an AIDS patient coming from RS.

Infections liées au SIDA : syphilis
AIDS Related Infection: Syphilis

W.B.P.49 ATYPICAL SECONDARY SYPHILIS IN HIV SEROPOSITIVE PATIENTS

Caumes E.*, Janier Michel**, Janssen F*, Rybojad M.*, Dallot A.* and Morel P.**
* Department of Dermatology and ** STD Clinic, Hôpital Saint-Louis, Paris, France.

Objective : to describe secondary syphilis in 8 HIV-seropositive patients.
Methods : retrospective study of clinical, serological, bacteriological and histopathological data in 8 consecutive patients (HIV +) seen in our department from 1984 to 1988 for a secondary syphilis.
Results : Patients : 8 males (mean age : 36,8 ± 10,2 years old), 7 homosexual, 1 drug addict, 2 with AIDS, 2 with the lymphadenopathy associated syndrome and 4 with asymptomatic HIV infection. 3 of them had a previous treated syphilis and only one had a history of chancre before the eruption. Clinical presentation was atypical in five : one livedo vasculitis of the trunk, two palmo-plantar keratodermas, two malignant ulcerative syphilis. The 3 others had a classical presentation (roseola or papular syphilids). Diagnosis was made on serology (high titers of antibody) in 8, darkfield examination in 1, histopathology (numerous plasma cells) in 6.
All were cured with classical recommended Penicillin therapy for early syphilis.
Conclusion : Clinical presentation of secondary syphilis during HIV infection was atypical in 5/8. In such patients, syphilis is more than ever "the great imitator". On the other hand, the serological and histological data were typical of secondary syphilis and led to an easy diagnosis.

W.B.P.50 NEUROSYPHILIS IN HIV-INFECTED PATIENTS: EVIDENCE OF UNRELIABLE SEROLOGIC RESPONSES

Rolf Malessa*, M. Bahro*, N. Brockmeyer**, R.Biniek***, G. Schwendemann*
Dept. of *Neurology, **Dermatology, University Clinic Essen, ***Dept. of Neurology, University Clinic Aachen, FRG.

Objective and Methods.The combined infection with Treponema pallidum and HIV by unknown interaction leads to an atypical presentation of Neurosyphilis (NS), but reagin and treponemal antibody tests have remained the cornerstone of diagnosis.
We report on 4 HIV-infected men (CDC group II and III) with NS (one meningovascular, two meningeal type(s), one papillitis) who failed to develop typical serologic responses. High dose antibiotic therapy was effective in all cases. Serum and CSF were examined for FTA, IgM-FTA, TPHA and cardiolipin reaction. The TPHA-serum/CSF-quotient was calculated. In 3 patients the relative concentrations of HIV-antibodies in serum and CSF were determined by serial dilutions in an anti-HIV ELISA (Abbott, Dupont). CSF was examined for cell count, protein content, oligoclonal bands and intrathecal IgG production.
Results. There was serologic evidence for a previous syphilitic infection in all patients, but the serologic indicators of active NS, the cardiolipin reaction and the IgM-FTA in CSF, were negative. In addition, three of the patients showed no serologic signs of active syphilis in serum. One patient developed a relaps of NS despite an adequately high dose antibiotic therapy.

W.B.P.51 SYPHILITIC MYELOPATHY WITH HUMAN IMMUNODEFICIENCY VIRUS: A TREATABLE CAUSE OF SPINAL CORD DISEASE

Joseph R. Berger, M.D.*, G.Hensley, M.D.**, L.Moskowitz, M.D.#.
From the Departments of Neurology*, Internal Medicine*, and Pathology**, the University of Miami School of Medicine, and the Department of Pathology#, Baptist Hospital, Miami, Florida, U.S.A.

Three individuals with syphilic myelopathy occurring in association with human immunodeficiency virus (HIV) infection are described. One patient responded dramatically to high dose intravenous penicillin therapy. In the other two patients, syphilitic spinal cord involvement was confirmed at autopsy by the presence of lymphocytic fibrotic leptomeningitis, chronic periphlebitis, and microglial infiltrates of the spinal cord. Both also exhibited radiculitis. One patient had clinical features of cervical radiculopathy, paraparesis, and double incontinence. The other was treated for neurosyphilis three months before death when she presented with an altered mental state, acute left hemiparesis, and hemihypalgesia with positive syphilis serology.

Syphilis needs to be considered in the differential diagnosis of any patient developing a myelopathy in association with HIV infection. Because of the diverse nature in which syphilis may affect the spinal cord, any HIV-seropositive patient with a progressive, unexplained myelopathy and a positive serum FTA-abs should be considered for therapy with intravenous aqueous penicillin, 12 to 24 million units daily, for a minimum of 10 days, even in the absence of a positive cerebrospinal fluid VDRL.

Supported in part by National Institute of Neurological Diseases and Strokes Program Project P01-NS25569.

W.B.P.52 HISTORY OF AND CONVENTIONAL TESTS FOR SYPHILIS IN HIV-1 SEROPOSITIVE HOMOSEXUAL MEN IN THE BALTIMORE MACS

Alwood Karla, Fox R, Hook E, McArthur JH, Starkey D, Saah A. The Johns Hopkins Medical Institutions, Baltimore, MD, USA

Objective To determine the validity of syphilis testing in HIV-1 seropositive homosexual men with self-reported syphilis history.
Methods Sixty HIV-1 seropositive Rapid Plasma Reagin (RPR)- men in the Baltimore MACS were stratified by self-reported history of syphilis and tested for evidence of past or present infection using the Fluorescent Antibody Absorbed (FTA) assay. 39/60 men had lumbar punctures performed using Venereal Disease Research Laboratory (VDRL) analysis of cerebrospinal fluid (CSF).
Results Fifteen men reported history of syphilis, all before 1984. FTA tests were reactive in 13/15 (Sensitivity = 86%). CSF-VDRL analysis was available in 8/13 of these men and were all nonreactive. In 45 men with no history of syphilis, the FTA was reactive in 2 (Specificity = 43/45 = 96%). CSF-VDRL evaluation was negative in 31 of those tested including one participant with +FTA and negative history.
Conclusion Both sensitivity and specificity of reported lifetime history of syphilis are high compared to FTA testing in this small highly screened HIV-1 seropositive population. The 4% (2/45) of FTA+ men without reported history may be the result of recall error, false positive treponemal tests, or inadvertent treatment of asymptomatic disease. These data suggest that the accuracy of self-reported and serological testing for syphilis in HIV-1 seropositive homosexual men with negative RPR is high and the yield of further testing is low.

W.B.P.53 AN ASSOCIATION OF SYPHILIS EPISODES AND HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION IN SEXUALLY TRANSMITTED DISEASE (STD) PATIENTS IN LOS ANGELES COUNTY

Rose, Thomas P.*; Ford, W.*; Kerndt, P.*; Mohilef, E.*; Onorato, I.**
*Los Angeles County Department of Health Services, Los Angeles, California, U.S.A.
**Centers for Disease Control, Atlanta, Georgia, USA.

Objective. To determine if an association exists between a history of syphilis episodes and HIV seropositivity.
Methods. Clients participating in confidential HIV testing in Los Angeles County STD clinics between July 1 and December 15, 1988, were interviewed by pretest counselors about their history of STDs and high risk behaviors such as number of sex partners, drug use, and prostitution.
Results. Having a history of at least one episode of syphilis appears to be strongly associated with HIV seropositivity (p<.0001). For those clients testing HIV positive, 57.8% (26/45) reported an episode of syphilis in contrast to 16.9% of those testing HIV negative (198/1,172). Upon further examination of drug and sex-related risk factors, exchanging money or drugs for sex and intravenous drug use since 1978 were all strongly associated with having had at least one syphilis episode (p<.001). These associations were consistent within race group (Black and Hispanic) and among males. Only exchanging drugs for sex was independently associated with being HIV positive (p<.0001).
Conclusion. Syphilis appears to be a risk factor for HIV infection independent of any confounding effect of intravenous drug use unless drugs are exchanged for sex. Syphilis in Los Angeles County may predispose an individual to HIV infection.

W.B.P.54 "SEROREVERSION" OF TREPONEMAL TESTS DURING HIV INFECTION

Haas, Jennifer S*; Bolan, G**; Larsen, S***; Clement, M*; Moss, A*.
*San Francisco General Hospital & UCSF, SF,CA, **Department of Public Health, SF,CA, ***Centers for Disease Control, Atlanta,GA,U.S.A.

Objective: To evaluate the sensitivity of treponemal tests (i.e.FTA-ABS and/or MHA-TP) for syphilis in individuals with HIV infection.
Methods: *Subjects*—110 homosexual men with a documented history of syphilis, who enrolled in a longitudinal cohort between 1982-85. Syphilis serology done on entry into cohort was compared to records of previous results. Serology confirmed on stored serum samples. *Study design*—retrospective review.
Results: None of the HIV-negative individuals in the cohort "seroreverted," whereas 7.2% of those who were HIV-seropositive but asymptomatic, 42.9% of those with ARC, and 35.7% of those with AIDS had loss of reactivity of a treponemal test. The relative risk of "seroreversion" for those with ARC was 14.3 (p=0.02), and for those with AIDS 10.5 (p=0.02). Characteristics of those with "seroreversion" and those with persistent reactivity include:

	Serorevert n=14	Serofast n=96
T4 count(x10^6/l)	381.2 (215.3-507.1)*	698.4 (627.8-769.1)
T4/T8 ratio	0.54 (0.38-0.69)	0.99 (0.88-1.1)
# episodes syphilis	1.2 (1.0-1.6)	1.8 (1.5-2.0)

*all results reported as mean (+/- 95% confidence interval)

Conclusions: Individuals with symptomatic HIV infection and a documented history of syphilis lose reactivity of treponemal tests. Reversion appears to be related to the decline of total T4 count and T4/T8 ratio. These findings raise questions about the sensitivity of treponemal tests in HIV-infected individuals, and suggest that a history of syphilis cannot be excluded by negative treponemal tests.

W.B.P.55 MENINGOVASCULAR SYPHILIS in AIDS

T. SAINT-MARC*, JL GARNIER*, JM LIVROZET*, JL TOURAINE*, F MEIGNAN**
*Pavillon P Hôpital Edouard Herriot 69 437 Lyon Cédex 03 France.
**E.I.A. DESGENETTES 69 998 LYON ARMEES, FRANCE

HIV may alter the natural history of syphilis by increasing the propensity of the disease to progress to neurosyphilis. Meningeal inflammation induced by either pathogen (HIV and T. pallidum) could allow the other agent to penetrate further into the CNS.

We reported two cases of meningovascular syphilis in homosexual men. One of the two patients had neurosyphilis despite previous adequate therapy for early syphilis with benzathine penicillin.
A 22 year old homosexual was admitted to the hopital with a left facial palsy, a diffuse rash, and a left Hemiparesis, after a three month prodrome of fatigue, headache. He had been treated for one episode of gonorrhea at 18.
Laboratory revealed a VDRL test titer of 1/1024, TPHA test titer of 1/1280 and a positive test for serum HIV antibody. Examination of the CSF revealed lymphocytic Pleocytosis (103 white cells per cubic millimeter), an elevated protein level (0,86 g/l) hypoglycorrachia, a VDRL test titer of 1/16, TPHA test of 1/80 and positive test for CSF HIV antibody and P24 antigen. MRI revealed an infarction of the right hypothalamus area. Patient was treated for 18 days with intravenous penicillin (20 million units per day) and Probenid and had no Jarisch -Herxheimer reaction. We described CSF at J1, J4, J10, J30, J90,. We reported another case of 37 year old man.
This observation illustrate that Syphilis in patients with HIV infection follow a malignant or protracted cause.
Lumbar puncture may be indicated in the Evaluation of HIV seropositive patients with Syphilis, a more aggressive therapy including maintenance therapy.
Neurosyphilis should be added to the growing list of infections complications of AIDS.

W.B.P.56 SEROLOGICAL AND CEREBROSPINAL FLUID PARAMETERS RELATED TO SYPHILIS IN HIV ASYMPTOMATIC SEROPOSITIVES

Joseph R. Berger, M.D.*˚, M. McCarthy*, M.A. Fletcher˚, N. Klimas˚, E. Lo#, L. Pall*.
From the Departments of Neurology*, Internal Medicine˚, and Pediatrics#, the University of Miami School of Medicine, Miami, Florida, U.S.A.

Serological and CSF parameters associated with syphilis were analyzed in asymptomatic HIV-seropositives. Thirty-four of 86 (39.5%) reported a remote history of syphilis. Serum FTA-ABS was positive in 25/34 (73.5%) of those with a positive history and in 4/52 (7.7%) without a history. Only 8 subjects had a positive serum RPR and all of these had a positive history for syphilis. The CSF VDRL was positive in 3/81 (3.7%) asymptomatics, one of whom had never been previously diagnosed with syphilis. The CSF FTA-ABS was positive in 6; 3 of whom had neither a history of syphilis nor a positive serum FTA-ABS. A history of syphilis had no effect on CSF white blood cell count, protein, glucose, immunoglobulin level or the presence of oligoclonal bands.

In our population, a history of syphilis is common and serological confirmation (FTA-ABS) unaffected by concomitant "early" HIV infection. 3.7% of asymptomatic HIV seropositive subjects had unsuspected neurosyphilis as defined by a positive CSF VDRL. Though the CSF VDRL may be relatively insensitive for diagnosing neurosyphilis, the CSF FTA-ABS appears to be too nonspecific. The presence of a CSF pleocytosis, elevated immunoglobulins and oligoclonal bands was equally common in those without as with a history of syphilis. Greater precision in diagnostic modalities is needed to firmly establish the presence of neurosyphilis.

Supported by National Institute of Neurological Diseases and Strokes Program Project P01-NS25569.

W.B.P.57 SYPHILIS TREATMENT RESPONSE IN HIV INFECTED PERSONS

Telzak, E.* **; Zweig, Michele*; Harrison, J.*; Stoneburner, R.*; and Schultz, S*. *New York City Department of Health (NYCDOH), NY, NY, **Memorial Sloan-Kettering Cancer Center, NY, NY, U.S.A.

Objective: To determine whether HIV infected persons treated for primary (PS) or secondary syphilis (SS) have a modified rapid plasma reagin (RPR) response and thus are more likely to be considered treatment failures compared to HIV- patients with a comparable stage of treated syphilis.
Methods: Medical records were reviewed and abstracted on all patients with PS and SS attending NYCDOH STD clinics in a one year period beginning June 1987 during which sera of all positive RPRs were saved. Eligible study participants were those who had RPR titers measured prior to and subsequent to syphilis treatment. Sera were retrieved and tested for HIV. Serologic (RPR) failure and success parameters were analyzed according to HIV status.
Results: Data on 303 (45%) of 677 participants are currently available for analysis. Of these, 124 (41%) had PS and 179 (59%) had SS; 163 (54%) were men and 36 (12%) were HIV positive.

RPR RESPONSE BY HIV STATUS

RPR RESPONSE	HIV+	(%)	N	HIV-	(%)	N
>=4X RPR Increase	2	(6%)	36	6	(2%)	267
Stable or Increasing RPR after 6 months	1	(4%)	36	2	(1%)	267
>=4X RPR Decrease within 6 months	22	(73%)	30	172	(71%)	242

Conclusions: HIV+ and HIV- persons were equally likely to have a fourfold or greater decrease in RPR titer within 6 months of treatment for syphilis. Although HIV infected persons were more likely to have an increasing or stable titer after 6 months or a 4-fold increase at any time, "treatment failure" remains unusual.

W.B.P.58 RETREATMENT OF SYPHILIS IN HIV POSITIVE PATIENTS.

Hay Phillip, Harris J R W, Goldmeier D. The Praed Street Clinic, St Mary's Hospital, London, W2 1NY, United Kingdom.

Objective: Treponemes can persist in the CNS following standard treatment of early syphilis with benzathine or procaine penicillin. Approximately 50% of homosexuals with AIDS have had syphilis, and it is possible that persisting treponemal infection contributes to the neurological manifestations of AIDS. We are performing a trial to assess the benefits of retreatment with an antibiotic regime that achieves good CNS penetration.

Methods: A double-blind placebo controlled trial using amoxycillin 3 g bd/probenicid 500 mg bd for HIV positive patients previously treated for syphilis. All patients have CDC stage 4 disease. They are assessed over 6 months with neuropsychiatric tests, neurological examination and serology.

Results: Nineteen patients have been treated so far. One withdrew due to penicillin allergy, 2 because of admission to hospital. Four patients stopped after 2 weeks because of minor reactions. Twelve completed the 3 week course. So far no significant difference between the treatment and placebo groups has emerged.

Conclusions: These are small numbers of patients but the results of long term follow up will yield more information. Probenicid increases the half-life of zidovudine. This has prevented use of the trial treatment in patients taking zidovudine, until the safety of such a combination is assessed. The amoxycillin and probenicid regime may be useful for the initial treatment of syphilis in HIV positive patients.

W.B.P.59 FAILURE OF BENZATHINE PENICILLIN TO ERADICATE SYPHILIS IN HIV POSITIVE PATIENTS.

Hay Phillip, Kitchen V, Harris J R W, Goldmeier D. The Praed Street Clinic, St Mary's Hospital, London, W2 1NY, United Kingdom.

Objective: An increasing number of reports document failure when using benzathine penicillin to treat early syphilis in HIV positive patients. Alternative regimes that have been suggested include procaine penicillin with probenicid, oral amoxycillin with probenicid, and intravenous benzylpenicillin. We reviewed the progress of 15 patients treated for early syphilis when they were thought to be HIV positive.

Results: Seven patients received benzathine penicillin 2.4 MU repeated after 6 days. Two of these developed tertiary syphilis, in spite of having the treatment repeated. One required IV benzylpenicillin to eradicate a gumma, the other a 15 day course of procaine penicillin 2.5 MU with probenicid 500 mg qds to treat neurosyphilis.

One patient treated with repeated courses of doxycycline developed neurological disease which may have been neurosyphilis, but he died from PCP before the diagnosis was established.

Seven patients received oral amoxycillin 3 g bd with probenicid 500 mg bd. One of these was in the third trimester of pregnancy. The infant was subsequently treated for possible congenital infection. This patient and 3 others receiving amoxycillin declined the HIV antibody test but had a high probability of being HIV positive.

Conclusions: Benzathine penicillin is unreliable for the treatment of syphilis in HIV positive patients. Alternative regimes have not yet been fully evaluated. We are using PCR to look for treponemes in CSF's as a way of evaluating the effectiveness of treatment.

Soins alternatifs, soins traditionnels
Alternative and Traditional Care

W.B.P.60 HIV-RELATED PRIMARY MEDICAL CARE FOR INTRAVENOUS DRUG USERS (IVDU) IN A METHADONE MAINTENANCE TREATMENT PROGRAM (MMTP)

Selwyn,Peter A; Feingold,AR; Iezza,A;Satyadeo,M; Shaw,JF;Torres,R. Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY, USA.

Objective. To evaluate the feasibility of providing on-site HIV-related primary medical care for IVDU's enrolled in a longterm outpatient MMTP in New York City. Methods. IVDU's with or at risk for HIV infection were offered on-site primary medical care at a Bronx MMTP. Patients with AIDS or advanced HIV disease (CDC IV C.2) were offered AZT (from 5/87) and weekly aerosolized pentamidine (from 3/88). Patients with latent or active tuberculosis (+PPD/TB) were offered supervised chemotherapy along with daily methadone doses (from 1/86). Pregnant women were offered HIV antibody (Ab) testing and clinical care for pregnancy (from 9/85). Results. (1) AZT: 33/48(69%) eligible patients accepted AZT, including 15(45%) women. Mean length of treatment through 1/89 was 30 wks.(range 1-81); 13/33(39%) required dosage adjustment; 8/33(24%) stopped AZT due to toxicity (n=6) or non-compliance (n=2). (2) Pentamidine: 19/22(86%) eligible patients accepted weekly pentamidine; 14/19(74%) have continued >3mos., 1/19(5%) stopped therapy.(3) +PPD/TB: 46/56(82%) patients with +PPD accepted INH; 34/38(89%) evaluable patients received ≥ 6 mos. INH; 13/13(100%) evaluable patients with active TB received multidrug therapy ≥ 9 mos. or until death. (4) Pregnancy: HIV Ab testing and on-site care were accepted by pregnant women in 152/214(71%) pregnancies from 9/85-1/89. Conclusion. Results indicate high levels of participation in HIV-related primary medical care among IVDU's in our MMTP, including treatment regimens requiring close follow-up and monitoring. Care is facilitated by patients' frequent clinic visits to receive methadone, which suggests that MMTP's can be effective sites for preventive and therapeutic medical interventions among high-risk IVDU's.

W.B.P.61 REPORT ON A STATEWIDE SURVEY TO DETERMINE LEVELS OF OUTPATIENT CLINIC/AMBULATORY CARE SERVICES FOR PERSONS WITH HIV INFECTION

Young, Steven R.; Grant, Christine M.
New Jersey State Department of Health, U.S.A.

Objective. To determine the configuration and cost of needed ambulatory services for HIV infected persons in New Jersey which has the fourth highest number of AIDS cases and significant HIV seroprevalence.
Method. Data was obtained from a statewide survey of 16 hospital- and community-based ambulatory health centers caring for 2,678 HIV positive clients, a review of Medicaid outpatient charges for HIV infected persons; and the State's HIV Case Management Information System of 1,579 persons during the period Fall 1988.
Results. Previously reported reviews of HIV related care have focussed on inpatient acute care resource consumption. 66% of HIV positive clients report the single biggest unmet need to be ambulatory care. Its rate of growth is several times that of acute care for HIV infected persons. Waiting times for appointments ranged from same day to eight weeks. Referrals to ambulatory services are highest from acute settings, lowest from private physicians, dentists, community agencies including drug abuse facilities. Medicaid is the primary insurer. 11 ambulatory clinical therapies were identified as being the predominant therapies needed as were specific obstacles to expanding services.
Conclusion. Ambulatory care has emerged as most needing additional resources & organization. This is consistent with earlier identification and expanded prophylactic therapy. The NJ Dept. of Health has developed a statewide approach to HIV Ambulatory Care centers to meet the imminent need.

W.B.P.63 COMPREHENSIVE HIV CASE MANAGEMENT PROTOCOLS FOR 26 NORTHERN CALIFORNIA COUNTIES

Patty S. Blomberg*, N. Flynn**, *Sacramento AIDS Foundation; **University of California, Davis Medical School, Sacramento, CA, U.S.A.

Objective. To develop for Northern California area physicians and hospitals HIV education and a comprehensive case management protocol for HIV, ARC/AIDS patients. Northern California has had 600 cases of AIDS recorded since 1983. Projections indicate 1,500 cases of AIDS and over 12,000 HIV cases in the region by 1992.
Methods. Questionnaires, surveys, and site visits, together with epidemiological studies, conducted by the state, the counties, the Sierra Foundation, U. C. Davis Medical School, and the Sacramento AIDS Foundation, found the need and resources necessary and have developed a regionalized HIV/AIDS service plan and comprehensive case management protocol.
Results. A committee assembled in Aug., 1988, under the joint leadership of the Sacramento AIDS Foundation and Dr. Neil Flynn, Director of the U. C. Davis Medical Center, wrote and developed a comprehensive regional case management protocol guide that describes appropriate care and resources needed to address all regional HIV services. Case management for this protocol is defined as the process in which the necessary resources are provided to maintain persons with HIV and AIDS at the highest level of functioning during the course of the disease, beginning with a positive HIV test, and continuing for the rest of the patient's life. The guide includes nine components: 1. AIDS education; 2. AIDS medical care, inpatient, extended care, and intermediate health services; 3. Social service advocacy, including emergency and long-term housing; 4. Hospice service; 5. Spiritual and wellness support; 6. Mental health, outpatient and in-hospital emotional support; 7. AIDS outpatient services, an outpatient regional AIDS treatment center; 8. Nursing, home health and practical support for daily living; 9. Legal services; with, appendices that include resources in the 26-county region. This recently-completed document will be updated every 6 months. The updates will provide the region with the most current medical treatment and drug protocols developed. The treatment algorithm, located at the beginning of the guide, is a quick reference for health care givers to locate their patients' needs at any/all stages of the HIV illness.
Conclusion. The Protocol Guide will assist primary care physicians first by providing update diagnostic and treatment information (it will provide a type of on-the-job continuing education backed by the facility of the University of California, Davis Medical School); secondly, the shortage of primary physicians and health care providers in this primarily rural area of California will be offset by the regional consultation network, growing from the distribution plan of the Protocol Guide.

W.B.P.65 HOME TRANSFUSION: A SAFE, EFFECTIVE ALTERNATIVE TO TRADITIONAL CARE.

Renee L. Peugeot. Atlanta Home Care, Atlanta, Georgia, U.S.A.

Objective: To describe an active, safe and effective home blood transfusion program designed to meet the needs to the HIV + patient experiencing anemia.
Methods: We set up a home blood transfusion program designed to meet the needs of the anemic HIV + patient who often requires 3-4 units of Packed Red Cells per episode. Patients must be cardiovascularly stable and require transfusion on a non-emergent basis. The program is an ideal alternative to the homebound patient who is unable to make repeated trips to the hospital. Packed cells are given consecutively, thereby decreasing total administration time. Patients are continuously monitored by a registered nurse trained to detect possible complications.
Results: (July 87 -Jan. 89)

Total patients	105
Transfusion episodes	432
# RBC units given	1060
Adverse reactions	0

Conclusions: Our home transfusion program has proven to be a safe and effective means of treatment for HIV+ patients. The number of non-acute hospitalizations for these patients has significantly decreased. This has also resulted in decreased medical costs and time lost from the work place.

W.B.P.62 A COLLABORATIVE APPROACH TO PRIMARY OUTPATIENT ORIENTED CARE OF PATIENTS WITH HIV INFECTION

Bartlett, K., Hadley, D., and Jensen, Peter C.
Departments of Nursing and Medicine, Veterans Administration Medical Center and The University of California, San Francisco, California, USA

The San Francisco Veterans Administration Medical Center (SFVAMC) is a 300 bed teaching hospital with a traditional emphasis on inpatient care that is located in an area of high endemicity for HIV infection. The Infectious Diseases Clinics provide primary outpatient care for the majority of HIV-infected patients seen. A multidisciplinary, collaborative model of care was chosen to deal with the complex care issues that emerge in our patients. Collaborative Practice is a model for health care delivery first outlined by the National Joint Practice Commission in 1977. In our clinic, the main elements are: 1) Algorithms by which clinic nurses assume responsibility for most phone and drop-in triage, as well as for many routine clinic visits. Included in these are the assessment of diarrhea and dyspnea symptoms, common dermatologic, dental, and psychosocial issues, and the management of many patients on AZT. 2) Collaborative development of clinic policies, procedures, and goals by representatives of each of the involved allied health professions, and 3) An integral program of clinical research that encourages participation in protocol development and patient recruitment. Additional features of the program include integrated dental and dermatology sub-clinics, an on-line patient data base, and ambulatory intravenous therapy. Ongoing professional collaboration at all levels improves efficiency, productivity, and morale at SFVAMC.

W.B.P.64 VISITING PHYSICIAN SERVICE FOR AIDS PATIENTS IN NASSAU COUNTY.

G. Feleke, S. Forlenza, Bruce D. Agins. AIDS Program, Nassau County Medical Center (NCMC), East Meadow, NY, U.S.A.

Objective. To describe a visiting physician service for AIDS patients in suburban Nassau County.

Methods. Prospective records were kept of patient characteristics and each physician intervention.

Results. In 1988 a visiting physician service for PWAs was created at NCMC and supported by the Robert Wood Johnson Foundation. Because of geographic constraints and lack of public transportation on Long Island, this service was developed with the intent of minimizing trips to overburdened community hospital clinics by providing non-emergent medical care in the home setting. Between July 1988 and January 1989, 104 home visits have been made for 35 AIDS patients in 20 communities in suburban Long Island. An additional 135 visits were made at the county residential drug treatment facility. Of 35 patients seen at home, 7 were terminally ill, 6 were acutely ill, and 22 had ongoing medical problems. Among these 22, 10 have limited mobility because of neuromuscular disease, 3 received home IV therapy, and 7 received medical care for active problems in lieu of clinic visits. In 104 visits, 116 interventions were made: 36 involved therapeutic intervention; 19 resulted in further diagnostic evaluation, 13 in additional medical referrals, 10 in non-medical referrals and 4 in hospital admission; 20 were classified as routine follow-up care. Psychosocial support to PWAs or family members was the sole intervention in 12 visits; pronouncement of death obviated police intrusion for 2 families.

Conclusion. The visiting physician service offers benefits to patients who are terminally ill, physically dependent on others for mobility, or require active monitoring of home therapy. It offers psychosocial support to patients and families directly in the home environment, while relieving pressure on hospital ambulatory care services. This service is a unique response to AIDS in the suburban community with the largest number of PWAs and offers an alternative approach to traditional medical care.

W.B.P.66 AT-HOME CARE OF TERMINAL AIDS PATIENTS.

Garde, C.; Arrizabalaga, C.; Arrizabalaga, J.; Iribarren, J.A.; Zulaica, D. Hospital Nuestra Señora de Aránzazu. Servicio Vasco de Salud. Osakidetza. San Sebastian. Spain.

Objetive: Evaluation of the problems of this new form of care of AIDS patients.

Method: The hospital team included a physician and a nurse who were charged with at-home care of AIDS patients, particularly terminal cases. The number of visits was determined by the patient's individual needs, and the objective of each visit was to offer the necessary medical care, education for health care and disease prevention, and any psychological support required by the patient or his/her family.

Results: From February to December 1988, 18 patients were attended, 8 of whom died, with different diseases: cerebral toxoplasmosis, PML, KS... The number of visits made to each patient was 2-3 per week, of an approximate duration of an hour.

Conclusions:
1. If the domestic circumstances of the terminal AIDS patient present the necessary sanitary conditions and there are persons willing to care for him/her, in our opinion it is preferable that the patient spend his/her last days at home, since this situation is more conducive to the patient's sense of well-being and the family is more satisfied as to having done everything possible for the patient.
2 Prolonged hospital stays can be considerably reduced, which represents an economic savings for public institutions.

W.B.P.67 A SURVEY OF COMPLEMENTARY AIDS/HIV THERAPIES AND SERVICES

Ostrow, David*; Heinrich, M* and Shelton, A**.
*University of Michigan, Ann Arbor, MI USA, **IIT Research Institute, Chicago, IL USA

Objectives: To determine the range of information and services provided by complementary/alternative AIDS/HIV therapy organizations and practitioners, the range of therapies in use beyond standardized medical treatments, and their willingness to participate in a computerized database of complementary therapies.
Methods: A sample of complementary/alternative providers and organizations was obtained through telephone interviews with PWA organizations and holistic health networks. A brief survey was sent to a sample of 105 organizations, practitioners, and information sources requesting information regarding the types of services provided, specific therapies, types of information collected and willingness to participate in a computerized database.
Results: Over half of the organizations and practitioners responded to the survey and all but three of the respondents were interested in participating in the proposed database. These represented practitioners, buyer's clubs, holistic health facilities and community research initiatives who are serving anywhere from a few to several thousands of persons with AIDS/HIV. At least 100 alternative/complementary therapies were identified, including immune enhancing, antiviral, energy/life force, stress reduction, dietary and anti-tumor therapies. Common underlying strategies being endorsed to restore compromised immune system functioning were: toxin removal and correction of cellular malnutrition; restoration of circadian rhythms; mental imaging; and energy field mobilization or balancing.
Conclusions: Persons with AIDS/HIV are utilizing a wide range of complementary /alternative therapies. Much of this activity is coordinated through organizations and practitioners which collect extensive information regarding specific therapies and potential outcomes. Information regarding these therapies can be obtained from cooperative organizations and practitioners for use in patient education and research planning.

Supported by NIH grant 1R43A126966-01.

W.B.P.68 EFFECT OF CARDIOVASCULAR CONDITIONING IN HIV INFECTION

Keyes, Craig; Rodgers,P; Wolbert,J; Marte,C; Kelly,J; Ribble,D.
Bellevue Hospital/Community Health Project, NY, NY USA

OBJECTIVE: Clinical and immunologic evaluation of cardiovascular conditioning in persons with HIV infection.
METHODS: 28 patients(6AIDS, 18ARC, 4PGL) were randomized to 1 of 2 groups for cardiovascular conditioning in a crossover trial of 16 weeks duration. Treatment phase consisted of 3-1hr periods/wk of aerobic exercise training for 8 consecutive weeks. 8 weeks of usual activity constituted non-treatment. Pre-, mid- and post-trial measures of hematologic, immunologic and cardiovascular parameters were performed. Physical and psychological complaints were also recorded.
RESULTS: Using a paired T-test for combined groups, treatment(cardiovascular conditioning) was statistically significant for CD4 cells(mean increase=68, p .005), T4/T8 ratios(mean increase=.072, p .01), serum globulin (mean decrease=.18, p .005), and resting and recovery pulses(mean decrease 10.2 and 18.6 respectively, p .001). No statistically significant differences in CD8 cells, serum albumin or Hgb were observed. Subjects described improved exercise tolerance, decreased fatigue, improved appetite and lower incidence of depression posttreatment, although numbers were not sufficient to achieve statistical significance.
CONCLUSION: Cardiovascular conditioning by aerobic exercise is associated with significant increases in circulating CD4 cell numbers and T4/T8 ratios and with a significant decrease in serum globulin. Duration and extent of effect, mechanisms of action and impact on the natural history of the disease are under investigation in a more extensive trial.

Diagnostic : marqueurs et progression de l'infection par le VIH
Diagnosis: Markers of HIV Infection and Progression

W.B.P.69 CLINICAL VALUE OF A TAC-INHIBITORY ACTIVITY PRODUCED SPONTANEOUSLY BY ADHERENT CELLS OF HIV-INFECTED SUBJECTS.

A. AMMAR, C. CIBERT, A.M. BERTOLI, P. MEYER, C. JASMIN, V. GEORGOULIAS. Oncogénèse Appliquée, (INSERM U268), Hôp. Paul Brousse, 14-16, av. P.V. Couturier, 94804 Villejuif, FRANCE

Objective : Determine the clinical value of a Tac-inhibitory activity produced during HIV infection.
Methods : Peripheral blood adherent cells were isolated from 15 asymptomatic seropositives, 11 LAS, 4 ARC and 5 AIDS patients, and 24h-conditioned media were prepared without any cell stimulation under serum-free conditions. Conditioned medium-mediated inhibition of Tac expression was tested on normal mitogen-activated PBL and both the ID_{50}(ug/ml) and the % of maximal inhibition were determined. ID_{50} represents the quantity of protein to obtain the 50% of the maximum inhibition.
Results : When the ID_{50} was expressed according to the % of maximal inhibition it was observed that a low ID_{50} with a high % of inhibition was associated with more advanced disease than a high ID_{50} and a low maximal inhibition. Nine of 15 (60%), 2 of 11 (18%), 2 of 4 (50%) and 5 of 5 (100%) of asymptomatic, LAS, ARC and AIDS patients respectively produced significant quantities of the inhibitory activity [ID_5 less than 0.2 ug/10^6 cells]. Prospective longitudinal studies in several patients revealed that decrease of the ID_{50} was followed by clinical stage progression of the infection. Treatment of these patients with AZT allowed to an increase of the ID_{50} and a decrease of the % of maximal inhibition. Preliminary results strongly suggest that the production of Tac-inhibitory activity is associated with higher concentrations of soluble IL2-R but not p24 antigen in the patients' sera.
Conclusion : These findings strongly suggest that Tac-inhibitory activity production is a reliable marker of the evolution of the HIV infection towards the full down disease.

W.B.P.70 APPEARANCE OF p24 ANTIGEN AND DECLINE IN T4 CELL COUNTS AS PREDICTIVE MARKERS FOR AIDS

Eyster, M. Elaine* and Goedert, J.**
*Pennsylvania State University, Hershey, PA and **National Cancer Institute, Bethesda, MD, U.S.A.

Objective. To investigate the predictive value of assays for HIV, p24 antigen (Ag), p24 antibody (ab) and gp120 ab compared to T4 cell counts in a cohort of 87 hemophiliacs with an actuarial cumulative AIDS incidence of 26% (± 7% SE) 8 years after ab seroconversion.
Methods. Ag was measured by the Abbott EIA, p24 and gp120 ab by radioimmunoassay, and T cell subsets by flow cytometry.
Results. Ag was detected in 8/74 (11%) of the non-AIDS and 7/13 (54%) of the AIDS patients. The two year actuarial incidence of AIDS was 24% (± 12%) after detection of Ag, 16% (± 9%) after loss of p24 ab, 20% (± 13%) after loss of gp120 ab, 31% (± 8%) after a T4 count <200 cells/ul and 67% (± 18%) after a T4 count <200 cells/ul among those patients positive for Ag. Very low numbers of T4 or T8 lymphocytes, presence of Ag and absence of p24 ab all had some predictive value. However, only Ag (relative hazard 6.0, p=.008) and T4 counts (relative hazard 5.3, p=.002 with T4 count <200 cells/ul) independently predicted AIDS up to 12 months before diagnosis.
Conclusion. The development of Ag or low T4 counts are both strongly predictive of AIDS in HIV-infected individuals. Detection of Ag is highly specific and complementary to the greater sensitivity of low T4 counts. These findings have important implications regarding the planning, management and interpretation of antiretroviral and immunomodulatory therapies. (Supported by NCI Contract N01-CP-85649)

W.B.P.71 CHICAGO/BOSTON COHORTS STUDY: αp24/gp41 ANTIBODY RESPONSE AT HIV SEROCONVERSION

Blaauw, Bernard B.*, Allen, R.**, Falk, L.**, Mayer, K.***, Dawson, G.**, Saltzman, S.***, et al. *Rush-Presbyterian-St. Luke's Med Ctr Chicago, **Abbott Laboratories, North Chicago, ***Fenway Community Health Center, Boston.U.S.A.

Prognostic value of p24 Ag in HIV+ individuals is well established and recent studies have demonstrated that decline of αp24 may precede antigenemia by several years. We have reported previously use of αp24 for staging HIV+ individuals in the Chicago/Boston cohorts. Because of emerging relevance and prognostic potential of αp24, αp24 and αgp41 levels were measured in 6 seroconverters seen in a private clinical practice (Chicago) and 8 seroconverters of a prospective cohort (Boston), established in 1985, with return visits at 6 month intervals. Antibody levels were determined by competitive EIA using recombinant p24 and gp41 proteins. Two patterns of αp24 response were observed: those responding vigorously with αp24 titers of 1100 - 36,000 (n=5) vs. moderate/low αp24 levels of 7 - 260 (n=8); one individual with low αp24 may still be mounting αp24. αgp41 titers of high αp24 responders ranged from 1500 - 38,000 and 4200 - 26,000 in moderate/low αp24 responders. p24 antigenemia was detected in 4 of 6 Chicago seroconverters and 1 of 8 Boston cohort members; p24 antigenemia resolved with mounting of αp24. Average follow-up periods post seroconversion were 12 and 16 months for high and moderate/low responders respectively. Continued monitoring of these patients/volunteers becomes important, for individuals with moderate/low αp24 may show clinical manifestations of HIV infection sooner than vigorous responders.

W.B.P.72 PREDICTIVE VALUE OF CD4+ NUMBERS, LEVELS OF NEOPTERIN AND BETA-2-MICROGLOBULIN AND RISK OF DEVELOPING PNEUMOCYSTIS CARINII PNEUMONIA

Weber, Rainer; Brühwiler, J.; Ledergerber, B., Vogt, M.; Fierz, W. and Lüthy, R. et al.
Department of Medicine, University Hospital, Zürich, Switzerland

Primary prophylaxis of Pneumocystis carinii pneumonia (Pcp), the most frequent life threatening complication in AIDS, is not generally recommended, because the duration of asymptomatic HIV-infection is variable. Predictive indices are required to improve decision making regarding primary prophylaxis.
Objective: To determine the predictive values of CD4+ counts, serum neopterin (NPT) and beta-2-microglobulin (B2M) regarding the risk of developing Pcp.
Methods: CD4+ (n=396), NPT (n=509) and B2M (n=527) from 292 patients were analyzed retrospectively, using life-tables. Median follow-up period was 7.5 months (range:0.1-65). During this period 26 pts had their first episode of a Pcp.
Results: Probabilities of NOT developing a Pcp at different levels of CD4+, NPT and B2M were:

	CD4+ NUMBERS		NEOPTERIN		B2-MICROGLOBULIN	
	$>200/mm^3$	$\leq 200/mm^3$	≤5.0 ng/ml	>5.0 ng/ml	≤4.8 mg/l	>4.8 mg/l
6 mts	.99(.98-1.00)	.66(.54-.80)	.97(.95-.99)	.93(.89-.96)	.95(.93-.98)	.94(.91-.97)
12 mts	.98(.97-1.00)	.44(.30-.65)	.95(.92-.98)	.90(.85-.94)	.94(.92-.97)	.90(.85-.94)
18 mts	.98(.97-1.00)	.39(.25-.62)	.94(.90-.97)	.85(.79-.91)	.94(.91-.97)	.85(.79-.91)
24 mts	.98(.97-1.00)		.93(.89-.97)	.83(.76-.90)	.94(.91-.97)	.78(.70-.88)
	p<0.001		p<0.01		p<0.01	

Conclusions: Serum levels of B2M, NPT and CD4+ numbers are predictive regarding the risk of developing a first episode of Pcp but only CD4+ numbers discriminate to a reasonable extent. Therefore primary prophylaxis of Pcp in pts with CD4+ numbers $\leq 200/mm^3$ should be evaluated in clinical studies.

W.B.P.73 HUMAN IMMUNODEFICIENCY VIRUS (HIV) IgA SERUM ANTIBODIES IN A LONGITUDINAL STUDY OF HIV INFECTION AND SUBSEQUENT PROGRESSION OF THE DISEASE IN HOMOSEXUAL MEN

Levy, E.*; Margalith, Miriam*; Sarov, B.*; Sarov, I.*; Rinaldo, C.**; Saah, A.**; et al.
*Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel; **The Multi-Center AIDS Cohort Study (MACS), Bethesda, MD, USA.

Objective. To determine the value of serum specific HIV IgA antibodies as a predictor of the progression of HIV infection.
Methods. A sensitive solid phase, enzyme linked immunosorbent assay (ELISA) has been adapted. Microplates coated with a mixture of 4 peptides which correspond to the serological active epitopes of the virus P18, P24, gP41, and gP120 served as antigen (Biochrome K.G.). The serial serum specimens, blindly tested, were obtained from a cohort of 211 homosexuals: 123 HIV seropositives [41 asymptomatic, 29 w/lymphadenopathy associated syndrome (LAS), 22 w/AIDS related complex (ARC), and 31 AIDS patients], 17 HIV seroconverters and 71 HIV seronegatives [36 asymptomatic and 35 w/LAS].
Results. During HIV IgG seroconversion, 47% of the homosexuals developed specific HIV IgA antibodies. HIV IgA antibodies with a titer $\geq$50 were detected among 27% of the HIV seropositive asymptomatic subjects, 25% of LAS and 23% of ARC patients. The prevalence of virus-specific IgA antibodies (titer $\geq$50) among the AIDS patients (55%) was significantly higher as compared with the HIV seropositive asymptomatic subjects (26%) ($p=0.015$).
Conclusions. 1) HIV seroconversion was followed by acquisition of virus specific IgA antibodies in 47% of the seroconverters; 2) Progression of HIV infection in asymptomatic HIV carriers to LAS and ARC was not accompanied by a higher prevalence of HIV specific IgA antibodies; 3) AIDS patients are characterised by high prevalence rates of HIV IgA antibodies.

W.B.P.74 T-CELL SUBSET, B_2 MICROGLOBULIN, AND NEOPTERIN LEVELS IN EDINBURGH HAEMOPHILIACS

Cuthbert, Robert J.G.*; Ludlam, C.A.*; Beatson, D**; Steel, C.M.**
*Dept. of Haematology, Royal Infirmary of Edinburgh, Scotland, **MRC Clinical and Population Cytogenetics Unit, Edinburgh, Scotland.

Objective To assess the value of B_2 microglobulin, neopterin and T-cell subset estimations in predicting clinical progression to serious HIV disease in a cohort of haemophiliacs.
Methods Longitudinal study of 18 HIV seropositive haemophiliacs since seroconversion in 1984, following exposure to a batch of HIV-contaminated factor VIII.
Results Declining CD4 values were observed in all patients, except two who had low values when first studied. The risk of progression to CDC Grp IV disease at 4 years increased significantly at CD4 counts $< 0.35 \times 10^9/l$, RR=16, $p=0.025$; and most dramatically at CD4 $< 0.2 \times 10^9/l$, RR=28, $p=0.07$. No significant changes in CD8 values were observed. Rising levels of B_2M were observed in all patients and this was most pronounced in the symptomatic group. At $B_2M > 3.0$ mg/l the risk of progression to CDC Grp IV was significantly increased, RR=10, $p=0.02$. Rising neopterin levels were observed in 10 of 17 patients. At neopterin $>$15 nmol/l the relative risk of progression to CDC Grp was 5.8, $p=0.11$. Dramatically elevated levels ($>$ 35 nmol/l) were observed in 2 patients with AIDS and 2 with severe ARC, but in no asymptomatic patients.
Conclusion Estimation of CD4 counts, B_2 microglobulin and neopterin levels are useful in predicting the progression of HIV disease in haemophiliacs.

W.B.P.75 IFN-α PRODUCTION, CORRELATION WITH CIRCULATING IFN-α ANTIGENEMIA P 24 AND SEROLOGICAL PROFILE IN HIV$_1$ INFECTED PATIENTS AT DIFFERENT CLINICAL STAGES.

A. Ruffault, H. Gomelet, C. Michelet, O. Guisthau, F. Cartier, B. Faucmmier*.
* Lab. Virologie, CHU ; ** CRTS ; *** Maladies Infectieuses, CHU ; RENNES - FRANCE .

The aim of this work was to investigate the interferon system, both stimulated and circulating IFN-α and to correlate these markers to antigenemia P 24 and decline or lack of antibodies to Gag (P 18 - P 24 - P 55) and or to Pol (P 34 - P 68) antigens, in a attempt to predict the evolution and risk for opportunistic infections . Peripheral mononuclear cells (PBMc) were stimulated with Sendai virus for IFN-α production . IFNs were tested by bioassay (inhibition of viral cytopathic effect on MDBK cells), HIV antigenemia by ELISA and HIV antibodies by immunoblotting .

	IFN-α production Non responder titer < 2.40 log 10 IU/ml	Circulating IFN-α > 0.8 log 10 IU/ml	HIV Ag P 24	Decline or lack of antibody bands	
				Gag Ag	Pol Ag
Controls	0/30 (10 %)	4/28 (13.7 %)	NP		
HIV + patients					
CDC II	7/48 (14.6 %)	10/28 (35.7 %)	NP	8/24	3/24
CDC III	7/27 (25.9 %)	9/30 (30 %)	1/23 (4.3 %)	3/22	7/22
CDC IVa	14/16 (87.5 %)	18/23 (78.2 %)	13/23 (56.5 %)	14/22	18/22
CDC IV (c.d)	8/8 (100 %)	18/18 (100 %)	16/18 (88.8 %)	15/18	13/18

These results show :

- A diminished capacity of PBMc from CDC IVa and CDC IV c.d patients to produce IFN-α ($P < 0.001$).
- A good correlation between circulating IFN-α, antigenemia P 24 and diminished capacity of PBMc to produce IFN-α. * In many cases decrease in P 68 antibody band prior to decrease in P 24 band. These findings suggest that a drop in PBMc stimulated interferon-α in HIV$_1$ seropositive patients could be of value for predicting desease progression .

W.B.P.76 COMPARISON OF ACTIVATION MARKERS FOR PROGRESSION TO AIDS.

Di Franco, Matthew J.*; Berger, C.**; Friedman-Kien, A.***; Edelson, R.****; McLane, M.* and Marlink, R.*.
*Harvard School of Public Health, Boston, MA, **Columbia University, N.Y., NY, ***New York University, N.Y., NY, ****Yale University, New Haven, CT, U.S.A.

Objective. To assess progression to AIDS using markers of immune activation.
Methods. 60 gay men had serum neopterin (NEOP), a marker of macrophage activation, and beta2 microglobulin (BETA2) measured with a subset of men assessed for T4/T8 and BE2, a T4 cell antigen elevated in ATL, CTCL and AIDS.
Results. NEOP and BETA2 were highly correlated in the control and the AIDS groups but not in ARC. T4/T8 and BETA2 were each significantly different for controls vs. ARC and controls vs. AIDS, but not for ARC vs. AIDS. Mean NEOP and BE2 were also different for ARC vs. AIDS, at $p < .0001$ and $p < .005$.

Means	Controls			ARC			AIDS		
	mean	s.d.	N	mean	s.d.	N	mean	s.d.	N
NEOP (nmol/l)	6.0	(3.5)	12	17.2	(6.3)	10	44.3	(34.2)	37
BETA2 (mg/l)	1.65	(0.67)	13	3.57	(1.43)	10	3.75	(2.12)	36
BE2 (% of total T)	0.69	(0.62)	13	2.57	(2.58)	9	7.82	(8.78)	31
T4/T8	1.93	(1.11)	13	0.62	(0.34)	8	0.53	(0.45)	18

Correlations	Overall			Controls	ARC	AIDS
	BE2	NEOP	BETA2	BETA2	BETA2	BETA2
BE2	1	.43***	.42***	.006	-.17	.38*
NEOP	.42***	1	.78****	.81****	.09	.82****
T4/T8	-.22	-.39*	-.42**	.005	-.39	.13

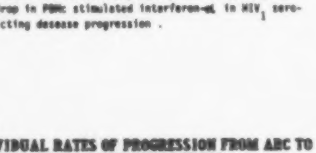
* p <.05 ** p <.01 *** p <.005 **** p <.0001

Conclusion. While each of 4 markers was sensitive for distinguishing between controls and ARC in this group of gay men, serum neopterin combined with % BE2 distinguished between ARC and AIDS better than BETA2 and/or T4/T8.

W.B.P.77 FORECASTING INDIVIDUAL RATES OF PROGRESSION FROM ARC TO AIDS USING ROUTINE CLINICAL LABORATORY TESTS

Kvitash,V. I.* and Schmidt, Robert M.**. Center for Preventive Medicine and Health Research, *San Francisco State University and *Pacific Presbyterian Medical Center, San Francisco, California, USA.

Objective. To develop a diagnostic procedure which definitively predicts the rate of progression of an individual with ARC to clinical AIDS.
Methods. In a prospective study of 30 ARC patients 6 immunological and 7 metabolic parameters were analyzed by Immuno-Balascopy (IBa), an artificial intelligence system for cognition of interactions between and within laboratory analytes. These Immuno-Balascopic patterns were used to predict progression to clinical AIDS in these 30 ARC patients followed for 30 months.
Results. Of the initial 30 ARC patients entered into the study, 6 progressed to clinical AIDS, 11 did not develop AIDS and 13 were lost to follow-up after 30 months. IBa analysis of the AIDS-resistant ARC patients and those progressing to AIDS provided correct identification of all 17 patients remaining in the study. Representative individual IBa patterns for these two groups are shown:



AIDS-RESISTANT ARC ARC PROGRESSING

Conclusion. Definitive identification of AIDS-resistant individuals among ARC patients can be done by IBa based on routine clinical laboratory tests at the time of initial presentation with ARC. IBa can eliminate a minimum of 30 months of prognostic uncertainty for patients with AIDS-related conditions.

W.B.P.78 INCREASED β_2-MICROGLOBULIN CONCENTRATIONS IN CHILDREN WITH AIDS

Chan, Maria; Josephs, S.; Morales, A.; Campos, J.M.; and Rifai, N.
Children's Hospital National Medical Center and The George Washington University School of Medicine, Washington, D.C. U.S.A.

Objective. To determine whether serum β_2-microglobulin (β_2m) concentrations can be a sensitive marker for HIV infection in children, particularly infants, born to HIV-infected mothers.

Methods. β_2m is measured using an immunoturbidimetric procedure.

Results. Sera from 35 patients were tested in this study. Nine patients, aged 1 to 6 years, were HIV-seropositive and symptomatic with decreased cellular responses, absolute CD4 values and inverted T4/T8 ratio. The mean and standard deviation (SD) of β_2m concentrations for this group were 2.67 ± 0.73 mg/L (1.74 to 3.96 mg/L). Eighteen age-matched seronegative patients had a mean and SD β_2m concentrations of 0.98 ± 0.54 mg/L (0.04 to 1.85 mg/L). The difference between the two groups was highly significant by unpaired student t-test ($p<0.0005$). Eight patients, who were HIV-seropositive as determined by EIA but had indeterminant results by western blot analyses, were also examined. Four of these patients had β_2m concentrations similar to the seronegative controls (0.59, 1.40, 1.29 and 1.20 mg/L) and were clinically asymptomatic. Considering that age of these subjects was 1 year or less, it is likely that the antibodies detected were from the mother. The other four had high β_2m concentrations (3.19, 3.29, 4.23 and 6.85 mg/L), symptoms of immune dysfunction and were recently found to be p24 antigen positive. Therefore, the latter four patients were most likely HIV infected.

Conclusion. Based on these preliminary data, serum β_2m concentrations can be used as an indicator for HIV infection in children.

W.B.P.79 NEOPTERIN AS PREDICTIVE MARKER FOR DISEASE PROGRESSION IN HUMAN IMMUNODEFICIENCY VIRUS-1 INFECTION

Fuchs, Dietmar*; Spira, T.J.**; Hausen, A.*; Reibnegger, G.*; Werner, E.R.* and Wachter, H.*.
*University of Innsbruck and Ludwig Boltzmann Institute of AIDS-Research, A-6020 Innsbruck, Austria. **Center for Infectious Diseases, Atlanta, GA, USA

Objective. The value of urinary neopterin levels for disease progression was determined in HIV-1 infected patients.
Method. 68 HIV-1 seropositive homosexuals with lymphadenopathy syndrome were tested for urinary neopterin and T-cell subsets in 1982/83. Their AIDS incidence rate was evaluated in May 1988.
Results. Overall, 21/68 (30.9%) patients progressed to AIDS, with a yearly progression rate of 4 to 9%. The predictive value of urinary neopterin was higher (p=0.0042) than that of CD4+ T-cell counts (p=0.015) or CD4+/CD8+ ratio (p=0.022). Multivariate regression analysis revealed neopterin and CD4+ T-cell counts as significant joint predictors. CD4+ T-cell/neopterin ratio resulted as best predictor of AIDS onset (p=0.0003).
Conclusion. Neopterin predicts better than T-cell subsets the AIDS outcome in HIV-1 seropositives during our study period of 5 years. Combination of neopterin with CD4+ T-cell counts further improved the predictive value. Neopterin is produced by human macrophages activated by interferon gamma. The results indicate a correlation between the level of T-cell/macrophage activation and the progression of HIV-1 infection.

W.B.P.80 PERSISTENCE OF GOOD E-CR1 ACTIVITY RELATES TO NON-PROGRESSION OF IMMUNE DYSFUNCTION IN HIV POSITIVE INDIVIDUALS.

Lange, Michael, Inada, Y., Bukovici-Klein, E., Ramey, W., Cooper, L.Z., Grieco, M.H.; St. Luke's-Roosevelt Hospital Center, Columbia University, New York, New York, U.S.A.

Objective. The Erythrocyte complement 3B receptor (E-CR1) is postulated to provide a cofactor role for the factor I in the inactivation of Complement 3B (C3B) thereby preventing (i) amplification of the positive alternate complement loop and (ii) activation of the terminal complement cascade. In addition E-CR1 binds complement coated (opsonized) circulating immune complexes and infectious particles, shuttling them to phagocytes for elimination. We previously reported our observation on a relationship between low or absent E-CR1 activity with triple positive Coombs test and progression to AIDS in prospectively followed HIV positive (Htve) volunteers. We here present data to show a direct relationship between normal E-CR1 activity in HIV positive individuals observed prospectively over 7 years who have shown no clinical or immunological deterioration based on absolute T4 cell counts.
Method & Results. Of 108 homosexuals prospectively followed since 1981/82, 60 were HIV seropositive (H+) and 42 seronegative (H-) on entry. An additional 6 have seroconverted. Of 54 H+ on whom E-CR1 was measured biannually beginning in 3/83, 25 have developed AIDS and 5 ARC. Of these, 24(80%) had 25% or less CR1 activity in 1983 and all had decreasing CR1 activity at least 12 months prior to development of clinical illness. 24 remained clinically asymptomatic and of these 7 have not shown any significant decrease of CD4 T cell numbers over the 7 years observation period. Of these all had normal initial E-CR1 activity (75% to 100% of control) and had 100% normal CR1 function at all follow-up time periods tested.
Conclusion. The persistence of an asymptomatic state and nondeterioration of absolute CD4 cell numbers in volunteers HIV seropositive for at least 7 years correlates strongly with the persistence of normal E-CR1 function, suggesting that the physiological role of E-CR1 function plays a role in the immunopathogenesis of HIV infection.

W.B.P.81 SERUM B2M IN INTRAVENOUS DRUG ABUSERS WITH HIV INFECTION.

E.H.Cooper*, M.A.Forbes*, S.Sutherland**, T.J.MacManus**

*University of Leeds, Leeds, England; **PHLS, Dulwich Hospital, London, England. UNITED KINGDOM

Objective. To determine whether IVDA influences serum beta-2-microglobulin distribution in HIV infection that may interfere with its interpretation as a prognostic index to determine the risk of progressing to AIDS.
Methods. Sera referred to the PHLS were measured by the Pharmacia B2M-RIA.
Results. The patients were sub-divided into anti-HIV antibody +ve or -ve, and whether they had symptoms (PGL was classified as symptomatic, 3 patients with Stage IV AIDS, B2M 1.6, 3.1 and 6.1 mg/l; and 3 with renal failure, B2M 15.3, 11.7 and 8.9 mg/l were excluded).

			B2M (mg/l)		
Symptoms	HIV	No.	Mean	SD	%>3
Nil	-ve	132	1.6	0.6	4
Present	-ve	35	2.2	0.7	20
Nil	+ve	28	2.4	0.65	25
Present	+ve	18	2.9	1.1	44

Conclusions. IVDA per se has no significant effect on the B2M level. HIV infection is associated with a rise of B2M; transient rises may be the result of coincidental viral infections.

W.B.P.82 [1-^{14}C] ARACHIDONIC ACID RELEASE FROM HUMAN CD$_4^+$ MONOCYTIC U 937 AND CD$_4^+$ T-LYMPHOCYTIC CEM CELL LINES IN THE EARLY STAGE OF HIV INFECTION

Dray, Fernand ; Renard, C.A. ; Guétard, D.* ; Errasfa, M.** ; Vulliez-Le Normand, B. ; Massiet du Biest, B. and Montagnier, L.*
U.207 INSERM, URIA ; *Unité d'Oncologie Virale ; **Unité de Pharmacologie Cellulaire - Institut Pasteur, Paris, France.

Phospholipids (PLs) of cellular membranes require an appropriate percentage of unsaturated fatty acids in the various lipids to maintain their structural and functional characters. This percentage is mainly influenced by phospholipase activities (PLA). Such PLA should be studied in the different cells of the immune system involved in AIDS. For this purpose, human monocytic U 937 and T-lymphocytic CEM cell lines were equilibrated for 1 h or overnight at 37°C with [1-^{14}C] arachidonic acid (*AA). Then, both cell lines were infected with HIV$_1$ or HIV$_2$ (10.000 cpm reverse transcriptase activity per 1X10^6 cells). After 6 h, the radioactivity (*R) was measured in the supernates (SN) directly or after lipid extraction and rp-HPLC. The study of *R in the cell pellets was evaluated by TLC.
Results. The *R measured in SN of U 937 cells infected with HIV$_2$ was significantly increased when compared to non-infected controls. A lesser effect was observed with HIV$_1$. However, infection of CEM cells with either HIV$_1$ or HIV$_2$ showed no significant difference in the release of the *R. About 80% of recovered *R was eluted as non transformed *AA. The increase of *R observed with HIV$_2$ was suppressed in the presence of $6x10^{-8}$ M EGTA, suggesting the involvement of PLA$_2$ activation. The repartition of AA in the various phospholipids and neutral lipids did not reveal major differences between infected and non infected U 937 or CEM cells.

W.B.P.83 EVALUATION OF BETA-2-MICROGLOBULIN AND NEOPTERIN AS PROGNOSTIC MARKERS IN HIV DISEASE

Sandström, Eric; Karlsson, A. and Holmberg, V.
The Guy Mens Health Clinic, Södersjukhuset, Stockholm, Sweden.

Objective. A study was designed to elucidate the usefulness of Beta-2-microglobulin (β2m) and Neopterin in predicting disease progression to ARC and AIDS.
Methods. A total of 1198 frozen serum samples, collected during 1983-88 in Stockholm from 185 homo- and bisexual men who were or turned HIV seropositive, were analyzed for β2m and Neopterin. Single samples from 59 HIV negative men were analyzed as controls. The marker levels were statistically (Student's t-test) compared in relation to CDC classification.
Results. Mean β2m-values in comparison to CDC classification (nr. of observations in brackets).

Negatives		CDC-classification							
Contr.	Preconvers.	II	III	IV-z**	IV-γ*	IVA	IVC1	IVC2	IVD
1.32	1.54	2.18	2.22	2.57	2.79	3.65	3.25	2.78	3.47
(59)	(53)	(112)	(94)	(19)	(19)	(10)	(6)	(14)	(3)

* β2m value measured within 3-6 months prior to first visit with stage IV **β2m prior to IV-γ

For β2m statistically significant differences were noted between the negative values and all positive values. Furthermore, the values in asymptomatic patients (CDC stage II/III) differed significantly from those in symptomatic patients (CDC IVA-D). Neopterin failed to show any significance between the negative and the II+III values but gave the same pattern of significant differences as β2m for asymptomatic and symptomatic patients. A great variability in Neopterin levels between visits was frequently detected.
Conclusion. Although corresponding rises in β2m and Neopterin correlated with the disease progression a lesser degree of variability would favour β2m as a prognostic marker.

W.B.P.84 INCREASED PROLIFERATION OF ORAL EPITHELIAL CELLS IN HIV-INFECTED PATIENTS.

Langford, Angelika[1]; Kunze, R.[2], Ehm, I.[2], Pohle, H.D.[3], Reichart, P.[1]
Free University[1], Robert-Koch Inst.[2], Rudolf-Virchow Univ., D-1-Berlin 65, FRG.

Objective: To determine the proliferation of oral epithelium in patients in different clinical stages of HIV infection.
Material and methods: Mouth washes (10 ml PBS) of 20 HIV seropositive patients (asympt. n=5, ARC: n=7, AIDS n=8) and of 20 HIV seronegative persons were obtained under standard conditions. The oral epithelial cell suspensions (c.s.) were washed, filtered and fixed with acetone. The cells were incubated with a monoklonal antibody specific for Kl1 keratinocyte in indirect fluorescence technique. The cells were analysed by flowcytometry. In some cases the results were visualized using the immunocytochemical APAAP technique.
Results: In all c.s. of control persons the amount of KL1+ cells was lower than 5%, while in HIV+ patients the percentage of positive cells was more than 15 %.
Kl1 positive cells in c.s. of HIV+ patients showed a broad spectrum of fluorescence intensity, pointing to the different size of the keratinocytes. No correlations to the clinical stages of HIV-infection were stated.
Conclusion: The demonstrated non-invasive technique seems to be a valuable tool to quantify the proliferation rate of oral epithelial cells. The role of the increased proliferation of oral keratinocytes in HIV-infected patients in regard to a later defect in the barrier function of the oral mucosa is yet unknown.

W.B.P.85 MEASUREMENT OF β2-MICROGLOBULIN (β2M) BY RATE IMMUNO-NEPHELOMETRIC ASSAY IN BLOOD FROM AIDS PATIENTS

Khayam-Bashi, Hassan; Johnson, M.; Chen, K.; and Wilber, J. Clinical Labs, S.F. General Hospital and Dept. Lab Med., UCSF, San Francisco CA.U.S.A.

Objective: β2M content of blood, CD4 T-cell count, hemoglobin and social and behavioral risk factors have been proposed as prognostic indicators in AIDS/ARC patients. We developed a method to measure β2M by immunonephelometry (INA).
Methods: We used the Beckman ICS nephelometer and commercially available anti-β2M. We mixed 50 µl of serum or plasma with 1.50 ml of 9% polyethylene glycol (PEG) and 84 µl of anti-β2M. β2M from human urine was used as standard.
Results: Analytical sensitivity and linearity were 1.0 mg/L and 7.7 mg/L. Inter-assay CV's were 7.2% for 5.6 mg/L and 6.0% for 2.6 mg/L. Intra-assay CV's were 3.9% for 6.7 mg/L and 4.0% for 2.3 mg/L. β2M content by EIA (Pharmacia) and INA were highly correlated; r = 0.926. Sera from 45 AIDS and ARC patients had a mean β2M of 3.7 ± 1.6 mg/L. Sera from 22 healthy subjects had a mean β2M of 1.7 ± 0.3 mg/L. Lipemic specimens were cleared by ultracentrifugation. Specimens kept at -70 °C up to 6 months are suitable for this assay.
Conclusion: This INA procedure is easily adaptable to routine clinical laboratory operation, is less expensive and is less labor-intensive than is ELISA and RIA. Further, the AIDS/ARC β2M shows significant elevation over healthy subjects studied at SFGH.

We wish to acknowledge Dr. A. Moss for providing AIDS/ARC samples.

W.B.P.86 THE CLASSIFICATION OF HIV DISEASE: CORRELATION OF BETA-2-MICROGLOBULIN (B-2-M) AND ERYTHROCYTE SEDIMENTATION RATE (ESR).

Kilborn, J; Fisher, Evelyn J; Markowitz, N. and Saravolatz, L.D. Henry Ford Hospital, Detroit, Michigan, USA,

Objective. To identify the role of beta-2-microglobulin, erythrocyte sedimentation rate, and hemoglobin (Hb) as predictive indicators of CDC-HIV stages.
Methods. At the time of initial medical assessment, 70 HIV(+) men were classified according to CDC clinical stage and had serum B-2-M, ESR, Hb and CD2, CD4, and CD8 T-lymphocytes subsets determined. CDC groups were then compared by analysis of variance.
Results. Mean values ± standard deviations are indicated for each parameter.

CDC Group	N	ESR	B-2-M	Hb	CD4	%CD4	CD4/CD8
II	15	12.5±11.7	2.6±0.9	15.4±1.0	597±431	28.0±12.4	0.67±0.49
III	43	15.2±15.4	2.4±0.6	15.1±1.4	517±269	27.4±11.0	0.66±0.36
IV	12	53.0±44.3	3.9±2.3	13.7±2.3	290±180	17.0± 7.9	0.36±0.22
P value		0.0002	0.003	0.02	0.03	0.02	0.05

When analyzed by disease stage, none of the above parameters differed between groups II and III; all were significantly different between groups III and IV. Among T-cell measures, %CD4 correlated best with group. However, ESR, B-2-M and Hb were each a more sensitive predictor of Stage IV than %CD4.
Conclusion. The B-2-microglobulin and ESR may be more sensitive than the T-cell markers and a less expensive means in monitoring HIV disease.

W.B.P.87 QUEST FOR PROGNOSTIC MARKERS IN HIV INFECTED HAEMOPHILIAC CHILDREN

Susan Skidmore*, MD Williams**, SJ Mawson* & FGH Hill**
*Regional Virus Laboratory, East Birmingham Hospital, Birmingham, UK
**Department of Haematology, Birmingham Children's Hospital, UK

Objective: To assess the predictive value of laboratory markers in progression of HIV infection in a cohort of haemophiliac boys.
Methods: Assays for anti-HIV, anti-p24 antibody, p24-antigen, α-interferon, neopterin and B2-microglobulin were bought in kit form and carried out according to the manufacturer's instruction.
Patients: Since the introduction of HIV screening, HIV seroconversion has been shown in 34 haemophiliac boys attending a large paediatric haemophilia centre. It has been possible to document that seroconversions occurred as early as 1981 but the majority in 1983 to 1985 with seroconversion precisely identified within a three month period in at least a third of the patients. Sequential samples including some pre-seroconversion are available on all patients (mean number 13 per patient).
Results: Among this cohort one boy who has persistent α-IFN had one episode of pneumocystis carinii pneumonia 2 years ago, but is currently well on no treatment. Although a further 7 boys have one or more altered markers, all remain well and are asymptomatic, some after 8 years of follow up. These results will be presented in relation to the time from seroconversion.
Conclusion: Results from marker studies in haemophiliac children should be interpreted independently. Data from studies in adults cannot be used to predict the course of infection in children. It seems likely that age will prove a contributory factor in the development of the infection in this group of patients.

W.B.P.88 ROUTINE LABORATORY TESTS WHICH CORRELATE WITH HIV-1 INFECTION PRIOR TO ONSET OF AIDS

Wallace, Joyce I.*,***; Beatrice, S. **; and Sacks, H.S.***, *Foundation for Research on Sexually Transmitted Diseases, NY, NY, USA; **New York City Department of Health, NY, NY, USA, and ***Mount Sinai School of Medicine, NY, NY, USA

Objective: To identify routine laboratory tests whose results can correlate with HIV-1 infection in asymptomatic people.
Methods: A group of 110 apparently healthy, formerly drug addicted women was evaluated during 1983-1985. The relationship of routine laboratory tests to anti-HIV-1 antibody presence was evaluated by univariate and multivariate analysis. HIV-1 testing by ELISA with confirmation by Western Blot found 46 of these women to be positive for anti-HIV-1 antibodies. None had AIDS or ARC at the time of evaluation.
Results: Even in the asymptomatic stages of the disease process, there is evidence of statistically significant values ($p < 0.05$) in increased globulins (Glob), and decreased albumin (Alb) and albumin/globulin ratio (Alb/Glob), hematocrit (Hct), white blood count (WBC), lymphocytes (Lym), cholesterol (Chol), sodium (Na), iron (Fe) and calcium (Ca) levels in the anti-HIV-1 positive women (values expressed as Means with Standard Deviation):

Status	n	Glob	Alb	Alb/Glob	Hct	WBC	Lym	Chol	Na	Fe	Ca
HIV +	46	3.74	3.92	1.089	37.65	5,553	2,004	156.89	136.52	74.95	8.86
HIV -	64	3.04	4.11	1.396	39.24	7,024	2,317	184.85	138.05	88.30	9.03
StDev+		0.72	0.34	0.227	3.57	1,437	535.9	39.78	2.35	27.16	0.39
StDev-		0.55	0.31	0.293	3.58	1,948	581.5	39.04	2.69	36.74	0.36

Conclusion: This profile of results is indicative of the pattern of early malabsorption common to ARC and AIDS. The clinician can be alerted to suspect HIV-1 infection in these early stages, prior to the onset of ARC, by detecting this pattern of high globulins with "low normal" chemistries and blood counts. This pattern needs to be confirmed in other populations.

W.B.P.89 NEOPTERIN IS A RELEVANT DIAGNOSTIC MARKER IN HIV-INFECTION.

E. Reisinger *, P. Kern *, S. Schwander *, A. Dörlemann *, H. Ernst +, D. Berzow **, A. Plettenberg §, H.D. Flad +, M. Dietrich *.

* Clin. Dpts. and ** Dpts. of Virology, Bernhard-Nocht-Inst. for Tropical Med., Hamburg, FRG,
+ Forschungsinstitut Borstel, FRG
§ Dpts. of. Dermatol. AK St. Georg, Hamburg, FRG

Objective. Neopterin is produced by gamma-interferon stimulated macrophages. We report on the correlation of serum-neopterin with the course of HIV-infection during a prospective randomized double blind treatment study. Methods. 54 patients were examined in 6-weeks intervals and the neopterin levels were correlated with known prognostic markers for HIV-infection. In the RIA we are using, the upper normal limit is 10 nmol/l. Results. In the asymptomatic stage of the HIV-infection the neopterin levels are normal in most cases. In early symptomatic stages of infection (CDC III) the neopterin levels are elevated minimally (10-20nmol/l). The levels tend to increase with progression in CDC, Walter-Reed and Zolla-Pazner stages. No increase is seen in case of local superficial irritation (e.g. hairy leucoplakia, oral thrush). But there is a stringent correlation with the generalized infections associated with HIV (e.g. severe opportunistic infections, herpes zoster etc.). Neopterin is also highly correlated with progression parameters as CD4 pos. lymphocytes, CD4/CD8 ratio, and HLA-DR pos. lymphocytes.

W.B.P.90 THE USE OF SERUM OLIGOCLONAL IMMUNOGLOBULINS TO MONITOR THE COURSE OF HIV-INFECTION.

Papadopoulos, Nicholas*, and Costello, R.*
*National Institutes of Health, Betheeda, Maryland, USA.

Objective. To use oligoclonal bands as markers to follow the course of HIV-infection.
Methods. The increased sensitivity of our zone electrophoresis technique to determine serum proteins demonstrates discrete oligoclonal immunoglobulin bands (OIB) within an intense diffuse γ-globulin zone. Originally OIB were found in the serum of HIV-antibody carriers. Subsequently the serum OIB were identified with HIV-antigens. Presence of OIB in the serum of HIV-antibody carriers indicates a specific immune response of the host to HIV infection. This electrophoresis technique is used to monitor OIB in serum samples of asymptomatic HIV-antibody carriers. Testing is done every six months to correlate persistence and disappearance of OIB with progression of HIV infection to AIDS.
Results. Serial analysis of serum samples from 68 HIV-antibody carriers was performed for three years. During this period in 14 of 68 carriers (20%) disappearance or absence of OIB was associated with the development of clinical AIDS.
Conclusion. Millions of people worldwide are infected with HIV. Little is known about the factors that influence progression of infection to AIDS. Determination of OIB at defined time intervals serves as a useful marker to follow the clinical course of the infection in its progression to clinical AIDS.

W.B.P.91 CSF NEOPTERIN IN HIV-1 INFECTION AND AS A FUNCTION OF AIDS DEMENTIA COMPLEX (ADC) SEVERITY

Brew, Bruce J; Bhalla, R; Schwartz, M; Price RW. Memorial Sloan-Kettering Cancer Center, New York NY USA

Objectives: To determine the clinical significance of elevated concentrations of neopterin in the cerebrospinal fluid (CSF) of HIV-infected individuals and assess the value of CSF neopterin as a marker of ADC.
Methods: 50 samples of CSF and serum from 44 neurologically symptomatic patients at various stages of HIV infection were analysed by radioimmunoassay (a gift from Kallestad) for neopterin and albumin (CSF and serum). All patients had been assessed by a neurologist and staged according to the presence and severity of ADC.
Results:

Neurological Diagnosis	# Pts	CSF Neopterin (nmol/l±SD; normal<3.4)	Serum Neopterin (nmol/l±SD; normal<10)
CNS Lymphoma	3	54.3 ± 27.1	37.3 ± 29.1
CNS Infections	4	71.7 ± 59.3	79.5 ± 63.4
ADC	28	29.8 ± 26.0	33.2 ± 33.0
Headache	9	17.3 ± 11.5	27.0 ± 25.3

In the ADC only patients, CSF neopterin correlated with ADC severity (p=.001) but not albumin ratio.
Conclusions: CSF neopterin is frequently elevated in HIV-infected individuals and as such is non-specific. In those patients with ADC without other confounding illnesses, CSF neopterin correlated with ADC severity and seemed to be independent of blood-brain barrier dysfunction. As such, it may prove useful as a marker of ADC when other confounding illnesses are absent.

Diagnosis: HIV

W.B.P.93 EFFICIENT SCREENING FOR HIV 1- AND HIV 2-ANTIBODIES WITH A 3rd GENERATION ASSAY

Krupka, Udo; Brust, St.; Julien, Th.
Behringwerke AG, 3550 Marburg, FRG

Objective: To describe the features of a new ELISA (^R^Enzygnost-Anti-HIV 1 + 2) based on synthetic peptides corresponding to env-proteins of HIV 1 and HIV 2.
Methods: 50 µl undiluted specimen are added to 50 µl diluent into each well of microtitration plates coated with a cocktail of 4 synthetic peptides. After an incubation for 30' at 37 °C and 4 washings 100 µl of peroxidase labelled Anti human IgG are added and incubated for another 30' at 37 °C. Colour development was allowed after 4 washings for 30' at RT using TMB.
Results: Of 708 Anti HIV 1-sera and 186 Anti HIV 2-sera all specimens reacted positive, whereby the majority of about 95 % showed O.D. values of greater than 2,0. Compared to 2nd generation assays an improved efficiency was found by clear cut positive results of 12 Anti HIV 1-seroconverters and 5 samples from early stages of HIV 2-infections. By testing 7159 sera from healthy blood donors and 5020 plasma as well as 788 "tricky" specimens an overall specificity of 99,86 % was calculated. No false positive reactivity could be oberserved after heat treatment or freeze-thawing of sera and plasma specimens.
Conclusions: These results and the ease of handling make this new assay most suited for the reliable screening for both Anti HIV 1 and Anti HIV 2.

W.B.P.95 A SEMIAUTOMATED DOT BLOT IMMUNOASSAY FOR THE CONFIRMATION OF HIV SEROPOSITIVITY

Kevin M. Knigge, B. Braun, E. Chan, A. Kapsalis, W. Schulze, J. Stephens, et.al.,
Abbott Laboratories, North Chicago, IL,USA

Objective: To develop an HIV confirmatory assay which is more sensitive and specific than Western Blot.
Methods: Purified recombinant proteins of HIV-1 and HIV-2 are immobilized on nitrocellulose. The assay is conducted in a 35 C incubator automated for timed incubations, sample removal, washing, drying and reflectance reading. A digital print-out records the intensities of the color reactions. The assay requires less than 5 hours to perform and utilizes an alkaline phosphatase detection system. The detection of antibodies to the HIV-1 ENV antigens in addition to either the GAG or POL antigens is used as the criteria for HIV-1 antibody confirmation. The detection of antibodies to the HIV-2 ENV is the criteria for HIV-2 infection diagnosis.
Results: This assay, based on testing of dilution panels, is 8 to 16-fold more sensitive than the current commercially available Western Blot assays for HIV-1 or HIV-2. In a population of 50 AIDS , 50 ARC and 50 asymptomatic seropositive individuals, all were detected by both the dot blot and Western Blot. One hundred percent correlation was found, with Western Blot, on a population of 76 normal blood donors.
Conclusion: This semiautomated dot blot immunoassay offers enhanced performance over the Western Blot with the additional advantage of a non-subjective instrument readout.

W.B.P.92 PREDICTIVE VALUE OF NEOPTERIN, β_2-MICROGLOBULIN AND THYMIDINKINASE IN HIV INFECTION

Göbel, Frank-D., Matuschke, A., Heinrich, B., Püeßl, H.S., Bogner, J.R.: Med. Poliklinik Universität München, FRG

OBJECTIVE: To determine the predictive value of β_2-Microglobulin (β2), Neopterin (Npt) and Thymidinkinase (Tk) in patients (pts) with or without progression of HIV disease.

METHODS: 60 HIV-AB pos. pts in 4 groups with different clinical deterioration within 2 years (group I: progression WR1 to WR 6; II: WR1 to WR3/5; III: WR1 to WR2; IV: WR1 unchanged) were tested for lymphocyte subsets, β2, Npt and Tk
RESULTS: Significant differences between all stages of WR were observed for CD4/8 ratio (ratio) and β2, for Npt only beginning with WR3, for Tk only between WR1 and WR6. Within group IV a significant increase of β2 and decrease of the ratio were seen after 2 years despite unchanged classification in WR1. Comparing WR1 in group I and WR1 in group IV revealed significantly higher values of β2 and Npt, lower values for the ratio in group I.

CONCLUSION: Even in case of stable WR classification changes of β2 and Npt, though unspecific, and ratio are highly predictive and indicate progressive disease. Tk does not seem to have similar prognostic value.

W.B.P.94 The use of the N-terminal portion of the transmembrane proteins for the early detection and discrimination of HIV 1 and HIV 2 infection

VORNHAGEN[1], R.; HINDERER[1], W.; NEBEL-SCHICKEL[1], H.; MOTZ[2], M.; [illegible]-BAUER[2], E.; WALZ[3], A.; WOLF[2], H.; SONNEBORN[1], H.-H.
1 BIOTEST AG, Research Dept., Offenbach, FRG; 2 Max-v.-Pettenkofer Institut, München, FRG; 3 Theodor-Kocher-Institut, Bern, Switzerland

Objective
To determine the usefulness of the transmembrane proteins for early discrimination of HIV 1 and HIV 2 infections.
Methods
A DNA-fragment coding for the N-terminal region of the transmembrane protein of HIV 1 and the corresponding sequence of HIV 2 which has been chemically synthesized were cloned and expressed in E. coli. The recombinant antigens were purified and further evaluated in ELISA-experiments.
Results
Both antigens could be efficiently expressed in E. coli and purified to homogeneity. The purity of antigens were well documented by SDS-PAG-electrophoresis and Western Blot. In ELISA-experiments all sera obtained from HIV 1 and HIV 2 infected persons reacted with one of the recombinant antigens. Although a lot of sera reacted with both antigens a discrimination between HIV 1 and HIV 2 infection was possible.
Conclusion
The transmembrane proteins are very useful antigens for detection and discrimination of HIV 1 and HIV 2 infection.

W.B.P.96 Title : Improvement of anti-HIV-2 reactivity of Vironostika anti-HTLV-III

Authors : E.D. Sprengers, P. Ten Kortenaar, J.A. Hellings,
H.J. Theunissen, J. Ariens and R. v. Sprang, Diagnostics Research
Labs, Organon International B.V., P.O. Box 20,
5340 BH, Oss, The Netherlands

HIV-2 has been described as a second causative agent of AIDS. Therefore anti-HIV-screening assays should be fully sensitive to both anti-HIV-1 and anti-HIV-2 antibodies.
The existing competitive anti-HIV-1 EIA's have a sensitivity of 28-51% for anti-HIV-2 sera; existing indirect EIA's have a sensitivity of 70-93% for anti-HIV-2 sera. Anti-HIV-2 reactivity of anti-HIV-1 EIA's is mainly due to immunologic cross-reactivity of GAG and POL gene products of HIV-1 and HIV-2. We describe a new screening assay, the Vironostika anti-HIV 1+2, with a combination of HIV-1 viral lysate and HIV-2 synthetic peptides as antigen coated to microelisa plates. This combination of antigen results in an increased reactivity with anti-HIV-2 antibodies, without any loss of anti-HIV-1 reactivity. In a preliminary study of 22 anti-HIV-2 sera the sensitivity of the Vironostika anti-HIV 1+2 was 100%, compared to only 36% of the Vironostika anti-HTLV-III, which is based on HIV-1 viral lysate only.

W.B.P.97

"DEVELOPMENT OF TWO DIAGNOSTIC SYSTEMS FOR HIV SEROCONVERSION USING TWO RECOMBINANT ANTIGENS"

Authors:Benítez,J.,Novoa,L.I.,Machado,J.A.,García, J.,Padr'on,G.,Herrera,L.,et al
Center of Genetic Engineering and Biotechnology.
C.Habana,Cuba

Objective:To develope two alternative diagnostic systems for - HIV-antibodies detection using two recombinant antigens.

Methods: The recent development of second-generation tests - - based on simple and manual procedures for rapid diagnosis of HIV antibodies are said to be so reliable and easy to use, they - - could allow future application not only for clinical diagnosis - under elemental laboratory conditions, but also for their use - in the undeveloped countries in order to eliminate the AIDS - - transmission by blood transfusion.
Two systems for HIV1 seroconversion were developed. An indirect sandwich type enzyme immunoassay and a visual test based on a - membrane capture assay with detection of antibodies with a - - protein A-gold conjugated, both using two recombinant antigens - expression products of representative regions of the genes - - coding for the transmembrane 6p-41 and the major core gas 24 - - HIV-I proteins.

W.B.P.98

CROSS REACTON BETWEEN HIV-1 and HIV-2 or DOUBLE INFECTION.

B.L.Schmidt (1,2), F.Gschnait (1,2), F.Mayer (1), J.Hutterer (3), F.Banekowich (3), T.F.Schulz (4), M.Dierich (4). Department of Dermatology of the Hospital of Lainz, Vienna, Austria (1), Ludwig Boltzmann Institute for Dermato-Venerological Serodiagnosis, Vienna, Austria (2), Osterreichische AIDS-Hilfe (3), Institute for Hygiene and Ludwig Boltzmann Institute for AIDS Research, Innsbruck, Austria (4).

HIV-1 and HIV-2 viruses exhibit a high degree of sequence homology, in particular in the core proteins. Antibodies to HIV-2 core proteins might cross-react with HIV-1 and vice versa, whereas envelope proteins are antigenically distinct. Distinction between antibodies to HIV-1 and HIV-2 thus is usually attempted on the basis of reactivity with envelope derived bands of HIV-1 and HIV-2 on Western Blots.

In the present study an ELISA-test system was established using recombinant HIV-2 envelope antigens corresponding to aminoacids (555-761), which derive from or extend into the transmembran proteins. This system recognized 17 out of 18 HIV-2 infected patients (one patient was in terminal disease and did not further produce antibodies). 12 sera, both reactive to HIV-1 (Immunofluorescence and Western Blot) and conventional HIV-2 ELISA (Pasteur), were used for the experiments. 5 of these sera clearly stained the 105 KD envelope band of HIV-2. However, none of them reacted with the recombinant HIV-2 envelope derived antigen.
This study shows that antigenetic cross reactivity between envelope proteins of HIV-1 and HIV-2 does exist and strict care should be taken in interpreting respective results

W.B.P.99

EVALUATION OF HIV-1 AND HIV-2 ELISA BASED ON SYNTHETIC PEPTIDES OF gp41

Kunz, C.*, Heinz, F.X.*, and Parkhede, U.**
*Institute of Virology, University of Vienna, Vienna, Austria,
**Pharmacia Diagnostics AB, Uppsala, Sweden.

Objective. Assessment of peptide-based enzyme-immunoassays for the detection of antibodies against HIV.
Methods. Three different tests were used: an HIV-1 assay based on a peptide from gp41, an HIV-2 assay based on the corresponding peptide from gp36, and a combi-test which contains both the HIV-1 and the HIV-2 peptides.
Results. These tests were evaluated using two panels of sera. Panel A consisted of 200 HIV-1-positive sera which were all confirmed positive by Western blotting. Panel B consisted of 300 sera which had yielded false positive results upon screening in either the Organon ELISA or the Abbott Recombinant ELISA but were Western blot-negative. All truly HIV-positive sera were also recognized as positive in the HIV-1 peptide- and in the combi-test. About 20 percent of the HIV-1 positive sera were also reactive in the HIV-2 peptide ELISA. The absorbance values, however, were always lower than those obtained in the HIV-1 peptide ELISA and rapidly dropped off upon titration. With respect to specificity, the combi-peptide-assay revealed a very low rate of false positive results. Only 16 out of 300 sera that had yielded a false positive result in other HIV assays were also repeatedly positive in the combi-assay.
Conclusion. Due to its specificity and sensitivity the peptide-based ELISA seems to be suited as a routine diagnostic assay.

W.B.P.100

APTITUDE D'UN TEST RAPIDE POUR HIV1 ET DE TESTS D'AGGLUTINATION A DETECTER DES ANTICORPS ANTI-HIV2 AU SENEGAL.

M'Boup, Souleymane*; Sankalé, J.L.*; Kabeya, C.M.**; Diakhaté, L.***; Thiam, D.***, Mitchell, S.****.
*Bactério-Virologie/Université de Dakar, Sénégal, **Projet SIDA/Kinshasa, Zaire, ***Centre National de Transfusion Sanguine/Dakar, Sénégal, ****AIDSTECH/Family Health International, USA.

Objectifs. Evaluer l'efficacité de tests d'immunofixation sur membrane (DOT-Blot) et d'agglutination conçus pour HIV1 au Sénégal, pays où circule à la fois HIV1 et HIV2.
Méthodes. 2000 prélèvements sanguins de donneurs de sang, de personnes à haut risque, et de patients suspects de SIDA ont été testés par HIVCHEK (Dupont, USA). Tous les positifs, les indéterminés, et 10% des négatifs ont été testés en double en RETROCELL (Abott) et en SERODIA-HIV (Fujirebio, Japon). Tous les sérums ont aussi été testés par ELISA en HIV1 et HIV2, puis les positifs par Western-Blot HIV1 et HIV2.
Résultats. Cette étude est en cours et sera achevée en Janvier. La sensibilité et la spécificité des 3 tests pour la détection de HIV2 seront étudiées.
Les résultats provisoires montrent une bonne répétabilité des 3 tests.

Nbre de serums	Hivchek+	Hivchek répété+	Retrocell+ Serodia +	Retrocell Serodia -	Retrocell douteux Serodia +
1005	31	31	27	2	2

Conclusion. Les nouveaux tests de dépistage du HIV qui sont simples, rapides, économiques, et ne nécessitent pas un équipement spécial vont pouvoir faciliter grandement le dépistage dans les pays en voie de développement. Cependant, il est urgent que ces tests comprennent des antigènes multiples.

W.B.P.101

CONTRIBUTION OF SYNTHETIC PEPTIDES (SYP) TO THE SEROLOGIC DIAGNOSIS OF HIV-1 AND HIV-2 REACTIVITY.

Ercilla, Guadalupe, Barrera, J.M., Gil, M.P., Baylo, A., Gatell, J.M. and Castillo, R. Blood Bank and Infectious Med. Dept. Hospital Clinic. Barcelona. Spain.

Objective. To determine the extent of HIV-2 infection in high risk populations and its relationship with HIV-1 infection.
Methods. HIV-1 and HIV-2 antibodies were studied in sera of 215 individuals at risk, 22 out of them showing an indetermined HIV-1 Western Blot, and 70 sera from West Africa people. Sera were screened by ELISA against HIV-1 (Vironostika) and HIV-2 (Elavia-2). The positive results were confirmed by WB HIV-1 (local test) and HIV-2 (Lavoblot-2). A SYP specific for HIV-2 was used in a ELISA test for screening all the sera (HIV-2 Ab Clonatec) and another synthetic peptide was used to confirm seropositivity HIV-2 (Peptilav). The diagnosis of HIV-2 reactivity was demonstrated by the presence of antibodies to the HIV-2 gp 130-105 and reactivity against both HIV-2 SYP.
Results. 40 % of the sera tested had antibodies against HIV-1. 38 % of the HIV-1 positive sera were also reactive by Elavia-2. Four sera were reactive with gp 105 but only three were also reactive with both SYP.
One African's sera was reactive with HIV-2 peptides and gp 105, and failed to react with HIV-1 antigens. None of the WB+undetermined sera were reactive with HIV-2.
Conclusion. Synthetic peptides used as antigens in ELISA method are useful to screen HIV-2 seropositivity. Antibodies against gp 105 allow to distinguish cross reactions between HIV-1 and HIV-2 and Peptilav system is useful to confirm HIV-1 and HIV-2 seropositivity.

W.B.P.102

TYPE SPECIFICITY OF THE HIGHLY IMMUNOREACTIVE EPITOPES OF HIV-1 AND HIV-2

Mirja Korkolainen+, Närvänen, A.+, Kontio, S.+, Rescaldani R.++, Visconti, A. Huhtala, M.-L.
+Labsystems Research Laboratories, Helsigki, Finland; ++Laboratorio Microbiologia, Ospedale Nouvo, Monza, Italy, Department of Clinical Microbiology, Ospedale San Carlo Borromeo, Milano, Italy.

We have developed sensitive EIA's to detect human serum antibodies elicited against HIV-1 and HIV-2. EIA's are based on synthetic peptides derived from transmembrane proteins gp41 and gp34 respectively. These peptides share 30 % homology with each other. In our earlier studies we have compared the HIV-1 specific env peptide EIA to other antibody assays, whole virus EIA's and IB (Närvänen & al.). Now we have tested the sensitivity and specificity of HIV-1 and HIV-2 env peptides by using HIV-1 positive human sera from North-Italy and HIV-2 positive sera from West-Africa. In the case of 100 HIV-1 positive sera all reacted with HIV-1 env peptide, 20 % of them reacted with HIV-2 env peptide. 25 % of HIV-2 positive sera reacted with HIV-1 env peptide. All tested HIV-positive sera were reactive with the mixture of HIV-1 and HIV-2 peptides. In the case of crossreactive sera, it remains open if the reaction is based on sequence homology or are these cases true double infections. In addition, we have tested twenty seroconversion panels from patients infected with HIV-1. Two of these cases can be detected earlier in HIV-1 env peptide EIA than in whole virus EIA, the rest are detected parallel with whole virus EIA (Närvänen & al., J. Med. Virol. 26:111-118, 1988). (Part of this work was conducted with reagents provided through the Global Programme on AIDS of the World Health Organization).

W.B.P.103 EVALUATION OF A NEW COMBINED HIV1&2 IGG EIA BASED ON SYNTHETIC PEPTIDES

Saidl, S.
Blutenspendedienst Hessen, Frankfurt, West Germany

Objective. Recently a new type of retrovirus, HIV2, associated with AIDS was discovered. Although the majority of HIV2 infections are concentrated to West Africa it has also been detected in Europe. Anti-HIV screening might thus in a near future require simultaneous detection of antibodies to HIV1 and HIV2 respectively.
Methods. We have evaluated a new combined HIV1&2 IgG EIA, Pharmacia Diagnostics AB, Sweden. The assay is based on traditional EIA technology utilizing 96 wells microtitration plates coated with synthetic peptides directed towards anti-GP41 (HIV1) and anti-GP36 (HIV2) respectively.
Result. In 5 180 consecutive normal blood donors 10 sera were initial reactive and 8 repeatedly. However, none were Western Blot positive and the specificity estimated to 99.85 %.
In 90 AIDS patients, 89 HIV1-infected and 1 HIV2-infected; all were positives. The absorbance values exceeded 1.000 in 86.
In 88 sera previously yielding repeatedly positive result in EIA:s but all Western Blot negatives 87 were negative.
Conclusion. It can thus be concluded that although addition of the HIV2 peptide the specificity remains high and the cross-reactivity with tricky negative sera are extremely low.
It can also be concluded that the HIV1 signal remains high in the combined test indicating that the sensitivity is not affected.

W.B.P.104 RELIABLE DIFFERENTIATION BETWEEN ANTI HIV-1 AND ANTI HIV-2 ANTIBODIES USING A COMPETETIVE ASSAY

Chr. G. Meyer, D. Bersow, H. Schmitz
BERNHARD-NOCHT-INSTITUT FOR TROPICAL MEDICINE, HAMBURG, F.R.G.

Objective: To clarify the question, if sera, reacting in both HIV-1 and HIV-2 test systems have to be assessed either to Human immunodeficiency virus type I or type II.

Methods: $F(ab)_2$ fragments were prepared from 6 crossreacting sera, purified by gel and affinity chromatography, pooled, and incubated simultaneously with the serum to be examined in antigen coated microtitre plates. After a second incubation step with POD labelled Fc specific anti human IgG the reaction could be visualized.
The 6 sera, from which $F(ab)_2$ fragments were prepared, were reactive in all applied HIV-1 assays and in most of the HIV-2 assays, including immunofluorescence microscopy.

Results: Using this competetive assay, the 6 sera did not react and were found to be HIV-2 nagative.

Conclusion: Blocking crossreactive epitopes on HIV-2 antigen by pooled $F(ab)_2$ fragments prepared from crossreactive sera leads to exclusion of crossreactivity and sera containing antibodies to HIV can be assessed according to their antibody specificity.

W.B.P.105 LINE IMMUNOASSAY FOR THE SIMULTANEOUS DETECTION OF ANTIBODIES TO HIV-1 AND HIV-2 IN HUMAN SERA

Pollet, D.E.*, Saman, Eric*, van der Borght, B.*, Vercauteren, G.**, Buscher, P.**, van der Groen, G.**, et al.
* Innogenetics NV, Antwerp; ** Institute of Tropical Medicine, Antwerp, Belgium

Objective: Evaluation of recombinant proteins and chemically synthesized peptides in a line immunoassay technique (LIA) on their sensitivity and specificity compared to Western blot, for the detection of antibodies to HIV-1 and HIV-2. Methods: In the LIA technique gag (p24 and p17), and pol (endonuclease) recombinant proteins expressed in E. coli, and chemically synthesized HIV-2 env (gp 36) and HIV-1 env (gp 41) peptides were coated as discrete lines onto a nylon strip. Specific antibodies to these antigens in human sera were revealed using an alkaline phosphatase labeled anti-Hu IgG as second antibody. An anti-Hu IgG line was used as a control for the addition of serum. Positive or negative results were determined by visualy comparison of the antigen lines intensity with that of a cut-off line. A panel of 1062 human sera was tested (prevalence 53 % HIV-1, 0.9 % HIV-2) among which 296 of African, 452 of European and 314 of South American origin. All samples were stored frozen. Sensitivity and specificity was compared with western blot (WB) HIV-1 (Dupont) and HIV-2 (ELAVIA Pasteur).

Results

		WB HIV-1 +	WB HIV-1 −
INNO-LIA	+	559	5
HIV-1*	−	8	492

		WB HIV-2 +	WB HIV-2 −
INNO-LIA	+	10	0
HIV-2**	−	0	4

		WB HIV-1 +	WB HIV-1 −
INNO-LIA	+	567	0
HIV-1***	−	0	495

* LIA HIV-1 + = gp41+ or p33+ p24+ p17+ or p33+ p24+ or p33+ p17+, in the absence of HIV-2 gp36. ** LIA HIV-2 + = HIV-2 gp36+ HIV-1 gp41-; LIA HIV-1-2 undetermined: HIV-2 gp36+ HIV-1 gp41+. *** Overnight incubation in LIA of sera with initial doubtful LIA results.
Conclusion: Compared to WB, the LIA technique allows to determine simultaneously HIV-1 and HIV-2 types of antibodies with a sensitivity of 100 % and a specificity of 100 % for HIV-1 and HIV-2, respectively.

W.B.P.106 EFFICACY OF ABBOTT RECOMBINANT HIV-1/HIV-2 EIA FOR EARLY DETECTION OF HIV-2 AND/OR HIV-1 SEROCONVERSION

F. Ferchal, F. Agbalika, P. Honderlick, V. Barateau, Y. Perol,
Laboratoire de bactériologie/virologie, Hôpital St-Louis, Paris, France.

The greatest difficulty in HIV diagnosis in Europe is to have at one's disposal an ELISA test sensitive enough to detect low levels of HIV-2 as well as HIV-1 antibodies. We determined the performance characteristics of Abbott Recombinant HIV-1/HIV-2 EIA by studying sequential sera from one HIV-2 and seven HIV-1 seroconversions.
HIV-2 seroconversion results:

	ELAVIA I*	ELAVIA II*	ELAVIA I + II*	Ab Rec I	Ab Rec I + II	RIPA HIV 2 gp140	p26	p56	p18
June 20, 1988	0.02	0.38	0.38	0.34	0.62	-	-	-	-
June 21	0	0.28	0.28	0.28	0.61	-	-	-	-
June 23	0.42	0	0.85	0.82	1.52	-	-	-	-
July 7	0.20	1.7	1.48	0.77	1.23	+	-	-	+
July 20	0.40	2.9	4.13	0.91	1.33	+	-	++	+
Aug. 11	1.2	≥ 6	≥ 6	0.84	1.97	++	+	+++	++
Aug. 28	2.43	≥ 6	≥ 6	1.04	2.42	++	+	+++	++
Jan. 21, 1989	2	≥ 6	N.D.	1.14	3.42		N. D.		

* Elavia I, Elavia II, Rapid Elavia I and II: Diagnostics Pasteur.

All HIV-2 confirmed positive sera of our panel (n = 21) were detected by Abbott Rec. HIV-1/HIV-2 EIA.
HIV-1 seroconversion results: the seven cases of our panel HIV-1 seroconversions were documented at the same time by Abbott Rec. HIV-1/HIV-2 EIA and Rec. HIV-1 and in five of these cases 13 to 27 days before the Western Blot showed any specific band.
We can conclude that, in our hands, Abbott Rec. HIV-1/HIV-2 recognized all HIV-2 positive sera and low level of initial antibody production associated with HIV-2 or HIV-1 primary infection.

W.B.P.107 DETECTION OF HIV-1 AND HIV-2 ANTIBODIES IN AFRICAN SERA BY THE ENV-9 (gp120-HIV1) RECOMBINANT PROTEIN

Peeters, Martine*; Delaporte, E.*,**; Honoré, C.*; Bedjabaga, L.*; Ossari, S.*; Brun-Vézinet, F.**.
* Centre International de Recherches Médicales, BP 769, Franceville, Gabon;
** Laboratoire de Virologie, Hôpital Bichat/Claude Bernard, Paris, France.

Objective. To evaluate the performance of the ENV-9 recombinant protein in an ELISA test and a rapid test (HIV-check) in detecting antibodies to HIV2.
Methods. A panel of 49 sera, positive for HIV2 antibodies by WB and/or RIPA (presence of gp36 and/or gp140) were tested with the ENV-9 recombinant ELISA (Dupont de Nemours). 20 sera from the same HIV2 panel were tested with the ENV-9 protein in the HIV-check rapid test (Dupont de Nemours). In parallel, a panel of 39 sera, positive for antibodies to HIV1 (presence of gp41/gp120) were also tested for both tests.
Results. All the HIV1 antibody positive sera reacted in the ENV-9 ELISA (OD/cut-off ranged between 3 and 7, median - 5,5) and all these sera were positive in the HIV-check test. Among the HIV2 antibody positive sera 47 of 49 (96%) were positive in the ELISA test (OD/cut-off ranged from 1 to 5, median - 3,5). But only 2 of 20 (10%) HIV2 antibody positive sera reacted in the HIV-check test.
Conclusion. ENV-9 ELISA detects all the HIV1 antibody positive and 96% of HIV2 positive sera. Optical densities were generally lower for HIV2 than for HIV1 sera. The rapid test detects all the HIV1 sera. ENV-9 recombinant protein detects most of the HIV2 sera when it is used in an ELISA, but not in the rapid test.

W.B.P.108 PERFORMANCES OBTENUES AVEC 11 KITS ELISA HIV-1 ET/OU HIV-2 UTILISANT VIRUS ENTIERS, ANTIGENES RECOMBINANTS OU PEPTIDES SYNTHETIQUES ET DES SERUMS AFRICAINS.

Guy Léonard*, G.M.Gershy-Damet**, A.Sangare**, M.Verdier*, S.Ranger*, F.Denis*.
*Département Virologie, CHU Limoges,France.**Institut Pasteur, Côte d'Ivoire.

Objectif : Etude des performances de kits utilisant virus purifié, antigènes recombinants et peptides synthétiques (transmembranaires) HIV-1 et/ou HIV-2.
Matériel et Méthodes : Série de 734 sérums d'Afrique de l'Ouest, étudiés avec les kits : Ortho HIV (HIV-1), Pasteur mixt HIV-1+2(Past), Abbott HIV-1(Abb1), Abbott HIV-1/HIV-2 (Abb12), Clonatec Total (peptides 1+2) (CT), et Typing (peptides 1 ou 2)(C1 et C2), Johnson & Johnson HIV-1 (JJ1) et HIV-2 (JJ2), test Elisa expérimental (peptides 1 ou 2) (Gn1 et Gn2) (Gnann, Science, 1987, 237,1346-1349).
Les sérums positifs avec au moins un des tests ont été soumis simultanément à deux Western Blot HIV-1 et HIV-2 (New Lav blot, Diagnostics Pasteur).
Résultats : Exprimés en terme de sensibilité et de spécificité en respectant les critères des fabricants sauf pour les kits JJ1 et JJ2 (seuil DO=2 et non 0,20 conseillé par le fabricant (spé JJ1 : 54,8% ; JJ2 78,6 %).
Sur les 734 sérums, on compte : 13 HIV-1, 10 HIV-2 et 5 HIV1+2.

	virus entier		Ag recomb.		peptides						
	Ortho	Past	Abb1	Abb12	CT	C1	C2	JJ1	JJ2	Gn1	Gn2
Sensibilité (%)	83.7	100	89.3	100	ND	ND	ND	100	100	88.9	86.7
Spécificité (%)	96.7	91.4	99.2	98.6	ND	ND	ND	99.2	99	98.6	99

Conclusion : Les tests utilisant à la fois des antigènes (viraux ou recombinants) des deux virus HIV-1 et HIV-2 sont plus sensibles, l'utilisation d'antigènes recombinants donnant une meilleure spécificité. Les peptides, très utiles pour le typage, montrent certaines limites pour un dépistage, certains sérums se révélant négatifs, peut-être du fait de l'existence de variants HIV-1 ou HIV-2.

W.B.P.109 SENSITIVITY AND DISCRIMINATORY VALUE OF SYNTHETIC PEPTIDE ASSAYS FOR HIV-1 and 2 INFECTIONS.

Lange, Joep*; Vahlne, A.**; Boucher, C.*; Barin, F.***; Parkhede, U.**** and Goudsmit, J.*. *Academic Medical Centre, University of Amsterdam, Netherlands, **U. of Göteborg, Sweden, ***Lab de Virologie, Tours Cedex, France, ****Pharmacia Diagnostics, Uppsala,Sweden.

Objective. To evaluate a combined HIV-1 and 2 enzyme immunoassay.
Methods. Microtiter plates were coated with: a) a 23 mer synthetic peptide, presenting a continuous epitope of the HIV-1 transmembrane protein (env-1), or b) a 24 mer peptide, presenting a homologous region of the HIV-2 transmembrane protein (env-2), or c) the combination of a and b (env-1/2), or d) the above combination + the entire p24 gag gene product of HIV-1 (p24/env). Samples tested were from 150 Dutch AIDS patients; 60 Dutch homosexual men, taken 1 year after and 30 samples taken at the moment of WB seroconversion; 42 Central African ARC/AIDS patients; 29 HIV-2 infected West-Africans (including one HIV 1/2 double infection).
Results.

Assay:	env-1	env-2	env 1/2	p24/env
Dutch AIDS	150/150	7/150*	150/150	150/150
Dutch 1 yr post s.c.	60/60	8/60*	60/60	60/60
Dutch s.c. at s.c.	29/30	0/30	29/30	30/30
Central African AIDS	41/42	26/42	41/42	42/42
West-Africans	3/29*	29/29	29/29	29/29

* Cross vs. true reactivity evident from OD differences.

Conclusions. Sensitivity and discriminatory value of the synthetic peptide assays for HIV-1 and 2 infections appear excellent. For screening purposes p24 addition may offer a slight advantage.

W.B.P.110 COMPARATIVE PERFORMANCE OF CYCLIC VERSUS LINEAR PEPTIDES IN AN ELISA FOR HIV-1- AND HIV-2-SPECIFIC ANTIBODIES

Lacroix, Martial; Chalifour, R.; Stern, M.D. and Dionne, G.
IAF BioChem International Inc., Laval, Québec, Canada, H7V 1B7

Objective: Report on the superiority of cyclic peptides of the transmembrane glycoproteins over their linear counterparts as antigens in an ELISA for the highly sensitive detection of antibodies to HIV-1 and to HIV-2.
Methods: Peptides covering an immunodominant region of HIV-1 and of HIV-2 transmembrane glycoproteins were synthesized. A fraction of the purified peptides was cyclized under conditions in which the formation of dimers and polymers is minimized. Cyclic peptides were then isolated by HPLC and the absence of residual thiol function confirmed by Ellman's test.
Results: Serially diluted serum samples were prepared from confirmed HIV-1 and from confirmed HIV-2 seropositive patients. Each serum dilution was tested on linear and cyclic peptide-coated microtiter wells. Serum titers measured on cyclic peptide-coated wells were 1.2 to 43 times higher than those obtained on linear peptide-coated wells.
Conclusion: We have found that cyclic peptides mimicking an immunodominant region of HIV are superior antigens than their linear counterparts and that they can form the basis of highly sensitive and specific tests for HIV-antibody detection.

W.B.P.111 A PEPTIDE-BASED MICROTITER ELISA KIT FOR THE DETECTION OF ANTIBODIES TO HIV-1 AND TO HIV-2

Martial Lacroix*, C.L. Penney*, R.J. Dwyer*, M.D. Stern*, F. Bellini*, G. Dionne* and C. Tsoukas**.
*IAF BioChem International Inc., Montreal, Can., H7V 1B7;
**Dept. of Clin. Immunol., Mtl. Gen. Hosp., Montreal, Can.

Although many assays for HIV-1 antibodies are now on the market, they do not always perform as well as claimed by the manufacturers. Clearly, there is an urgent need for a more specific and more sensitive HIV antibody test. Our assay uses synthetic peptides mimicking highly conserved and immunodominant epitopes of gp41 and gp120. It is very sensitive (100%) and very specific (99.8%). Among the 1250 confirmed negatives tested were 250 samples from patients suffering diseases often associated with false-positive ELISA testing (lupus, rheumatoid arthritis, blood fraction recipients, various infectious diseases). Seropositive specimens were obtained from a wide spectrum of risk groups. Our test is more sensitive than WB and is equivalent to RIPA and IFA in detecting early seroconverters. The test also detects HIV-2 antibodies since the peptide cocktail includes one homologous to a region of the HIV-2 gp40 protein. The ELISA is done at room temperature and requires 90 min. to complete.
Conclusion: Our kit is more reliable than others since it has the highest sensitivity and a specificity for both HIV-1 and HIV-2.

W.B.P.112 SEROLOGIC CLASSIFICATION OF US PATIENT SERA DUALLY REACTIVE FOR HIV-1 AND HIV-2

Pau, Chou-Pong*; George, R.*; Wolinsky, S.**; and Schochetman, G.*. *Centers for Disease Control, Atlanta, GA, USA; **Northwestern University Medical School, Chicago, IL, USA.

Objective. To characterize and classify sera of US origin, which are dually reactive for HIV-1 and HIV-2 by EIA.
Methods. Forty-one sera from the Multi-center AIDS Cohort Study that were dually reactive by ELISA were further tested for HIV-1 and HIV-2 antibodies by Western blot (Genetic Systems and DuPont) and by viral peptide assays (derived from the env glycoprotein).
Results. All sera were repeatedly reactive by HIV-1 and HIV-2 ELISA using viral lysate antigens and by DuPont HIV-1 Western blot. Western blot results for the two HIV-2 tests are listed below.

	Positive	Indeterminant	Negative
Genetic Systems	16 (39%)	25 (61%)	0
Biotech/DuPont	0	37 (90%)	4 (10%)

Peptide ELISA for HIV-1 were positive for 38/41 sera (92.7%). Peptide assays for HIV-2 were weakly positive for 2 sera, one of which was also strongly positive for the HIV-1 peptide.
Conclusion. All 41 sera were from individuals infected with HIV-1. Reactions with HIV-2 assays were due to antibodies reacting with epitopes common to the two viruses. Discrepant results between the HIV-2 Western blots were due to differences in antigen preparation and loading.

W.B.P.113 EVALUATION OF HIV-1 AND HIV-2 PEPTIDE ELISA TESTS IN SERA FROM ABIDJAN, COTE D'IVOIRE

Heyward, William*, Rayfield, M.*, Krebs, J.*, De Cock, K.**, Odehouri, K.**, Schochetman, G.*, et al.
*Centers for Disease Control, Atlanta, GA., USA, **Projet RETRO-CI, Abidjan, Cote d'Ivoire.

Objective. To evaluate HIV-1 and HIV-2 peptide ELISA tests in a population with both HIV-1 and HIV-2 infections.
Methods. Sera from 957 persons (hospitalized and non-hospitalized) from Abidjan were tested for HIV-1 and HIV-2 by whole virus lysate ELISA (VEIA), type-specific peptide ELISA (PEIA) against the immunodominant domain of the viral transmembrane protein, and virus-specific Western blots (WB). Using WB-confirmed VEIA-1 and VEIA-2 as standards, the sensitivity (SENS), specificity (SPEC), and positive predictive values (PPV) for PEIA-1 and PEIA-2 were calculated.
Results. By VEIA (WB-confirmed), the overall seropositivity was 19.5%. Thirty-nine (4.1%) were positive for HIV-1 only, and 2(0.002%) HIV-2 only. PEIA and WB testing of 150(15.7%) sera reactive to both VEIA-1 and VEIA-2 showed that an additional 90(9.4%) were HIV-1 only, 19(2.0%) HIV-2 only, and 37(3.9%) remained dually seropositive. Of 150 VEIA dually-reactive sera, 147(98.0%) were WB-confirmed. For PEIA-1: SENS=87.8%, SPEC=96.8%, PPV=92.3%. For PEIA-2: SENS=80.0%, SPEC=98.0%, PPV=80.0%.
Conclusion. In populations with both HIV-1 and HIV-2 infections, peptide ELISA tests are relatively sensitive and specific, helpful in distinguishing HIV-1 from HIV-2, and useful in determining which patients need further evaluation by other laboratory tests such as viral culture or polymerase chain reaction. Dual VEIA reactivity is highly predictive of HIV infection.

W.B.P.114 EVALUATION OF PHARMACIA HIV 1&2 COMBI IGG EIA, A SYNTHETIC PEPTIDE EIA

Grillner, Lena*; Parkhede, U.**; Persson, P O.* and Sandström, E.
*Karolinska Institute, Stockholm, Sweden, **Pharmacia Diagnostics AB, Uppsala, Sweden.

Objective. To evaluate a new anti-HIV EIA, HIV 1&2 Combi IgG (Pharmacia Diagnostics AB). In the test synthetic peptides corresponding to parts of the transmembraneous protein of HIV-1 and HIV-2 are used as antigens.
Methods. 10 402 consecutive blood donations were tested for HIV antibodies by HIV 1&2 Combi, Vironostika anti-HTVL III (Organon Teknika) and Recombinant anti-HIV EIA (Abbott laboratories). Sera from 342 anti-HIV positive patients in differents stages of infection and 9 sera from 7 seroconverters were tested by HIV 1&2 Combi.
Results. The specificity was higher than 99.9 % for all three tests and no statistically significant difference was found between the tests. All 342 anti-HIV positive sera gave a positive result by HIV 1&2 Combi IgG EIA giving a sensitivity of 100 % for this panel. Eight out of 9 sera collected early during seroconversion were positive by HIV 1&2 Combi. Most of these sera had been found negative by the first generation anti-HIV assays.
Conclusion. HIV 1&2 Combi IgG EIA were found to have a high specificity and a sensitivity equal to second generation anti-HIV EIAs. The test is well suited for screening of blood donations and for diagnosis of HIV infection. A great advantage is that the test also detects HIV 2 antibodies.

Techniques nouvelles et améliorées
New and Improved Techniques

W.B.P.115 DETECTION OF HIV-1 ANTIBODIES USING SYNTHETIC PEPTIDES

Mendes, N.; Peixinho, Zulma; Hernandes, H.; Longo, I.; Nakaie, C. and Paiva, A..
Escola Paulista de Medicina, São Paulo, Brazil.

Objective. To standardize an indirect immunoenzymatic assay for the detection of HIV-1 antibodies using synthetic peptides.
Methods. Two synthetic peptides corresponding to a segment of gp41 described by Wang et al. (PNAS 83:6159,1986) and Gnann et al.(Science 237:1346, 1987), respectively with 21 (RILAVERYLKDQQLLGIWGCS) and 12 (LGIWGCSGKLIC) amino acid residues were employed separately in an indirect immunoenzymatic assay (research test kit) for the detection of HIV-1 antibodies, standardized by us. A panel of 318 well characterized positive sera tested by indirect ELISA using whole-virus preparation (VIRGO™ HIV-1 ELISA, Electro-Nucleonics), "Western blot" (Diagnostics Pasteur; Innogenetics) and/or EIA using recombinant viral proteins (Abbott HIV-1 Confirmatory EIA; "Dot blot" and indirect ELISA, Embrabio) was used.
Results. All sera with known HIV-1 antibodies reacted with both peptides except 6 sera from hemophiliac patients that failed to react with the 21 aa peptide and 1 serum from an AIDS patient that did not react with the 12 aa peptide at the regular dilution of 1:50. Negative normal sera and sera presenting false positive reactions in the screening test (Electro--Nucleonics) due to antibodies to H9 cell line proteins, as expected, did not react with the peptides.
Conclusion. Synthetic peptides corresponding to viral proteins epitopes, separately or in combination, are useful for screening and/or confirmation of HIV-1 infection.

W.B.P.116 DETECTION OF ANTI-HIV, CORE AND ENVELOPE IgG, IN HIV-INFECTED AND TROPICAL DISEASED FROM BRAZIL

Timmerman, Arthur, Hammerschlak, N.
Hospital Albert Einstein, Sao Paulo, Brazil

Objective. Anti-HIV assays based on synthetic peptides and recombinant produced antigens have been developed in Europe and US. These tests need, however, also to be documented in countries with other patterns of infections and possibly variations of HIV.
Methods. We have used a test system based on synthetic peptides detecting anti-GP41 from HIV1 and anti-GP36 from HIV2 respectively and recombinant produced P24 (HIV1), Pharmacia Diagnostics AB. They are available as combined tests for screening and single tests for differentiation.
Result. Sera from 87 suspicious HIV-infected patients, original diagnose mainly based on 2 EIA:s, were analyzed. Antibodies to envelope proteins were recognized in 80 and towards core in 76 sera. In five sera neither envelope nor core antibodies were detected by the EIA and when Western Blotted no bands were found. In 38 sera from patients with various tropical diseases, i.e. Paraccocidimycosis, Hansens Dis., Typhoid fever, Schistosomiasis, TB etc., 31 were anti-envelope negatives and 27 anti-core negatives. Five sera were pronounced positives in either envelope (n=3), core (n=1) or both (n=1). In Western Blot 3 were positive and 2 indeterminant.
Conclusion. The synthetic peptides and the recombinant P24 assays opens a possibility to differentiate between core and envelope antibodies and will thus contribute to a reliable diagnosis of HIV-infection also in countries like Brazil with another disease pattern.

W.B.P.117 Comparison of Cambridge Biosciences Recombigen HIV Latex Agglutination Assay with three Commercial ELISA Assays

Authors: M. Tamburini (2), R.G. Downing (2), B. Biryahwaho (1)
(1): Uganda Virus Research Institute, Entebbe - Uganda; (2): WHO/AIDS Control Programme.

Objective: ELISA screening facilities are difficult to maintain in small hospital laboratories. We therefore decided to evaluate a rapid Latex Agglutination Assay for use in Uganda.
Methods: Manufacturers protocols were followed carefully. We gratefully acknowledge the gift of Latex Assay kits by Cambridge Biosciences and the assistance given by Dr. Charles Riggin.
Results: Latex Agglutination Test (LA) was carried out on 100 whole fresh blood samples from Ugandan subjects. After centrifugation, LA was repeated on plasma (PLA). The results were compared with 3 commercially available ELISA Assays namely Virgo (VIR), Wellcozyme (WELL) and Cambridge Recombigen (EIA). Western Blotting (Biorad) (WB) was used as the reference assay. Table below shows sensitivity and specificity for each of the commercial assays tested.

	LA		PLA		EIA		WELL		VIR	
	n	Sens.	n	Sens.	n	Sens.	n	Sens.	n	Sens.
WB POS	45/52	87%	50/52	96%	51/52	98%	51/52	98%	50/51	98%
	n	Spec.	n	Spec.	n	Spec.	n	Spec.	n	Spec.
WB NEG	34/43	79%	41/42	98%	43/43	100%	37/42	88%	37/40	93%

Conclusion: Our preliminary results indicate that this assay would be useful in the Ugandan setting. A further Evaluation in District Hospitals is planned.

W.B.P.118 The determination of additional serological markers concerning HIV-Infection using recombinant viral antigens of all HIV 1 reading frames

VORNHAGEN[1], R.; MOTZ[2], M.; SOUTSCHEK-BAUER[2], E.; PICHLER[3], W.; SIEGL[4], G.; HINDERER[1], W.; WOLF[2], H.; SONNEBORN[1], H.-H.
1 BIOTEST AG, Research Dept., Offenbach, FRG; 2 Max-v.-Pettenkofer Institut, München, FRG; 3 Institute for Clinical Immunology, Bern, Switzerland; 4 Institute for Hygiene and Medical Microbiology, Bern, Switzerland

Objective
The evaluation of additional serological markers for prognostic purposes using recombinant viral antigens of all HIV 1-reading frames.
Methods
DNA-Fragments of all HIV 1-reading frames coding for the major structural antigens and parts of them as well as the in vivo weakly expressed regulative proteins have been cloned and expressed in E. coli. Bacterial lysates of 22 selected clones were further evaluated in Western Blot experiments with a variety of sera from classified infected persons, as well as seroconversions and questionable sera.
Results and Conclusion
The Western Blot experiments demonstrated a large variability in antibody response against the different recombinant antigens. In early clinical stages a strong reaction with the majority of recombinant antigens can be observed while with the progression of the disease the number of recognized antigens is strongly reduced. The only antigens which were detected by all sera were the N-terminal portion of gp41 and the reverse transcriptase (p66).In addition some interesting connections between antibody response and clinical stages could be observed.

W.B.P.119 ANTI-HTLV-I TAX ELISA FOR DETECTION OF INFECTION IN STANDARD HTLV-I ELISA NEGATIVE INTRAVENOUS DRUG USERS (IVDUs).

Glaser,Jordan B*; Poiesz,BJ**; Sliwkowski,M.***; Simpkins,H*; Sninsky,JJ.****; Ehrlich,GD.**; et al.
*Richmond Memorial & Staten Island Hospitals, SI, NY; **SUNY-HSC at Syracuse, NY, ***Triton Biosciences, Alameda, CA, ****Cetus Corp., Emeryville, CA, USA.

Objective: To assess the sensitivity of the standard ELISA for detection of HTLV-I infection.
Methods: Serum was obtained from 235 IVDUs from 5/1/86 to 8/15/87 and tested by HTLV-I ELISA. Since the HTLV-I tax protein product is not packaged in the mature virion, a variety of assays to detect this antigen were prepared to overcome any potential serological window: (i) Radioimmunoprecipitation assay (RIPA), using whole cell lysates from HTLV-I cell lines; (ii) specific tax ELISA and; (iii) specific tax western blots, both prepared from recombinant tax protein. Polymerase chain reaction (PCR) was used to confirm the presence of provirus in all individuals with HTLV-I.
Results: Six of 162 IVDUs had positive standard ELISAs confirmed by both PCR and RIPA and/or standard western blot. Seven of 162 were standard ELISA negative, but PCR, RIPA and tax western blot positive.
Conclusions: Standard ELISA had low sensitivity (6/13; 46%) for detection of HTLV-I. This has major implications with regards to screening blood products and for those studying HTLV-I epidemiology and pathogenesis. Addition of recombinatnt tax protein to HTLV-I viral ELISAs is a viable method to close the detection gap.

W.B.P.120 CLINICAL EVALUATION OF TESTPACK HIV-1/HIV-2 RAPID ASSAY FOR THE DETECTION OF ANTIBODY TO HIV-1 AND HIV-2 USING RECOMBINANT DNA DERIVED HIV-1 and HIV-2 PROTEINS

Alcalde, X.; Weiss, Rachelle; Staller, J.; Prozorovsky, L.; Knigge, K.; Pennington, K.; Abbott Laboratories, North Chicago, IL, USA.

Objective. The Testpack HIV-1/HIV-2 rapid enzyme immunoassay for the detection of antibody to two Human Immunodeficiency Viruses (HIV-1 and HIV-) has been evaluated in clinical trials at four European sites.
Methods. To date, these sites have tested a total of 2455 specimens by both the Testpack HIV-1/HIV-2 assay and the Abbott HIV-1 EIA (Recombinant) assay. These specimens were obtained from random donors, individuals previously determined to be reactive for anti-HIV, individuals previously determined to be reactive for anti-HIV-2, patients with autoimmune disease, patients diagnosed with chronic Hepatitis B, homosexuals and drug addicts.
Results. Data demonstrated an overall specificity of 99% and sensitivity of 100% at the clinical sites. The overall percent Agreement with the Abbott HIV-1 EIA (Recombinant) is 99.1%. This figure includes four specimens that were Testpack HIV-1/HIV-2 reactive and Abbott HIV-1 EIA (Recombinant) negative. These specimens were confirmed by HIV-2 Western Blot. Testpack HIV-1/HIV-2 demonstrated reproducibility both within day and between days.
Conclusion. Clinical studies to date demonstrate good performance of the Abbott Testpack HIV-1/HIV-2 as a rapid assay detection system of antibodies to these two viruses.

W.B.P.121 TESTPACK HIV: RAPID ASSAYS CAPABLE OF DETECTING ANTIBODIES TO HIV PRESENT IN SERUM, PLASMA, AND WHOLE BLOOD

Rachelle A. Weiss, R.M. Pennington, K.M. Knigge, J.M. Staller, L.A. Prozorovsky, A. Martorano, Abbott Laboratories, North Chicago, Il. and Howard Brown Memorial Clinic, Chicago, Il., USA

Objective: To develop rapid, visual immunoassays to detect antibodies to Human Immunodeficiency Viruses 1 and 2. These assays require minimal sample preparation, minimal technical expertise, no sophisticated equipment and provide easily interpretable results.
Methods: These tests utilize full length recombinant antigens p24 and gp41 from HIV-1 either alone or in combination with gp41 from HIV-2. An internal control is incorporated to alert the user to procedural errors. Assays can be completed in 10 minutes, using whole blood, serum or plasma, with results read visually as a plus (+) or minus (-) sign.
Results: Sixty-seven and 132 ELISA positive, Western Blot confirmed HIV-1 samples were tested with the HIV-1 and HIV-1/HIV-2 assays, respectively. Each sample consisted of whole blood and matched serum or plasma. Both assays detected 100% of the samples tested. On a population of 395 normal blood donors, the specificity of these assays ranged from 98% on HIV-1/HIV-2 to 99% on HIV-1. Whole blood, obtained via fingerstick from 115 normal blood donors, was negative in both assays. The presence of the anticoagulants EDTA, heparin and sodium citrate did not interfere with the performance of either assay.
Conclusion: These rapid assays demonstrate high sensitivity and specificity and are appropriate for use in situations which preclude the use of conventional ELISA tests; e.g., stat blood transfusions, emergency rooms, organ transplants, physicians' offices and small laboratories.

W.B.P.122 UNIQUE IMMUNOREACTIVITY OF A NORMAL HUMAN SERUM WITH RECOMBINANT HTLV-I ENV GENE PRODUCTS

Shih, James*; Genesca, J.*; Prenkl, T.**; Terry, R.**; Buonagurio, D.**; Longiaru, M.**; et al. *Dept. Transfusion Medicine, NIH, Bethesda, MD, **Roche Diagnostic System, Nutley, NJ, USA.

Objective: To assess an anti-HTLV-I ELISA test based on recombinant products and to identify the specificity and significance of the immunoreactivity between the serum of a normal blood donor and recombinant HTLV-I envelope proteins.
Methods: Clones containing different regions of HTLV-I genome were constructed and recombinant protein were produced and used as antigen in enzyme linked immunoassay and immunoblotting assays. Sensitivity for the detection of anti-HTLV-I was assessed with a panel of known positive specimens. To assess the specificity and the significance of this immunoreactivity, recombinant proteins of unique or overlapping sequences from different portions of env gene were also produced and used as antigen.
Results: Comparable sensitivity in detection of anti-HTLV-I by recombinant products was observed with a panel of known positive sera in comparison with commercial tests made of viral culture products. A strong and consistent reaction between one normal donor serum with recombinant products was observed. Serum from this donor was not reactive in any currently available commercial anti-HTLV-I EIA tests, Western blot or radioimmunoprecipitation assay.
Conclusions: A specific immunoreactivity between a blood donor serum with a defined region of HTLV-I envelope protein gp21 was identified with recombinant products. This immunoreactivity was unique and its biological significance remained to be assessed.

W.B.P.123 IMPROVED *IN SITU* DETECTION OF HIV NUCLEIC ACID WITH FLUORESCENT PROBES AND LASER EXCITATION.

Hart L, Donovan, Richard M., Bradey PF, Peterson WR, and Goldstein E.
University of California, Davis, California, U.S.A.

Objective - To develop more sensitive instrumentation to detect and quantitate HIV infected cells in culture and in clinical specimens using nonradioactive *in situ* hybridization.
Methods - Acetylaminofluorene (AAF) HIV DNA probes were made and reacted by *in situ* hybridization with HIV infected CEM cell lines. The AAF-labeled probes were detected using rabbit antibodies to AAF, followed by an antirabbit antibody that was labeled with fluorescein. Samples were excited at 488 nm using either a 40 mW argon ion laser, or using a conventional 100 W mercury arc source. The fluorescent emission was detected above 530 nm using a CCD video camera. The percentage of cells stained and their fluorescent staining intensity was quantified using a semiautomated computerized image analysis system and computer programs developed by us.
Results - Comparison of the numbers and intensity of cells stained *in situ* using the laser and mercury source showed that the laser had: 1) a 10 fold improvement in fluorescence signal intensity and 2) improvement in the signal to noise ratio due to lower autofluorescence.
Conclusion - *In situ* detection of HIV nucleic acid using fluorescent probes and an argon ion laser excitation source is more sensitive and has a higher signal to noise ratio than a mercury excitation source.

W.B.P.124 Detection of HIV in Hematopoietic Cells from Patients with AIDS and AIDS-Related Complex (ARC).

Sun, Nora C.J.*; Hsu, M-Y*; Conrad, A.**; Shapshak, P.**; Beall, G.*; and Imagawa D*.
*Harbor-UCLA Medical Center, Torrance, CA, U.S.A. and **Wadsworth V.A. Medical Center, Los Angeles, CA, U.S.A.

Objective. To test the hypothesis that hematologic abnormalities in patients (pts) with ARC and AIDS were related to direct and persistent HIV infection of the hematopoietic precursors in the bone marrows.
Method. We used ^{3}H-labelled cDNA probe and in situ hybridization (ISH) method to detect the presence of HIV nucleic acids in formalin-fixed, paraffin-embedded bone marrow sections from ARC and AIDS (ten in each group) and five non-HIV-infected pts.
Results. Positive cells were found in all ten ARC and eight AIDS pts, but none in two AIDS and five non-infected pts. Most positive cells were mononucleated, resembling lymphocytes and histiocytes. Endothelial cells, interdigitating reticulum cells, erythrocytes, nucleated red cells and immature myeloid cells also labelled with radioactive material in some instances. Positive cells were usually few and far between in each specimen. Megakaryocytes, epithelioid histiocytes, fibroblasts, fibrocytes, osteoblasts, osteoclasts, and osteocytes were consistently negative.
Conclusions. (1) ISH is a useful tool for identification and localization of HIV in tissues. (2) HIV is capable of infecting cells which do not have CD_4 receptors, and may become symbiotic with the host cells and cause latent persistent infection. (3) Hematologic manifestations in ARC and AIDS pts are at least partly caused by direct HIV infection.

W.B.P.125 SEROCONVERSION FOLLOWED BY RECOMBINANT- AND SYNTHETIC PEPTIDE BASED ANTI-HIV ANALYSIS

Lauritzen, Edgar*; Petersen, C.**; Vejlsgaard, G.L.***; Lindhardt, B.Ø.****; Black, F.***** and Horal, P. ******.
*Statens Seruminstitut, Copenhagen, Denmark, **Hvidovre Hospital, Copenhagen, Denmark, ***Bispebjerg Hospital, Copenhagen, Denmark, ****The Fibiger Institute, Copenhagen, Denmark, *****Marselisborg Hospital, Aarhus, Denmark, ****** Sahlgrenska sjukhuset, Göteborg, Sweden

Objective. To define the sensitivity of recombinant- and synthetic peptide based anti-HIV ELISA tests.
Methods. A total of 290 sera, which were collected during the weeks and months of seroconversion, from 75 patients were studied with anti-HIV tests. The 28 patients had acute symptoms, while 47 patients did not report any symptoms connected to seroconversion. For 9 patients the time of exposure was reported. The sera were tested by two different anti-HIV peptide ELISA tests based on synthetic peptides (Pharmacia), recombinant DNA based anti-HIV test (Abbott), and immunoblotting (western blotting) (DuPont).
Results. Second generation anti-HIV analysis with recombinant- and synthetic peptide antigens showed specific antibody detection within 5 weeks from exposure to HIV. - The anti-HIV abs appeared no later than 4 weeks from onset of symptoms, and most often within the first weeks after symptoms. The immunoblotting test and the second generation ELISA tests were positive either simultaneously, or positive test results were only removed one sample from each other.
Conclusion. The serological "window" of acute HIV infection can be reduced by 2-3 weeks by recombinant- and synthetic peptide based anti-HIV assays.

W.B.P.126 HIV-1 POL synthetic peptides

E.D. Sprengers, J.J. Schalken, J.A. Hellings and R. v. Sprang,
Diagnostics Research Labs, Organon International B.V., P.O. BOX 20,
5340 BH, Oss, The Netherlands

The HIV-1 POL amino-acid sequence was analysed for antigenic epitopes by epitope-prediction programmes such as Hopp and Woods. Of the epitopes predicted by this method 14, partially overlapping, peptides were synthesized by solid phase methodology. The peptides were coated to microelisa plates and analysed for reactivity with anti-HIV-1 sera. We identified 3 anti-HIV-1 reactive peptides: AA 230-244 (IKKKDSTKWRKLVDF); AA 945-959 (TKIQNFRVYYRDSRN) and AA 975-994 (AVVIQDNSDIKVVPRRKAKI). The reactivity of these peptides could be increased by conjugation of the peptides to bovine serum albumin. Immunoassays, based on a single of these POL peptides as antigen, however, did not yield 100% sensitivity with P65/51 and P31 western blot positive anti-HIV-1 sera.

W.B.P.127 INVESTIGATION OF RECOMBIGEN$^{(TM)}$HIV EIA (Cambridge BioScience Corporation)

Major, Carol*; McLaughlin, B.*; and O'Shaughnessy, M.V.**
*Ontario Ministry of Health, Toronto, **Federal Centre for AIDS, Ottawa, Ontario, Canada.

Objective. A new, indirect EIA test employing recombinant polypeptides gp41 and 120 (env) and p24 (gag) expressed in *E. coli*, for the detection of antibodies to HIV was investigated.
Methods. A panel of 875 sera was selected to include: 55 seroconversions (134 sera); 89 confirmed reactive sera, including 10 weakly-reactive; 183 indeterminate; 469 unselected routine HIV specimens. Panel sera had been tested by Dupont HIV-EIA in duplicate and immuno (Western) blot (IB) if required.
Results. Recombigen was reactive in 7/55 initial specimens of the seroconversions while IB was indeterminate or nonreactive; but was negative in 1 initial specimen reactiving only with p24 by IB. All reactive specimens from HIV-infected persons were reactive by Recombigen. Ten IB weakly-reactive sera from recipients of HIV-positive Hepatitis B Immune globulin were negative by Recombigen. Of the 183 indeterminate specimens, 6 were Recombigen reactive; 5 of these 6 were subsequently shown to be HIV-infected by culture or subsequent seroconversion, and the remaining 1 is probably a false-positive result. Recombigen produced concordant results with all routine specimens following confirmatory testing.
Conclusion. Based on these data, Recombigen has a sensitivity of 99.7%, specificity of 99.8%, NPV of 99.8% and PPV of 99.7% in the detection of naturally occurring HIV antibodies.

W.B.P.129 EARLY SEROCONVERSION DETECTED BY ANTI-HIV RECOMBINANT ELISA

Samuelson Agneta*, v Sydow M*, Grillner L**, Gaines H***, Forsgren M*, Strannegård Ö*
* Central Microbiological Laboratory of Stockholm County Council ** Dpt of Virology, Karolinska Hospital, Stockholm
*** Dpt of Infectious Diseases, Roslagstull Hospital, Karolinska Institute, Stockholm Sweden

Objective To study the usefulness of the Wellcozyme HIV recombinant test for the diagnosis of HIV infection and, in particular, the ability of the test to detect early seroconversion.
Methods 526 sera comprising a panel including 120 confirmed HIV-positive, 30 Western blot (WB)-negative sera with ambiguous results by other ELISAs and 404 ELISA-negative sera were tested by the Wellcozyme recombinant competitive ELISA. In addition, 18 consecutive sera from 6 patients with primary HIV infection (PHI) with defined onset were studied. Comparisons were made using first generation Wellcozyme anti-HTLV III, Organon Vironostika anti HTLV III, and Abbott Recombinant HIV EIA. Analyses of WB patterns were made using strips from Biotech.
Results No obvious false negative results were obtained, giving a sensitivity of the test of 100%. The specificity was 99.5%; two apparently false positive results were obtained in the group of 30 sera which were WB-negative but gave ambiguous results using other ELISAs. Three sera obtained 4, 6 and 6 days respectively after onset of PHI were negative by Wellcozyme recombinant test as well as all other tests employed. All 15 sera obtained 10 days and onwards were positive by Wellcozyme as well as the Abbott recombinant tests. By contrast only 4 of these sera were positive by the first generation Wellcozyme test, one (obtained 11 days after disease onset) was negative by WB and 6 sera showed detectable antibodies to the p24 antigen only.
Conclusions The Wellcozyme recombinant anti HIV EIA, is a highly sensitive and specific test for the diagnosis of HIV infection. The test is well suited to detect to early seroconversion, being able to demonstrate an antibody response already during the second week of illness during symptomatic PHI.

W.B.P.131 DETECTION OF HIV-1 ANTIBODIES IN IMMUNOMETRIC ELISA BASED ON LABELED SYNTHETIC PEPTIDE

Alexander T. Kozhich*; Vadim S. Ivanov*; Zoya K. Suvorova**
*Shemyakin Institute of Bioorganic Chemistry, Moscow, USSR;
**Central Institute of Epidemiology, Moscow, USSR.

Objective. To compare synthetic-peptide immunometric ELISA and standard ELISA with labeled immunoglobulins.
Methods. Both techniques utilize microtiter plates coated with synthetic peptide. Bound antibodies are detected either by the same but labeled peptide (immunometric format), or labeled anti-immunoglobulins, or protein A. Labeled peptide and anti-immunoglobulins are prepared by attaching biotin.
Results. Assay sensitivity was checked on the panel of 194 Western Blot positive sera from AIDS, ARC and asymptomatic patients. In immunometric assay 76.8 % of sera were positive and in assay with protein A 87.6 % were positive. Sera weakly positive in immunometric assay, gave a positive signal at dilution up to one thousand-fold in assay with labeled anti-immunoglobulins. Immunometric assay detects no IgG, but only IgM. Seventy seven false positive sera by viral ELISA were negative by immunometric assay.
Conclusions. Synthetic-peptide immunometric assay gives lower sensitivity but greater specificity as compared to assay with labeled immunoglobulins and can be used as a confirmatory test.

W.B.P.128 PRODUCTION AND CHARACTERIZATION OF MONOCLONAL ANTIBODIES AGAINST HTLV-I CORE PROTEINS.

Yoshihara, Paul; Williams, S.; Benelli, M.; Majewski, S.; Logan, D. and Goldstein, A.S.. Epitope, Inc., Beaverton, Oregon, USA

Objective. To identify and characterize core protein fragments on HTLV-I Western blot strips utilizing anti-core protein monoclonal antibodies (MAb).
Methods. Balb/c mice were immunized utilizing HTLV-I viral lysate as immunogen. Hybridoma cells were cloned which produced MAb reactive with HTLV-I core protein as analyzed by Western blot and ELISA reactivity utilizing viral lysate and recombinant core product.
Results. Five MAb were produced which were reactive with core protein. Specifically, their reactivity patterns on Western blot analysis were:

Clone	Reactive bands (kilodaltons)
5201	p19,29,33,53
5202	p19,33
5205	p24,42,53
5206	p24
5204	p19,29,33,42,53

MAb were additionally tested against HIV-I core proteins (Western blot) and were found to be non-reactive. All five MAb were shown to be reactive with recombinant core protein by Western blot analysis.
Conclusions. MAb against HTLV-I core protein were produced as demonstrated by reactivity against viral lysate and recombinant core protein. Multiple bands (p19,24,29,33,42,53) were shown to be core-associated by utilizing the MAb on Western blot analysis.

W.B.P.130 DETECTION OF ANTI-TAX ANTIBODY IN HTLV-1 WESTERN BLOTS.

Connelly, Mark; Tadler, M.;O'Connell, C. E.I. Du Pont, Medical Products Department, Wilmington, DE USA.

Objective. To determine whether antibody to the TAX gene product of HTLV-1 may be detected by using viral lysate based western blots (WB).
Methods. HTLV-1 WB strips were obtained from Biotech Research Laboratory and Diagnostics Biotechnology Limited. Samples were incubated as per WB kit instructions. Recombinant p40X (rp40X) or TAX protein, rabbit polyclonal, and mouse monoclonal antibodies to rp40X were produced by Triton Biosciences Inc.
Results. Both the rabbit polyclonal and the mouse monoclonal antibodies to purified rp40X protein reacted strongly to the p36 band in WB strips prepared from virus grown in HUT-102 cells. In contrast, neither antibody reagent reacted with WB strips prepared from virus grown in MT2. Sera from HTLV-1 seropositive individuals were examined for WB reactivity to p36 and rp40X, and for anti-TAX reactivity by RIPA.

	No. p36 (+)	No. p36 (-)
No. RIPA TAX (+)	205	50
No. RIPA TAX (-)	174	118
No. rp40X (+)	157	25
No. rp40X (-)	28	63

	Number rp40X (+)	Number rp40X (-)
RIPA TAX (+)	95	17
RIPA TAX (-)	42	36

Of 972 sera tested by WB alone, 458 (47.1%) were reactive to p36; yet, for 154 sera where anti-TAX antibody was demonstrated independently using RIPA or rp40X reactivity, 141 (91.6%) were WB positive for p36.
Conclusions. The p36 band in WB strips of virus grown in HUT-102 cells shares immunologic crossreactivity with the TAX gene product of HTLV-1. Antibody to TAX may be detected by some, but not all, viral lysate based WB; with the greatest sensitivity achieved through the use of rp40X.

W.B.P.132 VIRONOSTIKA HIV CORE ASSAY : AN ANTI-p24/p55 SPECIFIC TEST USING VIRAL ANTIGEN AND MONOCLONAL ANTIBODIES.

J.J. Schalken, W. Keur, A. Jacobs, P. Vodegel, J.A. Hellings
Organon Int., Diagnostics Res. Labs., Oss, The Netherlands.

Objective: Progression in seropositive individuals to AIDS is strongly associated with declining or absent levels of anti-p24 antibodies, and high levels of antigen. Therefore, it was of interest to develop an assay specific for anti-p24 antibodies.
Methods: Vironostika HIV CORE is based on the inhibition principle using microelisa stripwells coated with a monoclonal anti-p24 antibody, in combination with a fixed amount of HIV/H9 viral lysate, and a monoclonal anti-p24 antibody-HRP conjugate. Antibodies to p24 or p55 present in the sample will inhibit the monoclonal-antigen-monoclonal sandwich.
Results: Performance of the assay with respect to sensitivity and specificity was compared to that of assays based on recombinant proteins, and to that of anti-HIV screening tests. The detection limit of the assay, based on testing dilution series of anti-HIV sera is better than that of current core-specific assays based on recombinant proteins. In seroconversion panels reactivity becomes detectable 2 to 5 bleeds earlier.
Conclusions: The Vironostika HIV CORE micro ELISA assay based on viral antigen in combination with monoclonal anti-p24 antibodies is more sensitive than current tests based on recombinant proteins and can be used to monitor clinical transition from asymptomatic to AIDS and antiviral therapy.

W.B.P.133 A SCREENING ASSAY FOR ANTIBODIES TO HIV-1 USING RECOMBINANT ANTIGENS

Wu, Ping; Keehn, D.R.; Liu, D.J.; Pawlowski, J.M.; Roser, M.A. and Staser, J.A.
Abbott Laboratories, North Chicago, Illinois, USA.

Objective. To develop a screening enzyme immunoassay (EIA) for antibodies to HIV-1 using recombinant antigens which allows detection of both IgG and IgM. This assay is capable of reducing the window between antigenemia and seroconversion.
Methods. The recombinant *gag* (rp24) protein includes the full sequence of p24. The recombinant *env* (rp41) protein includes the full protein sequence of gp41. Human antibodies to HIV-1 are captured on a polystyrene bead coated with purified rp24 and rp41. Captured antibodies are detected colorimetrically using rp24 and rp41 conjugated to HRPO.
Results. The EIA detected all of a population of 40 ARC, 50 AIDS and 65 asymptomatics and 133 randomly selected Western blot positive samples. The recombinant EIA is at least 16 fold more sensitive than a current, viral lysate based, licensed EIA when used to assay serial dilutions of positive samples.
This assay detects anti HIV antibodies earlier than the licensed 1st generation viral assay in 8 of 9 seroconversion panels and in 4 of 9 compared to the Abbott 2nd generation recombinant assay. In all these panels at least one serial sample tested positive both in this assay and the current Abbott EIA for p24 antigen effectively closing the antigenemia/seroconversion window. The profile of anti HIV-1 IgM levels measured in these seroconversion panels suggest that a large part of this early detection is related to anti HIV IgM detection.
Conclusion. The increased sensitivity of this recombinant assay in detecting seroconversion panels is due to a combination of improved IgG sensitivity and IgM detectability. In combination with assay for HIV-1 antigen the window between infection and seroconversion may be substantially narrowed.

W.B.P.134 CHARACTERIZATION OF FULL-LENGTH RECOMBINANT HIV-1 P41 AND P24 FOR USE IN THE IMPROVED ABBOTT HIV-1 ENZYME IMMUNOASSAY.

Rote, Kevin; Holzman, R.; Robey, G.; Braun, B.; Knicker, S. and Severin, J.
Abbott Laboratories, North Chicago, IL, USA.

Objective: Abbott Laboratories has produced a plasmid containing the gene for full length HIV-1 envelope protein p41 in *Bacillus megaterium*. The protein which contains the 45 C-terminal amino acids of gp120 was recovered as inclusion bodies following cell lysis. We have also expressed HIV-1 core antigen p24 in *E. coli*.. The protein p24 (which contains 12 and 44 amino acids of the HIV-1 proteins p17 and p15, respectively) was isolated as an inclusion body using similar procedures. Our objective was the full purification and characterization of these recombinant antigens.
Methods: Purification of p41 was obtained by step elution from hydroxyapatite using sodium phosphate in 0.1% SDS. Purification of p24 was performed by step elution from CM-Sepharose using NaCl following inclusion body solubilization.
Results: Both antigens were determined to be pure by N-terminal sequence analyses and by SDS-PAGE followed by Coomassie and silver stain. Densitometer tracings of Coomassie stained gels indicated purity levels greater than 93% for both antigens. Western blot analyses of purified p24 and p41 demonstrated expected reactivity with monoclonal antibodies against specific regions of the viral antigens and with HIV-1 positive human sera from a variety of geographical areas. In addition, both recombinant proteins competed with their viral counterparts in Western blot assays.
Conclusion: These highly purified antigens contribute to the enhanced sensitivity of the improved Abbott HIV-1 screening assay.

W.B.P.135 DETECTION OF ANTIBODIES TO HIV-1 BY A PASSIVE HEMAGGLUTINATION ASSAY (RETROCELL HIV-1).

Kapsalis, A. ; Wiesner,D.; Krenc,C.; Traylor,D.and Scheffel, Jim
Abbott Laboratories, North Chicago, IL, USA.

Objective: To evaluate the sensitivity and specificity of a simple, passive hemagglutination assay for the detection of antibodies to HIV-1.
Methods: Stabilized human red cells (Duracytes®) are coated with affinity purified p24 and gp41 HIV-1 viral antigens. The assay is initiated by mixing 50 ul of diluted patient serum(1:50 dilution) and 25 ul of the coated duracytes.The agglutination pattern is visually interpreted after a 3 hour incubation at room temperature.
Results: The performance of the Retrocell HIV-1 assay was compared to the Abbott 2nd generation screening test on blood donors from S.Africa, Zimbabwe and Mexico. Specimens which tested initially reactive (IR) by either test were first retested then if found repeat reactive (RR), were confirmed by Western Blot (WB).

	Retrocell		2nd gen screening	
	%IR	%RR	%IR	%RR
S. Africa(n=1471)	1.16*	0.61*	2.05*	1.00*
Zimbabwe (n=2027)	0.25*	0.25*	0.45*	0.15*
Mexico (n=1998)	0.85	0.30	0.25	0.10

*WB positive specimens were removed.

Specimens from 55 AIDS, 33 ARC and 84 asymptomatic patients were all detected by Retrocell; all of these specimens were confirmed by WB with the exception of 2 ARC specimens which tested as indeterminant and negative. The assay also shows equivalent sensitivity to the 2nd generation HIV-1 screening test when tested on serial bleeds from 7 seroconversion panels.
Conclusion: The performance and ease of use of this assay make it appropriate for blood screening in areas of the world where standard EIA procedures are impractical.

W.B.P.136 DETECTION OF IgM AND IgA ANTIBODIES TO HIV-1 AFTER REMOVAL OF IgG BY PROTEIN G.

Weiblen, Barbara.[*]; Schumacher[**], R. and Hoff, R.[*].
[*] Massachusetts Department of Public Health, Center for Disease Control, Boston, Massachusetts, USA; [**] Boston Biomedica, Inc., West Bridgewater, Massachusetts, USA.

Objective. To develop sensitive and specific microassays for IgM and IgA antibodies to HIV-1 utilizing Protein G treatment to remove interfering IgG.
Methods. Twenty-five ul aliquots of plasma were treated with Protein G agarose (Genex) to remove IgG. Removal of IgG was confirmed by ELISA for IgG antibody to HIV-1. Treated samples were tested by indirect ELISA, and the Miniblot immunoblot using IgM or IgA specific reagents. Sixty-two plasma specimens collected serially during seroconversion of 5 individuals were used to evaluate these methods.
Results. Of the 62 specimens, 36 were positive for HIV antibodies by the FDA licensed DuPont immunoblot. IgA antibodies were detected in all 36; IgM antibodies in 26. In 3 individuals where specimens were available for 1-3 months after seroconversion, IgA antibodies persisted longer than IgM. The IgM and IgA antibodies reacted either with envelope alone or with envelope and gag gene products. The indirect IgM and IgA ELISAs were less sensitive and specific than the immunoblot.
Conclusion. IgM and IgA antibodies to HIV-1 are detectable by immunoblot in seroconversion specimens that have been treated with Protein G. Because the newborn's IgM and IgA can be distinguished from the maternal IgG antibodies, these assays may be useful for the diagnosis of congenital HIV infection.

W.B.P.137 STRUCTURAL CHARACTERIZATION OF RECOMBINANT HIV-1 PROTEINS P24 AND P41 BY HPLC PROTEASE V8 MAPPING AND MASS SPECTROMETRY.

Martin, Olivia ; Buko, A. ; Rote, K.; Dorwin, S.; Whatley, H. and Robey, G.
Abbott Laboratories, North Chicago, IL, USA.

Objective: Abbott Laboratories has produced recombinant HIV p24 core protein and envelope protein p41. The recombinant p24 contains the full length sequence of HIV p24 with 12 residues from p17 and 44 residues from p15. The recombinant p41 contains the full length sequence of HIV p41 in addition to the 45 C-terminal amino acids of the external glycoprotein gp120. Our objective was to characterize the primary sequence of these antigens and evaluate reproducibility between production lots.
Methods: Following purification from bacterial cell lysates, antigens were reduced and carboxylated and treated with *Staphylococcus aureus* V8 protease in the presence of urea (p24) or SDS (p41) to obtain peptides. The resulting peptides were isolated by High Performance Liquid Chromatography (HPLC) using conditions optimized for each antigen.
Results: The primary structure of the purified p24 was confirmed by mass spectrometric analyses of the resulting peptides, which corroborated the entire amino acid sequence derived from gene sequencing. Further, a combination of amino acid analysis and time-of-flight mass spectrometry identified the peptides corresponding with the amino- and carboxy-termini. The identity of the amino-terminus was confirmed using an automated liquid phase sequencer. Similar studies are nearing completion for p41.
Conclusion: Besides confirming the expected sequence for our recombinant HIV core and envelope proteins, these data also demonstrate the high degree of reproducibility obtained among multiple production lots of these antigens. This contributes to the enhanced sensitivity of the improved Abbott HIV screening assay.

W.B.P.138 A FILTER IMMUNOPLAQUE ASSAY FOR THE DETECTION AND ENUMERATION OF HUMAN HIV1 ANTIBODY SECRETING CELLS

Vendrell, Jean-Pierre[§*]; Favero, J.[*], Huguet, M.F.[*]; Rabesandratana, H.[**]; Serre, A.[§*]; Cannat, A.[*]
[*] INSERM U65, [**] Laboratoire d'Immunologie, Hôpital Lapeyronie, MONTPELLIER, FRANCE.

OBJECTIVE. To allow the enumeration and the study of the circulating B cells shown to secrete specific HIV1 antibodies in vitro during the whole course of HIV1 infection.
METHODS. PBMC from HIV1 infected and control subjects were incubated on nitrocellulose filters coated with either : HIV1 virus (Diagnostic Pasteur), highly purified gp 160 (S. Rasheed-Los Angeles), or recombinant p24 (Transgene-Strasbourg). Revelation of specific spots was realised by the use of the BCIP-NBT system.
RESULTS. 1) While no spots were evidenced with control PBMC, 1 to $6x10^3$ HIV1 spots/10^6 PBMC and 0,5 to $1x10^3$ "gp 160" or "p24" spots/10^6 PBMC were enumerated with the P[illegible] from HIV1 infected subjects. 2) The results observed with this filter assay [illegible] with seric ELISA and Western blot assays were analogous : thus, for example, HIV1 and "gp 160" spots but no "p25" spots were evidenced in patients with no "p25" Western blot bands.
CONCLUSION. This new technique confirms both our results with the ELISA or Western blot techniques for in vitro antibody production or those of Amadori et al. using a limiting dilution technique. It provides a tool for in vitro studies of cellular B cell regulation in the course of HIV1 infection.

W.B.P.139 CHARACTERIZATION AND CLINICAL SIGNIFICANCE OF HIV p24 ANTIBODY

McRae, Brian*, Thys, R.*, Fico, R.*, Falk, L.* and Allain, J.-P.*
*Abbott Laboratories, N. Chicago, Illinois, USA

Objective. Detect and quantitate p24 antibody (p24 Ab) to monitor natural history and therapy of HIV antigen (HIV Ag) negative individuals.
Methods. Solid phase was coated with recombinant p24 antigen to capture specific antibody. The same antigen labelled with HRPO was used as a probe. Titer and slope of p24 Ab were obtained by plotting the optical density (OD) of 5 dilutions of each sample and extrapolating the intercept at a cutoff of 0.1 OD. These parameters were correlated with HIV Ag level and clinical condition.
Results. A wide range of slopes (y= < 0.1 to > 1.0) reflected the variability of p24 Ab affinity and prevented use of a reference curve for quantitation. The distribution of HIV p24 Ab and Ag in seropositive persons stratified according to clinical condition is shown in the Table. Mean p24 Ab titer was lower in patients with AIDS (432) than ARC (841) or asymptomatic (1637). All but 1 p24 Ab negative sample were HIV Ag positive; in 15.3% of samples, p24 Ag and Ab were both detectable.

Clinical Condition	Number of positive (% of total)				
	p24 Ab titer				p24 Ag
	< 1	1-5	5-500	> 500	
Asymptomatic	12(2.5)	31(7)	212(47)	197(43.5)	21(4.6)
ARC	3(8)	7(19)	18(49)	9(24)	11(29.7)
AIDS	6(8)	24(30)	40(50)	10(12)	35(43.8)

Serial samples from anti-p24 seropositive homosexual males over 2-3 years showed either a stable (48%) or declining (52%) p24 Ab titer. Among patients receiving antiviral therapy, only those treated with alternate AZT-ddC recovered p24 Ab after disappearance of HIV Ag.
Conclusion. Reliable quantitation of p24 antibody provides information on the natural history, the clinical prognosis and the efficacy of anti-viral therapy in HIV infected persons.

W.B.P.140 EVALUATION OF THE WELLCOZYME RECOMBINANT ENZYME IMMUNOASSAY

Cunningham, P.H*; Imrie, A.A*; Cooper, D.A.**
*Centre for Immunology, St. Vincent's Hospital, Sydney, Australia
**The National Health and Medical Research Council Special Unit in AIDS Epidemiology and Clinical Research, The University of New South Wales, Sydney, Australia

Objective: To evaluate the performance of the Wellcozyme HIV 1 Recombinant EIA in a clinical laboratory.
Method: 1621 serum samples collected from patients with AIDS, ARC or Asymptomatic HIV infection and 36 serial serum samples from 3 seroconverting subjects were tested by the Wellcozyme assay; 5 other commercial EIA's were tested on the seroconversion panel and limits of detection were compared.
Results: 1621 out of 1621 samples from known anti-HIV positive patients were correctly identified by the Wellcozyme assay indicating a sensitivity of 100% in this population. There was total agreement between the Recombinant assay, the Wellcozyme Polyclonal assay and the Genetic Systems LAV EIA which had also been used to test these sera. The Recombinant assay detected anti-HIV in 75% of samples collected in the second week following onset of symptoms of primary HIV infection in 3 homosexual males, compared with the next most sensitive assay which detected 25%. In samples collected in the following two weeks the Recombinant assay detected anti-HIV in 100% of sera. Anti-HIV was not detected by any test in sera collected within the first week after onset of symptoms. In a multicentre random blood donor trial conducted by the Australian Red Cross Blood Transfusion Service on 3057 samples, no sample was repeatably reactive by the Recombinant assay, indicating a specificity of 100%.
Conclusion: The Wellcozyme Recombinant assay (based on recombinant envelope and core antigens specifically captured onto microtitre wells by mouse monoclonal antibodies to anti-HIV1) is a sensitive and specific test well suited to a clinical laboratory.

W.B.P.141 HIV-1 SEROPOSITIVE INDIVIDUALS RECOGNIZE DIFFERENT EPITOPES OF P17: POTENTIAL FOR STAGING DISEASE PROGRESSION

Paul H. Naylor*, A.L. Goldstein*, G. Sinnadorai*, P.S. Sarin**, S.S. Wang***. *The George Washington University Medical Center, Washington, DC; **NIH, Bethesda, MD; ***Viral Technologies Inc., Washington, D.C., U.S.A.

Objective. Development of an ELISA method to quantitate the levels of antibody to specific epitopes of HIV p17.
Methods. Synthetic peptides of 15 to 35 amino acids in length, representing the entire HIV p17 protein were synthesized. The presence of antibodies in serum to the peptides was determined using an ELISA procedure. Enhanced reactivity and lower backgrounds were achieved using peptide-BSA conjugates.
Results. Individuals who are seropositive for HIV p17 were found to recognize different epitopes on p17 as defined by the synthetic peptides. The peptide representing the C-terminal appeared to be most immunogenic, while the N-terminal was least immunogenic. Antibodies to the p17 peptide representing the p17 candidate AIDS vaccine epitope (HGP-30) i.e., amino acids 86 to 115, (Naylor et al., PNAS 84, 2951, 1987) were seen by antibodies from a subset (~30%) of seropositive individuals.
Conclusion. Recent observations indicate that a decline in antibodies to p17 may be an earlier serological marker of disease progression than antibodies to p24 (Lange et al., AIDS 1, 155, 1987). These studies with p17 may provide a new diagnostic assay to stage clinical disease progression, and identify of new epitopes for inclusion in an HIV vaccine.

W.B.P.142 DETECTION OF HIV-1 ANTIBODIES IN URINES OF ASYMPTOMATIC AND ARC /AIDS PATIENTS

Gottfried, Toby*, Govindarajan, A.G.*, Kung, J.*, Friedman-Kien, A.**, Cao, Y.**, Urnovitz, H. B.*, et. al. *Calypte Biomedical Company, Berkeley, CA, **New York University Medical Center, NY, NY USA

Objective: We (AFK, YC) have reported detection of antibodies to HIV-1 in the urines of HIV-1 seropositive infected (H+) individuals using FDA licensed tests. In this study, using a recombinant protein dipstick format, we evaluate the detection of antibodies to HIV-1 in the urine of H+ individuals.
Method: Immobilized recombinant HIV-1 envelope protein on a dipstick (Calypte Biomedical Company [CBC] E1 test format) was used to detect antibodies to HIV-1 in unconcentrated urine. The test was carried out at room temperature. Urines tested were random samples collected from 30 H+ individuals (27 asymptomatic and 3 ARC/AIDS patients) and 20 HIV-1 seronegative (H-) individuals. Results were read by 5 different observers as positive or negative by the presence of blue color in a well.
Results: All urines from H+ individuals tested positive (30/30). In contrast, all urines (20/20) from H- individuals tested negative. Positive and negative controls reacted appropriately in all 50 urine samples.
Conclusion: There was a high correlation between reactivity of urines to HIV-1 recombinant envelope protein and serum reactivity in FDA licensed HIV-1 antibody blood tests for both positive (30/30) and negative (20/20) urine samples. These data suggest that urine instead of blood can be used as a sample source for the detection of HIV-1 antibodies. There is a lower risk to health care workers testing for HIV-1 antibodies in urine rather than blood due to 1) substantially lower incidence of infectious HIV-1 virus in urine and 2) eliminating venipuncture and exposure to blood. The CBC dipstick test format used at room temperature adapts to testing in restricted laboratory environments.

W.B.P.143 SIMPLE, EASY TO USE HIV-1 RECOMBINANT ANTIGEN BASED BLOOD ANTIBODY TEST

Urnovitz, Howard B., Mitra, I., Govindarajan, A.G., Weiss, T., Haight, V., Gottfried, T.
Calypte Biomedical Company, Berkeley, CA USA

Objective: Calypte Biomedical Company (CBC) has developed a simple and easy to use dipstick assay for HIV-1 antibodies. In this study, we evaluate the detection of antibodies to HIV-1 in the blood, serum or plasma of HIV-1 seropositive (H+) individuals.
Method: A dipstick format with recombinant HIV-1 envelope and core proteins was used to detect antibodies to HIV-1. Either 200 µls of blood or 100 µls of serum or plasma is added to the first tube containing CBC E1 buffer. The E1 buffer is formulated to reduce background contamination. The dipstick is added, incubated for 30 minutes at ambient temperature, washed, incubated in conjugate and washed. Substrate is added to each of the wells and stopped after 10 minutes. Results are read as presence of color (positive) or no color (negative). Samples were taken from proficiency panels supplied by Massachusetts General Hospital, New York University, Center for Disease Control, Boston Biomedica and San Francisco Bay Area physicians.
Results: The proficiency panels taken together show: 1) the CBC E1 test was more sensitive than FDA licensed HIV-1 antibody test formats, 2) no false positives were observed and 3) there was 100% correlation of all 5 observers with respect to positive and negative responses.
Conclusion: The CBC E1 HIV-1 antibody test is simple and easy to use. We have validated the efficacy of the E1 blocking buffer with respect to false positive samples (originally identified by FDA licensed tests). The test also accurately identified known difficult sample types such as sera that are hemolytic, icteric, lipemic or from patients with rheumatoid factor or systemic lupus erythematosus.

W.B.P.144 PROLIFERATIVE RESPONSE TO SOLUBLE AND MICROPLATE-ADSORBED gp41 SYNTHETIC PEPTIDE IN HIV+ VERSUS NORMAL SUBJECTS

Gabiano, Clara*; Biaiuso, A.*; Palomba, E.*; Pugliese, A.*; Delventhal, H.**; Tovo, P.A.*.
*Istituto di Clinica Pediatrica e *Istituto di Malattie Infettive, Universita' di Torino, Torino, Italy. **Biochrom KG, Berlin, FDR

Objective. To detect specific cell-mediated immunity to a gp41 synthetic peptide, in soluble and adsorbed form, in HIV+ individuals.
Methods. Peripheral blood mononuclear cells obtained from 10 HIV+ subjects (3 AIDS, 7 ARC; 5 adults, 5 children), were incubated in triplicate for 6 days with different concentrations of a gp41 synthetic peptide (5,10,20 µg/ml; BIOCHROM KG,FDR) or in gp41-coated microwell plates and pulsed overnight with ³H thymidine. The effects of PHA (1:100)+gp41 peptide were also assessed. Sixteen healthy HIV- control donors were tested under the same experimental conditions. A stimulation index (≥ 2SD of normal controls) was considered as positive result.
Results. No specific T cell proliferative response was triggered by the soluble form of the peptide. In contrast, the adsorbed form elicited a significant lymphocyte transformation in 5 out of 7 ARC patients (4 adults and 1 child). No response was found in AIDS patients (1 adult and 2 children). Nonetheless, in AIDS subjects a synergistic effect of the adsorbed gp41+PHA on the proliferative response was observed. In all but one control donors no significant gp41-induced lymphocyte proliferation was observed.
Conclusion. Our results indicate that T cell specific immunity to HIV envelope glycoproteins may be evidenced by absorbed synthetic peptide, whereas the soluble form does not elicit any proliferative response. The test we used shows good sensitivity in HIV+ patients. The positive response in one control subject suggests that a cross-reactivity to gp41 structure may occasionally occur in HIV- individuals. The specific T cell deficiency to HIV in AIDS patients may contribute to the unfavorable outcome of infection.

W.B.P.145 DIRECT DETECTION OF HIV-DNA IN PERIPHERAL BLOOD MONONUCLEAR CELLS FROM ASYMPTOMATIC PATIENTS: COMPARISON OF THREE DIFFERENT PROBES.

Castilla, Inmaculada; Bartolomé, J.; Martínez, MG.; Porres, JC. and Carreño, V. Hepatology Unit. Fundación Jiménez Díaz. Madrid, (SPAIN).

Several methods allow the detection of HIV infection, being the nucleic acid hybridization the most useful and sensitivity one. The aim of this study was to directly determine the presence of HIV-DNA in peripheral blood mononuclear cells (PBMC) from anti-HIV positive patients, using 3 different HIV-probes.

A total of 20 asymptomatic seropositive patients (15 IVDA, 2 homosexuals, 1 homosexual drug-abuser, 2 with no risk factors) and 2 AIDS cases (both IVDA) were included. Anti-HIV was confirmed by western-blot and serum HIV p24 antigen (HIVAg) was determined by EIA. HIV-DNA was detected directly in the PBMC by slot-blot hybridization using 3 different probes: a p-pol-cDNA, a full-length cDNA and a full-length RNA-probe. Ten μg of total PBMC DNA were used in each assay.

Serum HIVAg resulted positive in 3/20 (15%) asymptomatic subjects and in the 2 patients with AIDS. HIV-DNA was detected with the p-pol-cDNA-probe in 44% of the symptomless patients, and with the full-length cDNA one, in 50% of them. However, when using the full-length RNA-probe, HIV-DNA was found in 85% (17/20) of the asymptomatic cases, with a statistical difference ($p < 0.05$) between this percentage and those obtained with the other 2 probes. HIV-DNA resulted positive in the 2 AIDS patients with each of the probes. Finally, HIV cultures were performed from 5 of the asymptomatic subjects. Out of them, 4 were HIV-DNA positive and in the other one, HIV-genome was undetectable by the RNA-probe. In all the positive cases, the virus was isolated from the cultures while this did not occur with the negative one.

In conclusion: 1) no differences between the sensitivity of the cDNA-HIV probes have been achieved. 2) The RNA-probe detected more frequently the presence of HIV-DNA than the cDNA ones. 3) HIV-DNA detection is a more rapid method than PBMC cultures for the identification of a current HIV infection.

W.B.P.146 DETECTION OF ANTI-NEF ANTIBODIES IN SERA OF AT RISK INDIVIDUALS.

Verani, Paola*; Titti, F.*; Buttò, S.*; Sernicola, L.*; Rezza, G.**; Lazzarin, A.*** and Rossi, G.B.*.
* Laboratory of Virology, Istituto Superiore di Sanità, Rome, Italy, **Department of Social Medicine, Ministry of Health, Rome, Italy, ***Infectious Disease Clinic, University of Milan, Italy.

Objective. Nef gene seems to down regulate replication of HIV. It is suggested that following infection, antibodies anti-nef would be detected first and would remain the only detectable HIV-specific parameter during the variable period of latency. Moreover in the hypothesis of the association of expression of nef protein with a low level of viral replication, anti-nef antibodies could be a valuable marker to monitor during the progression of infection.
Methods. We have developed an Elisa assay utilizing a recombinant nef protein (provided by L. Montagnier/Transgene). Reactive sera will be confirmed by immunoblot.
Results. We will detect nef antibodies in sera from the following subjects: a) at least 10 seronegative individuals who are heterosexual partners of HIV-1 seropositive subjects; b) at least 20 seroconverters i.v. drug abusers; c) at least 100 seronegative but at risk i.v. drug abusers; d) at least 30 seronegative but highly transfused hemophiliacs; e) serial sera from at least 40 HIV-1 positive i.v. drug abusers who are either not progressing or rapidly progressing into full-blown AIDS.

W.B.P.147 CLINICAL AND THEORETICAL APPLICATIONS OF NEW PROCEDURES FOR HIV RT AND RT ANTIBODY (AB) QUANTITATION.

Gronowitz J. Simon, Neumuller Magnus, Bhikhabhai Rama (1), Kallander Clas F.R., Fenyo Eva Maria (2), Albert Jan (2) et al. Depts of Medical Virology, and (1) of Molecular Biology, Uppsala University, and (2) of Virology, Karolinska Inst, Stockholm, Sweden.

In two accompanying abstracts (   ), we have shown the synthesis and usefulness of a new substrate ^{125}I-Iododeoxyuridine triphosphate for RT analyses, as well as the construction of solid phase coupled templates to achieve further improvements potentiating the direct detection of RT activity in crude specimen. Due to the improved detection sensitivity obtained, analyses have been started to answer the following questions regarding RT and RT ab: 1) what is the sensitivity and specificty of HIV-RT blocking ab? 2) does the anti-HIV ab titer decrease with progressive disease? 3) is there a crossreactivity between HIV1-RT and HIV-RT ab? 4) how efficient are the new procedures for RT activity detection and quantitation, compared to conventional assay, using from virusisolation; pelleted virus, or cellculture supernantant, or crude lymphocyte extracts ? 5) can high RT activity be detected directly, or in pelleted material, from serum or spinal fluid? 6) can RT activity be measured in crude extracts of lymphocytes directly from the infected? 7) does the new assay procedure detect enough RT activity directly in patient specimen in order to determine development of therapy resistant RT? 8) are the solid templates developed, useful for the separation and characterisation of the different RT-forms reported, i.e. the 52 and 66kD proteins.
The present results and conclusions from these studies per the 31st of may 1989 will be given.

W.B.P.148 PASSIVE AGGLUTINATION WITH RECOMBINANT ENV ANTIGEN TO DETECT ANTIBODIES TO HUMAN IMMUNODEFICIENCY VIRUS.

Andrew Proulx, and C. Riggin. Cambridge BioScience Corporation, Worcester, MA, USA.

Objective. To develop a simple and stable test for antibodies to human immunodeficiency virus (HIV-1) which requires no instrumentation and could be used for large scale screening.
Methods. Highly purified recombinant HIV env antigen, CBre3, was adsorbed to blue polystyrene microbeads. A colloidal suspension (0.6% w/v) of the antigen coated microbeads was prepared and tested by passive agglutination (PA) with HIV positive and negative sera. The tests were performed in 96 well microtiter plates by adding 25 ul sample diluent, 1.0 ul sample, and 15 ul latex-antigen to each microtiter well and allowing the latex-antigen and serum mixture to settle and agglutinate 3.0 hours.
Results. A positive reaction gave a diffuse light blue pattern on the bottom of the well. A negative reaction or no agglutination gave an intense blue bead at the bottom of the well. A total of 423 serum samples, 120 positives by EIA and Western blot, 303 negatives were tested blind and retrospectively by PA for antibodies to HIV-1. Sensitivity relative to EIA and Western blot of the passive agglutination technique was 99.2%; specificity relative to EIA and Western blot was 97.7%. Preliminary stability studies indicate that the latex-antigen is stable for several months at room temperature.
Conclusion. These results suggest the test is similar to EIA in sensitivity but more stable upon storage at room temperature.

W.B.P.149 CHEMILUMINESCENT DETECTION OF HIV INFECTED CELLS USING IN-SITU HYBRIDIZATION ASSAY TECHNIQUE

Bronstein, Irena*, Kerschner, J.H.**, Voyta, J.C.* and Jablonski, E.G.**.
*Quest Systems, Inc., Bedford, MA., **Molecular Biosystems, Inc., San Diego, CA, U.S.A.

Recently, we have developed a sensitive chemiluminescent assay for alkaline phosphatase and alkaline phosphatase conjugates based on adamantyl-stabilized dioxetane, AMPPD. (Voyta, J.C. et al, Clin. Chem. 34, 1157 (1988), Bronstein, I., et al, J. Biolum. Chemilum. 2, 186 (1988)). We have applied this chemiluminescent technique to the detection of human immunodeficiency virus, (HIV), in infected cells using in-situ hybridization with photographic detection. HIV-infected and uninfected CEM cells were fixed on slides using 1% paraformaldehyde followed by treatment with 0.2% HCl, at ambient temperature. Hybridization with 10 nM HIV-specific alkaline phosphatase oligonucleotide probes was performed at 55°C followed by a short wash. The slides were developed using AMPPD chemiluminescent substrate and the light signal was detected with Polaroid High Speed instant black and white film. The HIV-infected cells, after a 5 minute incubation, were detected on the film in less than 30 seconds. Comparatively, chromogenic substrate, BCIP/NBT permitted detection of HIV-infected cells in 30 minutes. This novel chemiluminescent readout technology is suitable for simple, rapid and ultrasensitive detection of viral nucleic acid in cells, blots or in solution.

W.B.P.150 INDIRECT IMMUNOFLUORESCENCE TO DETECT ANTI-HIV ANTIBODY

Croxson T Scott*, Shah VJ*, Strand CL*, Polensky H**, Holland PV***, Randell R***, et al. *Beth Israel Medical Center-NYC; **Memorial Blood Center of Minneapolis; ***Sacramento Medical Foundation Blood Center. USA

Objective: An immunofluorescent method [IFA] (Fluorognost-HIV, Thermascan, Inc.) to detect anti-HIV antibody was compared to ELISA and Western blot [WB] (E.I. DuPont) methods.
Method: Samples (n=10454) from 3 blood donation sites and samples from patients (n=1177) with known clinical histories (classified by CDC criteria) were tested by ELISA and IFA. Samples positive in ELISA and/or IFA were confirmed by WB.
Results: For blood bank samples, 37(0.3%) were ELISA reactive, 17(0.2%) were IFA reactive, and 15(0.1%) were WB positive by FDA criteria. Eleven samples were WB indeterminate: RIPA is pending. Based upon samples with definitive WB results, the specificity for ELISA was 99.906% and 99.923% for IFA. For samples linked to clinical history with definitive WB results (n=796), the overall sensitivity of ELISA was 98.816% (98.826% for CDC II/III, 100% for CDC IVA, 96.552% for CDC IVD, and 98.775% for CDC IVC), while the overall sensitivity of IFA was 99.362% (99.061% for CDC II/III, 100% for CDC IVA-IVC). Among CDC II/III and ARC/AIDS patients (n=858), 116 samples reactive in ELISA or IFA were WB indeterminate: 61% were anti-p24 negative, 56% were anti-p31 negative, 26% were anti-gp41 negative, 16% were anti-gp120 negative, 7% were anti-gp160 negative. 84% of anti-p24 negative sampler and 56% of anti-p31 negative samples were from AIDS patients. Among AIDS patients the frequency of positive results in ELISA was 98.3%, in IFA 100%, while in WB (FDA standards) 77.6%; Among well-characterized HIV-infected homosexuals and intravenous drug users in NYC, the frequencies were 97.8% for ELISA and for IFA and 93.0% for WB.
Conclusion: The IFA method employed is sensitive, specific for detecting antibody to HIV, while simple to perform & interpret.

W.B.P.151 SEROLOGIE VIH ET INFECTION A PLASMODIUM FALCIPARUM

CARME Bernard*, [illegible] B.*, GENTILINI M.**, MPELE P.*, [illegible] M.*, YALA F.* et al.

* Centre Hospitalier et Universitaire de Brazzaville, CONGO
** Centre Hospitalo-Universitaire Pitié-Salpêtrière, Paris, FRANCE

OBJECTIF. Compte tenu de la forte fréquence des réactions positives VIH1 Elavia, non vérifiées par les tests de confirmation, observée à Brazzaville où le paludisme à Plasmodium falciparum (Pf) est intensément implanté, il était important de préciser le rôle d'une réactivité croisée possible entre Pf et le VIH.
PATIENTS ET METHODES. - 332 donneurs de sang, agés de 18 à 50 ans, dont 166 HIV+ (Elavia Pasteur: EP) et 166 HIV-, appariés par âge, sexe et jour du don, ont eu, en plus de l'EP, une recherche quantitative de Plasmodium. Un test par Western Blott (WB) a été réalisé pour tous les sujets EP+Pf+ et pour un nombre identique de sujets EP+Pf-, appariés par âge, sexe et valeur de la densité optique (DO). - 30 enfants agés de 3 à 12 ans, sans antécédents notables, présentant un accès palustre (température > 38°5 et parasitémie à Pf > 10.000/mm3), ont eu une sérologie EP.
RESULTATS. - Donneurs de sang. Le taux de Pf+ n'est pas significativement différent pour les groupes EP+ (12.7%) et EP- (9.6%). Le résultat des DO ne montre pas de différences notables qu'il s'agisse de sujets Pf+ ou Pf -. Le taux de confirmation en WB (≈ 60%) est sensiblement le même chez les sujets EP+Pf+ et EP+Pf-. Les réponses incomplètes, fréquentes, en particulier la présence d'une bande p25 et/ou p18 isolée ou associée ne sont pas plus fréquentes pour le groupe Pf+. - Aucun des 30 enfants présentant un accès palustre n'a eu une sérologie EP+.
CONCLUSION. La présence de Pf dans le sang circulant, que les densités parasitaires soient faibles (porteurs asymptomatiques) ou élevées (accès palustres) n'est pas, à l'évidence, une cause à retenir pour expliquer les fausses réactions positives VIH EP à Brazzaville.

W.B.P.152 ELEVATED SERUM LACTATE DEHYDROGENASE (LDH) IN NON-HOSPITALIZED AIDS PATIENTS

Sharpton, Thomas. Kaiser Foundation Hospital, Oakland, Ca. USA

Objective. To evaluate use of LDH in early diagnosis of Pneumocystis carinii Pneumonia(PCP) in non-hospitalized AIDS patients(pts)
Methods. Retrospective review of 20 pts taking zidovudine who had monthly LDH levels as part of routine followup.
Results. Isolated LDH elevations (normal hepatic transaminases and creatine phosphokinase) were found in 12 out of 20 pts, 6 of whom had prior PCP. Four pts developed recurrent PCP treated as outpatients; the LDH was 1571, 1059, 1193 and 1215 IU/l (nl 297-611) at time of diagnosis. All pts had pO_2>70. Eight pts without PCP had elevations of LDH from 1023 to 3030. Three pts had no symptoms, the elevated LDH resolved (1pt) or remained elevated (2 pts); 1 pt had abdominal large cell lymphoma, 1 had disseminated cryptococcal disease; 2 had fever and cough which resolved in 1 week, 1 of these 2 pts had a gallium scan which was normal; 1 pt had disseminated Mycobacterium avian complex. Macrocytosis was common on zidovudine but correlated poorly with LDH. For LDH >1000 the specificity=0.5, positive predictive value=0.33 for diagnosis of PCP
Conclusion. Serum LDH is frequently elevated in AIDS pts on zidovudine, not always associated with an opportunistic infection. The specificity is thus too low to indicate imminent PCP.

W.B.P.153 EVALUATION OF HIV1 ANTIBODY TESTING STRATEGY IN A MIXED LOW RISK/HIGH RISK POPULATION

Jean Downie, R Howard, B.Bowcock and A Cunningham
Virology Unit,ICPMR, Westmead Hospital, Westmead,2145 Australia

Non-specific ELISA screening reactions in low risk persons invariably lead to atypical or indeterminate band profiles on Western Blotting which must be evaluated alongside incomplete Western Blot profiles of true HIV1 positive sera.
METHOD The Westmead HIV1 antibody testing strategy consists of the concurrent use of two screening ELISA kits (Genetic Systems, Wellcozyme or Abbott) followed by supplemental tests including Western Blotting (Dupont), Abbott ENVACORE and antigen ELISA (Abbott) when indicated. Western Blot profiles were classified by guidelines suggested by the Australian National HIV Reference Laboratory:Positive, Negative, and 4 classes of indeterminate patterns.
RESULTS AND CONCLUSIONS Between March 1987-1988, 35,687 sera were tested, 616 of which were repeatedly reactive by both screening ELISAs. Regardless of screening ELISA kit combination, 98% of sera repeatedly reactive by two ELISA screening tests were confirmed positive by both Western Blot and Recombinant ENV ELISA. The remaining 2% were identified as seroconverters. Sera which were discordant on the ELISA screening assays had less than 2% chance of being confirmed positive for HIV antibody or less than 3% chance of being a seroconverter. The incidence of non-specific indeterminate Western Blot profiles was found to be inversely proportional to the specificity of the ELISA screening kits used. The Recombinant Envelope Protein ELISA (ENVACORE) was able to confirm the viral specificity of HIV1 envelope bands (gp160/110,41) on Western Blot. A Western Blot profile which is reactive for HIV1 viral glycoproteins alone or with not more than two other viral proteins (gag or pol) and which is confirmed viral specific by a Recombinant Envelope Protein ELISA can be used as a predictor of seroconversion.

W.B.P.154 SIGNIFICANCE OF AN INDETERMINATE HIV WESTERN BLOT (WBi)

Genesca, Juan*; Shih, J.*; Jett, B.*; Hewlett, I.**; Epstein, J.** and Alter, H.*. * Department of Transfusion Medicine and ** Division of Virology (FDA), NIH, Bethesda, MD, USA.

Objective. To determine the significance of a WBi result in a normal blood donor population at low-risk for HIV infection.
Methods. One hundred donors (D) to 50 recipients (R) were selected from prospective studies of post-transfusional hepatitis. Anti-HIV were tested by EIA (Dupont) and by a licensed WB assay (Biotech/Dupont). A WBi pattern was defined as the detection of any band without meeting the FDA criteria for positivity. We also used a recombinant immunoblot assay (RIBA-HIV216, Chiron/Ortho) with 4 recombinant antigens (p24,31,gp41,120) on an EIA strip, an HIV antigen test (Abbott), an anti-HTLV-I EIA (Dupont) and anti-HIV-2 EIA (Johnson).
Results. Twenty of 100 D were WBi; none were EIA+. p24 was found in 70% of WBi, in 10 cases as a single band. A 6 month post-transfusion sample in 19 R from the 20 WBi D revealed a WBi in 7 (36%); similar to the finding of WBi in 8 of 19 (42%) control R of WB- blood. When 4 serial samples from the 15 WBi R were tested on two occasions, a reproducible WBi was found in only 21 of 60 (35%) samples; a p24 band was reproducible in only 25% of the samples whereas p55 was reproducible in 78%. No R of WBi blood developed a WB+ by FDA criteria or an EIA+. None of the WBi D or R were reactive for HIV antigen and in the RIBA immunoblot assay. Anti-HTLV-I and anti-HIV-2 were - in 5 D R pairs.
Conclusion. 1)A WBi can be found in 20% of a healthy D population anti-HIV- by EIA;2)WBi patterns are poorly reproducible; p24 is the most common band but the least reproducible;3)the recombinant immunoblot is a useful tool for the clarification of WBi;4)D with WBi do not appear to transmit HIV to R; in a low-risk D population is unlikely that a WBi indicates true HIV infection.

W.B.P.155 WESTERN BLOT QUANTITATIF : INTERET DANS LA SURVEILLANCE DES PATIENTS HIV-SEROPOSITIFS

Schiavini D., Puel Jacqueline
Laboratoire de Virologie, CHU Purpan, Toulouse, FRANCE.

Objectifs. Evaluer l'intérêt d'une quantification du Western-blot.
Méthodes. Les bandes d'immunoblot obtenues (Du Pont de Nemours) sont quantifiées par lecture densitométrique automatisée (Electrophoresis Data Centers-Helena). Les résultats sont exprimés en intégrales représentatives de la surface délimitée par chaque pic de la courbe. Deux groupes de 9 patients appariés d'après l'âge, la sexualité et le stade clinique (défini par le CDC) ont été constitués : le groupe Malades (M) formé de sujets ayant progressé du stade II au stade IV, et le groupe Témoin (T) de malades restés asymptomatiques (stades II) durant le même suivi de 24 à 31 mois.
Résultats. Cette technique assure une lecture objective. Elle permet un suivi précis des différents anticorps : ainsi les valeurs représentatives des Ac anti-p24 et anti-p17 sont plus faibles dans le groupe M que dans le groupe T ($p < 0{,}05$) et décroissent jusqu'à s'annuler au cours du suivi ; chez un malade traité par AZT, ces 2 valeurs augmentent alors que l'antigénémie p24 disparait. Sa sensibilité est supérieure à celle des tests EIA de 2ème génération (ENVACOR Abbott) pour la détection des anticorps anti-p24. Sa reproductibilité intrasérie est bonne. Cependant elle pose des problèmes méthodologiques (défaut de reproductibilité intersérie) nécessitant l'apport d'améliorations.
Conclusion. Les perspectives sont intéressantes dans l'évaluation précoce de l'évolutivité de la maladie chez les sujets asymptomatiques, dans le suivi des nouveaux-nés de mères séropositives et dans la surveillance du traitement antiviral.

W.B.P.156 FIELD EVALUATION FOR THE DETECTION OF HIV-1 SPECIFIC IGG ANTIBODIES (HIV-AB) IN SALIVA: A COST-EFFECTIVE AND ACCURATE ALTERNATIVE TO BLOOD TESTING

Behets, Frieda*; Edidi, B.*; Atikala, L.*; Quinn, T.C.**; Brown, C.*. *Project SIDA, Kinshasa, Zaire; **NIAID, NIH, Bethesda, Maryland,U.S.A.

Objective. To determine the sensitivity and specificity for the detection of HIV-1 antibody in saliva using commercial ELISA and Western blot assays in a high risk population.
Methods. Saliva and serum samples were concurrently collected from 387 prostitutes and their 71 male clients in Kinshasa. Both serum and saliva were tested by ELISA (Organon) and repeatedly reactive samples were tested by Western blot (DuPont).
Results. 134 (34.6%) of the 387 prostitutes and 11 (15.5%) of 71 male clients were HIV-1 seropositive as determined by ELISA and Western blot results of serum. Of these 145 seropositive individuals, 137 (94.5%) were positive by saliva ELISA and Western blot. Of the 8 false negative saliva samples, 5 were ELISA positive but Western blot indeterminate on saliva testing. Of 313 seronegative individuals, none were positive on saliva testing. Of 7 women who seroconverted over a 3 month period, 2 had saliva that was ELISA positive and Western blot positive, while 2 had saliva that was ELISA positive, Western blot indeterminate.
Conclusion. In this field evaluation of testing saliva samples for the presence of HIV-1 antibodies, saliva testing had a sensitivity of 94.5% and a specificity of 100% compared to serum ELISA and Western blot testing. However, if individuals with ELISA positive, Western blot indeterminate saliva results subsequently undergo serum testing, the sensitivity of the screening method increases to 97.9%. Saliva testing for HIV antibodies represents an economical alternative method for screening patients when invasive techniques such as venipuncture are not possible.

W.B.P.157 APPLICATION OF VIRUS CULTURE AND PCR FOR HIV DETECTION IN BLOOD DONORS WITH PERSISTENT ANTI-P24 REACTIVITY IN WESTERN BLOT

Van Der Poel, Cees*; Wester, M.**; Reesink, H.*; Termette, M.**; Bruisten, S.**; Huisman, J.**
* Red Cross Blood Bank, Amsterdam, ** Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, Amsterdam, The Netherlands.

Objective. To investigate the presence of HIV in blooddonors with persistent indeterminate anti-p24 reactivity in HIV Western Blot.
Methods. PBL from 11 blood donors with persistent anti-p24 in HIV WB, previously described as non infective to recipients of blood (Lancet 1986;ii:752-753) and HIV positive cells were co-cultivated with PHA stimulated PBL from HIV negative donors, and cultured for >30 days. HIV expression was monitored by RT and p24 capture assay. After culturing HMW-DNA was isolated and applied in PCR. The PCR was performed with 2 primer sets for pol and gag. Putative amplificates were confirmed on Southern Blot using internal oligonucleotides of 40 bp specific for pol and gag respectively, radio labeled with ^{32}P.
Results. None of 11 donors with persistent anti-p24 reactivity in WB were found positive in culture. The results of PCR analysis will be presented.
Conclusions. Will be discussed.

W.B.P.158 ANTI-NEF ANTIBODIES IN BLOODDONORS WITH PERSISTENT ANTI-P24 REACTIVITY IN HIV WESTERN BLOT, AND CHARACTERIZATION WITH RECOMBINANT P24 IN BIDIMENSIONAL BLOT AND ELISA.

Van Der Poel, Cees*; Gadelle, S.**; Reesink, H.*
* Red Cross Blood Bank, Amsterdam, The Netherlands ** Diagnostics Pasteur, Marnes-la Coquette, France.

Objective. To investigate the presence of anti-NEF antibodies as a marker of HIV infection in blooddonors with indeterminate anti-p24 HIV Western Blot reactions, and to further characterise this reactivity employing recombinant p24 as antigen.
Methods. Serum samples of 11 blooddonors with persistent isolated anti-p24 reactivity in HIV Western Blot, previously described as being non-infective for HIV to recipients of blood, (Lancet 1986;ii:752-753) were tested for anti-NEF antibodies, employing recombinant NEF protein (Transgene, Diagnostics Pasteur) in ELISA and WB. The serum samples were further tested in bidimensional blot and ELISA with recombinant p24 protein (Transgene, Diagnostics Pasteur), obtained native from E. coli, as antigen. Bidimensional blotting was performed by electrophoresis according to electric charge in a pH gradient and in second dimension by molecular weight with SDS-PAGE, and afterwards transferred to a nitrocellulose membrane.
Results. In recombinant p24 ELISA 5/11 sera were repeatedly positive and 1/11 was borderline positive. In bidimensional blot 3/5 sera were positive, and 1/5 gave an indeterminate reactivity. Results of anti-NEF testing will be presented.
Conclusions. Will be discussed.

W.B.P.159 DETECTION OF HIV-1 SPECIFIC ANTIBODIES AND NEUTRALIZING ACTIVITY (NT Act.) IN THE URINE OF SEROPOSITIVE PERSONS.

Cao, Yunzhen*; Mirabile, M.*; Li, X.L.**; Ho, D.D.**; Dietrich, D.*; & Friedman-Kien, A.E.*. *New York University Med. Center, NY, NY; **UCLA School of Medicine, Cedars-Sinai Med. Center, Los Angeles, CA. U.S.A.

Objective. To detect antibodies to HIV-1, including neutralizing antibodies in urine samples from 56 HIV-1 seropositive individuals.
Methods. Fifty-six persons including 17 patients with AIDS-KS, 16 with AIDS-OI, 8 with ARC and 15 asymptomatic seropositive homosexual men were tested for HIV-1 specific antibodies in both serum and urine (concentrated 100-200X) by ELISA, Western blot (WB), and RIPA. HIV-1 NT act. was determined using a neutralization assay performed with the H9 clone as target cells and HTLV-IIIB as the virus inoculum.
Results.

Samples Tested	ELISA	No. reactive (%) by WB p24	gp41	gp120	gp160	No. reactive (%) by RIPA p24	gp41	gp120	gp160	NT act.
Serum	56 (100.0)	45 (80.4)	54 (96.4)	54 (96.4)	56 (100.0)	35/46 (76.6)	41/46 (89.1)	44/46 (95.7)	46/46 (100.0)	23 (41.1)
Urine	55 (98.2)	35 (62.5)	41 (73.2)	55 (98.2)	56 (100.0)	30/46 (65.9)	29/46 (65.2)	32/46 (69.6)	44/46 (95.7)	19 (33.9)

The titers of the HIV-1 antibodies and HIV-1 NT act. found in the urine corresponded to the titers of the antibodies to HIV-1 and NT act. in the serum.
Conclusion. 1) Specific antibodies to HIV-1 were detected in urine of HIV-1 seropositive individuals. 2) HIV-1 NT act. was shown in 200X concentrated urine from those who were HIV-1 antibody positive in both serum and urine. 3) The anti-HIV-1 antibodies in the urine may be derived from the serum.

W.B.P.160 COMPARISON OF WESTERN BLOT (WB) INTERPRETIVE CRITERIA FOR HIV-1 ANTIBODY

Schable, Charles; George, J.; Phillips, S.; and Schochetman, G.
Centers for Disease Control, Atlanta, GA, USA.

Objective. To compare the four main proposed WB interpretations for their ability to confirm HIV-1 infection.
Methods. Proposed criteria include: I) Assoc State Terr Public Health Lab Directors (ASTPHLD), II) Consortium Retro Serol Stand (CRSS), III) American Red Cross (RC), IV) Dupont-FDA licensed WB kit. We evaluated each criteria by testing sera from 436 randomly selected patients as follows: AIDS (n=86), ARC (n=40), EIA repeatedly reactive (RR) asymptomatic homosexual men (n=58), and EIA negative volunteer blood donors (n=250). Each serum was tested by the FDA licensed Dupont Western blot kit and the results were scored as positive (P), negative (N) or indeterminate (I) according to the four definitions.
Results. The data presented indicate that the ASTPHLD criteria were the most sensitive and specific of the four criteria examined.

	ASTPHLD P(%)	I(%)	CRSS P(%)	I(%)	RC P(%)	I(%)	DP P(%)	I(%)
AIDS	83(96)	3(4)	76(88)	10(12)	74(86)	12(14)	62(72)	24(28)
ARC	39(97)	1(3)	38(95)	2 (5)	36(90)	4(10)	34(85)	6(15)
RR MEN	45(78)	13(12)	43(74)	15(26)	41(71)	17(29)	39(67)	19(23)

The most restrictive criteria (requiring the presence of GAG, POL and ENV), RC and Dupont, yielded higher numbers of indeterminates, usually due to a lack of GAG/POL antibody in AIDS patients.
Conclusion. The ASTPHLD criteria have the least number of indeterminates in all categories. This allows more accurate interpretations while minimizing indeterminate results which must be followed by further serologic examinations. We would, however, alter the negative statement from no viral specific bands present to no bands present.

W.B.P.161 The Use of Recombinant HIV ELISA Kits as a Secondary Supplemental Test for Confirmation of HIV Infection

D. Lepine, S. Frenette, M.V. O'Shaughnessy, Federal Centre for AIDS, Ottawa, Ontario, CANADA

Improvements in the sensitivity and specificity of HIV EIA kits and in the performance of supplemental confirmatory tests have made the serological diagnosis of HIV infection far more reliable in recent years.

We initiated a study involving over 3000 sera to evaluate the performance of a Recombinant HIV ELISA Ab kit from Cambridge Bioscience (CBC). The kit employs 96 well microtitre plates coated with recombinant proteins from the gag and env gene products of HIV. In an initial analysis, 333 blot indeterminate, 862 blot positive and 521 blot negative samples were retested using the CBC test. The samples were unselected in that all sera submitted for reference analyses were tested by the CBC procedure. All immunoblot positive sera were positive by CBC while 23 of the 333 blot indeterminants were positive using this recombinant test. One of the 521 blot negative samples was positive by the CBC test and could represent a false positive result. This preliminary evaluation indicates recombinant protein-based kits may be extremely useful adjuncts in HIV testing especially when used as supplemental tests.

W.B.P.162 LABORATORY IDENTIFICATION OF RECENT HIV SEROCONVERSION: THE UTILITY OF EARLY REPEAT SPECIMENS AND COORDINATION WITH THE COUNSELING TEAM.

Judith C. Wilber*, B Louie*, E Soncuya*, A Back*, A Brickman**, A Lifson* et al. *San Francisco Dept of Public Health, **University of California AIDS Health Project, San Francisco, CA, USA.

Objective. To study the collection of followup specimens when there are apparent indeterminate results in a high risk population. The objective was to determine serologic patterns consistant with early seroconversion, minimize time of uncertainty for clients with indeterminate results, and communicate these findings to the counseling and education teams.
Methods. Low level of antibody was defined as 1) EIA ratio >0.8 and <2.5, 2) immunofluorescence (IFA) titer ≤1:10, and 3) 1-3 viral bands on Western blot (WB). A second specimen was obtained 2-4 wk later (median 14 d, mean 15.9 d) by requesting a new blood draw at the time of the results reporting and counseling. It was possible to maintain anonymity and the link between the 2 specimens by including the previous specimen number on the new lab slip.
Results. Of 54,000 specimens tested 1985-1988, 52 were defined as low positive. In 29 of 30 cases where a second specimen was obtained, the EIA absorbance, the IFA titer, and the number of bands on WB increased, suggesting that these were early seroconversions. The WB patterns commonly consisted of p24 and very weak gp160 on the 1st specimen; the second specimen showing gp120 and other gag and pol bands.
Conclusions. Certain serologic responses may be indicative of early seroconversion, which can be confirmed on followup specimens taken 2-4 weeks later. Identification of such recent seroconverters may be valuable for planning and evaluation of prevention and education efforts.

W.B.P.163 THE D-MANNOSE-SPECIFIC LECTIN FROM GERARDIA SAVAGLIA BLOCKS BINDING OF HIV-1 TO H9 CELLS IN VITRO.

Müller, Werner E.G.; Reuter, P.; Renneisen, K.; Schröder, H.C.
Institut für Physiologische Chemie, Universität, Duesberweg 6, 6500 Mainz, West Germany.

Objective. To describe that lectins can be used as a tool to inhibit HIV infection in vitro. Methods. Human T cells (H9), infected with HIV-1 have ben used for the studies. Results. The new (alpha-1-->2)D-mannose specific lectin from Gerardia savaglia is shown to prevent infection of H9 cells with HIV-1 in vitro. At 0.2 µM a complete protection was achieved. Moreover, the lectin inhibits syncytia formation in the HIV-1/H9-Jurkat cell system to 100 % at 0.2 µM. This effect was abolished by coaddition of D-mannose at a stoichiometric ratio of lectin to sugar of 1:500. In addition it is shown that the lectin reacts with the oligosaccharide side chains of HIV-1 gp120 env molecule; after deglycosylation of the gp120, the resulting 58-60 kDa form did not react with the lectin. Conclusion. This new lectin allows the development of assays (i) to screen for compounds that interfere with the gp120-CD4 interaction and (ii) to detect viral antigens in patients' sera. Refs.: Kljajic et al., Europ. J. Biochem. 169, 97 (1987); Müller et al., J. Acquired Immune Def. Syndr. (1989), in press. Supported by grants from the Bundesgesundheitsamt.

W.B.P.164 EARLY SEROLOGIC EVIDENCE OF INFECTION WITH HUMAN IMMUNODEFICIENCY VIRUS-TYPE 1 (HIV-1)

Phair, John, Crisler, J., Huprikar, J., Tsung, L. Hart, D. and Chmiel, J.
Northwestern University Medical School and Howard Brown Memorial Clinic, Chicago, Illinois,U.S.A.

Objective: To determine the prevalence and significance of indeterminant western blot (WB) assays in homosexual men with negative Enzyme-Immunoabsorbent Assays (EIA).
Method: The Chicago component of the MACS followed 396 EIA-negative men from 1984-85 through 10/1988. At 6 mo. intervals an EIA was obtained; WB were performed at 2 or more visits.
Results: By 10/88, 60 of the 396 had developed a WB confirmed EIA; 24 had bands to 1 or more products of the GAG, POL or ENV gene regions 6 mo. or more before the visit with the diagnostic WB confirmed EIA. In contrast, 15 of 336 who remained EIA negative through 10/88 had similar indeterminant WB at 2 or more visits ($X^2 = 72$, $p<0.0001$). Of the 15, 7 had 2 bands on at least 1 visit. The mean CD4 cell count of these 15 was 906/mm^3 (493-2012) at entry and 864/mm^3 (435-1427) at the 9th visit.
Conclusion: Of 39 homosexual men with negative EIA and an indeterminant WB, 24 developed a WB confirmed EIA (positive predictive value 61.5%). In contrast 321 of 357 with persistently negative WB remained EIA-negative during the 48 mo. study period (negative predictive value 89.9%). Individuals at risk, with indeterminant WB should be closely monitored for definitive evidence of HIV-1 infection.

W.B.P.165 IS THERE A LONG 'SILENT' PERIOD BEFORE ANTI-HIV-1 SERUM ANTIBODIES APPEARANCE IN HIV-1 INFECTION?

Pineda, Juan A; Leal, M; Aguado, I; Rey, C; Torres, Y; Lissen, E.
University of Seville. Seville. SPAIN.

Ranki et al.[1] have suggested that a period as long as 14 months can pass since HIV-1 infection is acquired to Anti-HIV-1 serum antibodies appearance, if a non-recombinant, type 'sandwich' EIA (sEIA) is used to test them. However, if a recombinant, competitive EIA (cEIA) or a Western-Blot analysis (WB) are employed, antibodies to the HIV-1 core proteins are able to be detected during this 'silent' period.
Objective: To gain more knowledge on the HIV-1 serology during this period of HIV-1 infection.
Methods: We have studied serum samples sequentially taken from 17 subjects (4 homosexual men, 5 hemophiliacs, 7 intravenous drug abusers and the spouse of an infected man) who seroconverted for Anti-HIV-1. Three of these patients suffered from an acute, self-limited, febrile illness. The samples were collected between 14 and 1 months before they developed Anti-HIV-1. Seroconversion (SC) was defined as the appearance of Anti-HIV-1 antibodies tested by a recombinant sEIA in a sample taken from a subject who previously had been proved to be seronegative.
Results: All of the samples collected before SC were found to be negative for Anti-HIV-1 when tested by both cEIA and WB. Two patients were Anti-HIV-1 positive earlier when tested by recombinant sEIA than when a non-recombinant sEIA was used. Four of the 17 subjects turned out to be positive for HIV-1 Ag in serum before SC.
Consclusion: These results show that there is not a long 'silent' period before SC for Anti-HIV-1 if a highly sensitive EIA is used to test this marker. Moreover, this seems to be in the same way regardless the risk group and the clinical picture of acute HIV-1 infection.

Ranki et al. Long latency precedes overt seroconversion in sexually transmitted human immunodeficiency virus infection. Lancet 1987; 2: 589-59[illegible].

W.B.P.166 COMPARISON OF FALSE POSITIVE REACTIONS IN DIRECT BINDING ANTI-HIV ELISA USING CELL LYSATE OR RECOMBINANT ANTIGENS

Craske John,* Abbott R,* Collier M,* Mortlew V,+ Love E,+ and Lee D,+
National Blood Transfusion Service,+ Manchester and Lancaster, Public Health Laboratory, Manchester,* U.K.

Objective Comparison of prevalence of false positive reactions in a commercial anti-HIV ELISA in blood donors using antigen from H9 infected cell lysates with those in the same assay using recombinant antigen.
Method In 1987-88 a commercial anti-HIV ELISA test using antigen from infected H9 cells was used to screen blood donors in the Manchester and Lancaster blood banks. In April 1988 an ELISA using recombinant antigen from the same company was introduced. Reactions not due to anti-HIV-1 on confirmatory testing and follow-up for 1 year were analysed by Western Blot.
Results False positive reactions were found at a prevalence of 1/800 (0.2%) in 1987-88. Study of 60 of these donors showed 57 reactive by Western Blot; 7 had anti-p24 ± 55 bands and 50 anti-p18 ± 55 bands. From April 1988 the recombinant assay had a higher prevalence (0.5%) of reactive samples. Most were negative in 3 other immunoassays, and by Western Blot:- 12 were positive by the Abbott recombinant test only; 9 had anti-p18 ± p55 on Western Blot and 3 had anti-gp120/60, one with gp41. Eleven donors positive on screening in 1987-88, reactive by Western Blot, were negative by the recombinant anti-HIV ELISA when referred after April 1988. Further studies continue.
Conclusion False positive reactions in the recombinant ELISA recognises different epitopes to those recognised by the anti-HIV ELISA using antigen from HIV infected cells.

W.B.P.167 NEGATIVE RESULTS OF IN VITRO TESTS FOR HIV1 ANTIBODY PRODUCTION BY PERIPHERAL BLOOD CELLS IN 12 CASES OF ISOLATED GAG-ENCODED PROTEIN POSITIVITY.

Ducos, Jacques**; Vendrell, J.P.**, Reynes, J.***, Huguet, M.F.*, Cannat, A.*, Serre, A.**.
* INSERM U65, ** Laboratoire d'Immunologie, Hôpital Lapeyronie, *** Service Maladies Infectieuses, Hôpital St Eloi, MONTPELLIER, FRANCE.

OBJECTIVE. To provide a help for the interpretation of ambiguous results observed in the course of systematic surveys : weak HIV1 seropositivity of ELISA tests, together with isolated bands of p25 (or other gag-encoded/protein) bands with no gp bands probably correspond to HIV1 "false positivity" and not to a very early stage of HIV1 seroconversion. The interpretation of such tests is however difficult and stressing.
METHODS. PBMC from 12 cases of isolated gag-encoded protein positivity and from 12 cases of classical asymptomatic HIV1 seropositivity were incubated : a) in the wells of Pasteur ELISA kits : the in vitro secreted HIV1 antibodies were revealed by the use of an amplifying immunoenzymatic complex, b) in antigen-free plates : the supernatants were then used for Western blot analysis on strips from the Pasteur kit, thus allowing a comparison of seric and supernatant Western blot profiles.
RESULTS. HIV1 in vitro ELISA and supernatant Western blot tests, positive in all HIV1 infected subjects even at very early stages of sero conversion were constantly and repeatedly negative in the 12 cases of isolated gag-encoded positivity.
CONCLUSION. Since circulating B cells have been shown to secrete HIV1 antibodies in vitro during the whole course of HIV1 infection, the absence of such cells should help to eliminate the diagnosis of HIV1 infection in these ambiguous cases.

W.B.P.168 COMPARISON OF INDIRECT IMMUNOFLUORESCENCE AND WESTERN BLOT-TESTS FOR DETECTION OF ANTIBODY TO HUMAN IMMUNODEFICIENCY - VIRUS.

Barriga A Gustavo*; Peredo L.V.M.*; Castillo, T.M.*, Herrera, L.R.* Hospital de Infectologia, Centro Médico La Raza, I.M.S.S. Ciudad de México, México.

Objetive To compare two confirmatory tests in the serological diagnosis of-- infection with A.I.D.S. virus.
Methods. 237 sera and 25 c.s.f. from the same number of people that were selected on the basis of screening enzyme immunoassay reactivity to A.I.D.S.-- virus were tested using Indirect Immunofluorescence (I.F.A.) and Immunoblot-assays (W.B.).
Results

GROUP	SAMPLE	I.F.A. No.T./ No.(+)	W.B. No.T./ No.(+)
A.I.D.S. patients	serum	149 / 145	149 / 145
	c.s.f.	25 / 18	25 / 25
Sexual contacts	serum	40 / 39	40 / 39
Hemophiliacs	serum	23 / 22	23 / 22
Blood donors	serum	11 / 9	11 / 9
Renal insuficiency	serum	11 / 8	11 / 5
Lupus erithematosus	serum	3 / 3	5 / 10

Conclusión there was 100% agreement between I.F.A. and W.B. test in the samples of serum of A.I.D.S. patients, their sexual contacts, haemophiliacs and blood donors However the W.B. was the most acceptable method for the groups of patients with renal insuficiency, lupus erithematosus and the samples of- c.s.f. of. A.I.D.S. patients.

W.B.P.169 RESOLUTION OF INDETERMINATE HIV WESTERN BLOT RESULTS BY ADDITIONAL TESTING

Carlson, James R. and Yee, JoAnn L.
University of California, Davis, USA.

Objective. Current laboratory practice for the serological diagnosis of HIV infection involves initial screening of the specimen for anti-HIV antibody using an enzyme immunoassay (EIA) and validation of EIA positive results with Western blot (WB). The resolution of indeterminate WB results is a major problem in this algorithm. A practical solution would be to retest specimens using other serological approaches.
Methods. We have investigated the addition of indirect immunofluorescence (IFA), recombinant EIA (ENV-9, E.I. DuPont, Inc., Wilmington, DE), or recombinant immunoblot (RIBA HIV-216) Chiron Corp., Emeryville, CA) as tests to resolve EIA positive, WB indeterminate specimens.
Results. 508 of 3104 consecutive specimens were EIA positive. WB test results were: 416 positive, 32 negative, 54 indeterminate. The results of additional testing on the 54 WB indeterminate specimens were ENV-9, 2 positive, 52 negative; RIBA HIV-216, 2 positive, 51 negative, 1 indeterminate; and IFA, 1 positive, 41 negative, 11 indeterminate.
Conclusion. These results indicate that the recombinant tests may be the most useful in the resolution of WB indeterminate specimens.

W.B.P.170 PROGNOSTIC VALUE OF REPEATED WESTERN BLOT ANALYSIS.

Kamps, Bernd,S.*; Niese,D.*; Brackmann,H.H.**; Konradt,T.***; Euler,P.**; van Loo,B.**
*Universitätsklinik Bonn, FRG, **Institut für experimentelle Hämatologie, Bonn, FRG, ***Massachusetts Institutes of Technology

Objective. To assess the prognostic usefulness of Western Blot testing in HIV-infection.
Methods. In 214 asymptomatic patients of the Bonn Hemophiliac Cohort Study Western Blot analysis has been performed at intervalls of 3 to 6 months since 1986.
Results. Only loss of anti-p24 or loss of anti-p17 was correlated with clinical progression to ARC or AIDS after 2 years.

	Asympt.	ARC	AIDS (after 2 years)
p24 absent (n=33)	55%	21%	24%
p24 present (n=180)	87%	8%	5%
p17 absent (n=70)	67%	17%	16%
p17 present (n=143)	90%	6%	4%

Conclusion. If available, Western Blot, together with other prognostic markers, might help in deciding which patients to assign to antiretrovial therapy.

W.B.P.171 SENSITIVITY OF A NEW RECOMBINANT INHIBITION TYPE ELISA SYSTEM FOR THE DETECTION OF HIV-1 ANTIBODIES

Van Der Poel, Cees*; Lelie, N.**; Reesink,H.*; Plaisier, A.*; Bakker, E.**; Moshe-Stark, T.*
* Red Cross Blood Bank, Amsterdam, ** Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, Amsterdam, The Netherlands.

Objective. To establish the sensitivity of a new inhibition type ELISA for the detection of HIV-1 antibodies, employing recombinant antigens.

Methods. A serum panel of 1593 confirmed HIV-1 Western Blot positive samples, classified as: clear (n=408), turbid (n=1139), haemolytic (n=46), obtained from asymptomatic individuals (n=1271) and from AIDS patients (n=322), was tested with the new Wellcome recombinant HIV-1 ELISA, according to the manufacturers instructions. The samples had been obtained between 1986 and 1988, and had been stored at -20° C.

Results. Out of 1593, 1589 (99.7%) were found initially positive and 4 samples (0.3%) were found initially negative. Of the ELISA negative samples, 3/4 were classified as haemolytic and 1 as turbid; 4/4 were positive when retested at 1:10 serum dilution. The overall sensitivity of the test was 99.7%. Among clear and turbid samples the sensitivity was 100% and 99.9 % respectively, and among haemolytic samples 93.5 % ($p < 0.001$ Chi sq).

Conclusion. The sensitivity of the Wellcome recombinant inhibition ELISA was very high: 99.7% . The 4 false negative results were observed among haemolytic and turbid serum samples.

W.B.P.172 PERFORMANCE OF A DOT IMMUNOBLOT KIT FOR HIV ANTIBODY TESTING

C.Sherlock[1], D.Cook[1], M.O'Shaughnessy[2], F.Gill[3].
1.University of British Columbia and Provincial Laboratory, Vancouver; 2.Federal Centre for Aids, Ottawa; 3.Canadian Red Cross National Reference Laboratory, Ottawa, Canada.

Objective. To evaluate the performance of a dot immunoblot kit containing recombinant gp160 protein (MGSearch, MicroGeneSys) as a definitive screening and confirmatory HIV antibody test.
Methods. Sera were received for routine testing and were tested at the B.C. Provincial Lab by EIA (DuPont) and immunofluorescence (IFA) and/or Western blot (WB). A true positive was defined as EIA and IFA positive (high-risk patient) or WB positive or both.
Results. 292 sera were tested. Of 216 true positive sera, 196(90.7%) were positive by dot blot (MGS), 6 were negative and 14 were indeterminate (visible dot but no color). Of 76 true negative sera, 75 were negative by MGS and 1 was indeterminate (specificity 98.7%, pos and neg predictive values 100% and 92.6%). 11 known early seroconverters (p24 only on WB) were also tested; of these, 2 were MGS positive, 5 negative and 4 indeterminate.
Conclusion. The figures show that the MGS is insufficiently sensitive to be used as a screening test,particularly for seroconverters. It has good specificity for confirmatory testing. If indeterminate results are recorded as positive the sensitivity improves (97%) but is still inadequate for screening purposes.

W.B.P.173 USE OF AGGLUTINATION ASSAYS SUPPLEMENTAL TESTS FOR ANTIBODY TO HIV.

Tukei, Peter*; J. Nyamongo**; ....B. Mitchell***; E. Muriu*
* Virus Research Centre, Kenya Medical Research Institute, Nairobi
** Blood Bank, National Public Health Laboratories, Nairobi, Kenya.
*** AIDSTECH/Family Health International, North Carolina USA

Objective: To evaluate two agglutination assays for antibody to HIV as supplemental tests in field laboratories in Kenya.

Methods: A particle agglutination test (SERODIA-HIV, Fujirebio,Japan) and a haemagglutination test ([illegible], abbott, USA) were evaluated for use as supplemental tests in comparison with the Western Blot. Seven laboratories in Kenya participated in the study. Serum from 2,000 blood donors, persons at high risk and suspected AIDS patients were initially screened by the HIVCHEK (Dupont, USA), all positive specimens and 10% of the negatives were tested by Western Blot. Each test is being evaluated for sensitivity, specificity, and usefulness in these field laboratories.

Results: With thorough training these tests can readily be performed in laboratories without sophisticated equipment. Data on sensitivity and Specificity will be presented at the conference.

Conclusions: The agglutination tests do not require expensive equipment or highly trained staff and are more economical than the conventional supplemental tests used in HIV testing. These tests offer an alternative to the Western Blot technique as well as their intended use as screening tests.

W.B.P.174 PERFORMANCE APPRAISAL OF LABORATORIES TESTING DRIED BLOOD SPOT SPECIMENS FOR BLINDED HIV SEROPREVALENCE SURVEYS IN THE UNITED STATES

*Hannon, Harry; *Lewis, S.; *McGee, S.; **George, R.; **Pappaioanou, M.
*Center for Environmental Health and Injury Control, and **Center for Infectious Diseases, Centers for Disease Control, Atlanta, Georgia USA.

Objective. To determine and monitor the quality of analytical performance for HIV antibody analysis of dried blood spots (routinely collected for newborn screening programs) by laboratories participating in the blinded seroprevalence surveys of childbearing women.
Methods. Dried blood spot (DBS) specimens on filter paper were prepared simulating typical analytical experiences for the performance evaluation of laboratories. A panel of 59 DBS specimens were prepared from individual serum matrices using heat inactivated HIV positive plasma and negative serum. The first monthly test sets of 12 blind-coded specimens selected from this panel were distributed to laboratories in July 1988.
Results. Two of 7 laboratories misclassified three different specimens in an initial pilot evaluation of the specimen panel. To date, 31 laboratories and 6 manufacturers have analyzed several sets of 12 blind-coded DBS specimens selected from the panel. The participating laboratories have analyzed a total of 1,236 specimens by EIA and Western blot. For the 6-month evaluation period, nine specimen misclassifications and 10 transcriptional errors have been identifed.
Conclusion. The performance of the testing laboratories and products for analysis of DBS specimens has been excellent. These laboratory evaluations assure the quality of the analytical data for the national surveys.

W.B.P.175 ASSESSMENT OF DRIED BLOOD SPOT QUALITY CONTROL AND PERFORMANCE EVALUATION MATERIALS FOR NATIONAL HIV SEROPREVALENCE SURVEYS

McGee, Susan; Hannon, H.; Lewis, S. Center for Environmental Health & Injury Control, Centers for Disease Control, Atlanta, Georgia, USA.

Objective. To characterize dried blood spot (DBS) materials prepared for quality assurance of laboratories screening for HIV seroprevalence. Methods. DBS specimens were produced, characterized, and distributed for bench level controls and laboratory evaluation. Quality control (QC) materials were prepared on filter paper using HIV seropositive plasma and/or negative serum combined with red blood cells to an hematocrit of 50%, to yield appropriate target values of high, low, and negative specimens. Bulk production lots of QC contained 6,000 sheets of 15 DBSs each for routine use by all laboratories. Stability in both longitudinal and accelerated studies and homogeneity of DBS materials were measured by ELISA and Western blot. Results. Analysis of DBS materials, stored at -20°C in zip-closure bags with desiccant over seven months showed no apparent change in optical density (OD) or Western blot band pattern. Studies of antibody stability with a 1.2 OD specimen under various storage conditions were conducted. For example, exposure of this specimen to 37°C at ambient humidity resulted in a 20% reduction of recoverable antibody (relative OD) in 30 days, while the same specimen maintained at 37°C in a zip-closure bag with desiccant showed a 20% relative loss after 61 days. From Western blot analysis the detected titer loss appears to be uniform across all antibody bands. Conclusion. DBS materials can be prepared that are reliable and stable under normal storage and handling conditions for routine QC, and to monitor and evaluate laboratory performance for this matrix.

W.B.P.176 CHRONIC HIV INFECTION WITH DELAYED APPEARANCE OF ANTIBODIES BY USUAL TECHNIQUES AND A CASE OF SEROREVERSION

McLaughlin, Bernadette*; Major, C.*; Swantee, C.*; Brunton, J.**; Read, S.***
*Ontario Ministry of Health, **Mount Sinai Hospital, *** Hospital for Sick Children, Toronto, Ontario, Canada

We describe 2 unusual serology profiles from HIV-infected persons. Case 1: A 47 year old male, was intermittently symptomatic for a year, but not seropositive. The P24 Ag capture Assay was persistently reactive. HIV was isolated in 09/88. Case 2: A 33year old female who presented an acute HIV encephalopathy and was seropositive. She recovered clinically, became EIA negative, IB indeterminate and later developed multiple infections, T4 cell count fell to 40, HIV isolation was positived. A recombinant-based EIA test showed persistent presence of antibodies in both cases.

Results.

	Case 1				Case 2				
	09/87	11/87	07/88	09/88	05/87	06/87	03/88	08/88	09/88
EIA (Dupont)	-	-	±	±	+	+	-	-	-
Immunoblot	-	-	ind	ind	+	+	ind	ind	ind
Recombigen	-	+	+	+	nt	+	+	+	+
P24 Ag (Abbott)	+	+	+	+	nt	nt	+	+	+
HIV Culture	nt	nt	nt	+	nt	nt	nt	-	+

Conclusions. Case 1 adds to the few cases described as HIV infected without the appearance of detectable antibodies for a prolonged period. Case 2 shows that seroreversion with apparent clinical recovery may occur but the infection persists. Standard viral lysate EIA tests may not have the sensitivity to detect HIV antibodies in all cases of infection.

W.B.P.177 REDUCING FALSE REACTIVE RESULTS WHEN TESTING FOR ANTIBODIES TO HIV-I.

*Wolf Prensky, Ph.D., †Manik E. Ganguly Ph.D., †Mark Lifshitz, M.D., *James H. Brassel, M.D., *Daksha Solanki M.Sc., and *Yu Li, M.D. *St. Clares Hospital and Health Center, New York, NY, 10019, and †Dept. of Pathology, NYU Medical Center, New York, NY, U.S.A.

Sera from a population of 40,458 prospective immigrants to the US presently residing in New York City were tested for the presence of antibodies to HIV-I. Screening was with DuPont ELISA and confirmatory testing was with DuPont Western Blot (WB) kits. By WB analysis there were 1,256 (3.1%) reactive and 514 (1.26%) inconclusive (INC) sera.

A sample of 469 INC sera were further tested by alternative FDA approved ELISA assays from Genetic Systems (GS), Ortho, and Abbott. Retesting by the GS ELISA assay reduced the number of reactive samples by 47%, by the Ortho assay by 74%, and by the Abbott assay by 94%. The Abbott assay is therefore the most appropriate second tier ELISA assay for reducing the number of false positive ELISA assays.

The Ortho-Chiron RIBA confirmatory test found 35% of the INC sera to be non-reactive. Confirmatory Cellular immunofluorescence assays using slides prepared by either the Wampole Laboratory, or by Electronucleonics, were applied to a a subsample of the INC sera. These assays reduced the frequency of inconclusive results by over 98% each.

W.B.P.178 INTERPRETATION AND FOLLOW-UP OF "INDETERMINATE" WESTERN BLOT(WB) TEST RESULTS

Argirova,Radka;Bodjeva,E.;Ivanova,V.;Beshkov,D.; Troshev,O.
Central AIDS Lab.,Institute for Infectious and Parasitic Diseases,Bulgarian Medical Academy,Sofia,Bulgaria

Objective. To describe the follow-up of "indeterminate" in WB test persons.
Methods. 53 "indeterminate" persons (16 belonging to high risk and 37 - to low risk groups) were followed-up for 6-14 months (3-8 sera tested in 4-6 week intervals) using- WB HIV-1 IgG (DuPont,USA).
Results. The most characteristic patterns of "indeterminate" WB in low risk persons at the beginning of the study include predominantly antibodies to GAG or ENV proteins(54,05%); they persist or disappear during the follow-up. The sera of high risk people demonstrate at the beginning of the study mainly multiple bands(81,2%) showing a tendency to persist or to shift to "positive" pattern.
Conclusion. 1. "Indeterminate" WB is not a final result. Based on the literature and our experience we proposed an own schema (it will be presented) for diagnostic behaviour to "indeterminate"WB results. 2. People belonging to high risk groups have to be retested in 6-8 week intervals,but not at 3-6 months as recommended until now.

W.B.P.179 EVALUATION OF TWELVE COMMERCIAL KITS FOR SCREENING OF HIV-1 ANTIBODIES IN MEXICO

Soler C*, Mosqueira C**, Morales C**, Valdespino JL** and Sepúlveda J**
*Institute of Biomedical Research, National University of Mexico
**Ministry of Health of Mexico

Objective: To evaluate sensibility, specificity and operative performance of twelve comercial kits for use in screening programs for HIV-1 antibodies in Mexico.
Methods: A 775 sera panel, integrated by 32 AIDS patients sera, 49 HIV-1 seropositive sera, 42 sera from patients with pathologies likely to produce false positive results and 652 randomly selected blood donor sera, was used. The sera were analysed by seven enzime immunoassays from Abbott, Behring, Cambridge Bioscience, DuPont, Heber Biotec, Ismunit and Organon, DuPont dot immunoassay, Abbott, Cambridge Bioscience and Miles passive agglutination assays, and the Medicorp cytoimmunoenzymatic assay. First time reactive sera were retested with the same assays. Commercial Western Blot was used as reference test.
Results: HIV-1 seroprevalence for the total panel was 10.7%. Sensitivities of the assays ranged from 91.8 to 100%; specificities from 96.4 to 100% and operatively (evaluated by operative indicators) ranged from 27.5 to 90%.
Conclusion: Methodological differences between the assays was not relevant for either sensitivity or specificity. Specificity was related to antigen origin. Kits with recombinant antigen gave, in general, higher specificity values.

Psychiatrie/Neuropsychologie
Psychiatry/Neuropsychology

W.B.P.180 Neuropsychological Function in Physically Asymptomatic HIV Seropositive and Seronegative Gay/Bisexual Men

Belsky-Barr,Deborah* ; Perry,S*; Sweeda R+; Barr,W+; Jacobsberg,L*
*Cornell Medical Center, +Long Island Jewish Medical Center, U.S.A.

Objective: To determine if HIV-induced neuropsychological impairment occurs prior to physical manifestations of immunosuppression.
Methods: A 2-hour battery of standardized neuropsychological tests was administered to 20 HIV seropositive and 20 HIV seronegative gay/bisexual men matched for age, education and distress (BDI, Spielberger Anxiety). Asymptomatic status was ensured by thorough medical history and physical exam, and subjects were excluded with psychopathology, substance dependence (SCID, PDE), bereavement (PERI), medication during past month, or history of concussion or migraine.
Results: Multiple t-tests and logistical regression failed to find significant differences between the two groups on attention, concentration, memory, conceptualization, language or motor functions.
Conclusions: The findings further document the need for careful screening and tightly-matched seronegative comparison subjects before concluding that neurotropic effects of HIV cause significant dysfunction in asymptomatic seropositive subjects.

W.B.P.181 IMMUNOLOGICAL AND PSYCHOLOGICAL PREDICTORS OF DISEASE PROGRESSION IN GAY MALES AT RISK FOR AIDS

Fletcher, Mary Ann*; Ironson, G.**; Laperriere, A.*; Simoneau, J.*; Klimas, N.*; and Schneiderman, N.*
*University of Miami, Miami, FL, USA; **Stanford University, Palo Alto, CA, USA

Objective. To determine the immunologic and psychologic factors which appear to be useful predictors of progression of HIV-1 infection.
Method. A cohort of 24 gay males (participants in a larger study, in which they received their anti-HIV-1 status), were followed for 1 to 2 years. Six of these progressed in severity of illness, five who were positive progressed in disease, i.e., developed posterior cervical nodes, two developed symptoms of ARC, two developed AIDS (1 died), and one who was antibody negative seroconverted to positive. Those who progressed in disease differed on several immunologic and psychological measures collected at baseline.
Results. Those who progressed in disease were lower at baseline than those who remained asymptomatic in T4 number, 4B4+T4+number, T4/T8 ratio and lymphocyte response to mitogens. Within a subset of subjects who were antibody positive those who progressed in disease were significantly lower (by Mann-Whitney U Test) than those positive subjects who did not progress in terms of WBC count [(4300 vs 6350)$Z=1.96$, $p=.048$)], total lymphocyte count [(2400 vs 3212)$Z=2.45$, $p=.01$)], T4 number [(706 vs 1200)$Z=2.2$, $p=.027$)], 4B4+T4+ number [(203 vs 554)$Z=2.2$, $p=.027$)], NKH.1 [(186 vs 450)$Z=2.12$, $p=.034$)], number of B cells [(152 vs 301)$Z=2.45$, $p=.01$)], and significantly higher in IgM [(123 vs 87)$Z=1.96$, $p=.05$)].

For the psychological parameters those who progressed in disease, compared to those who remained asymptomatic were lower on active coping, hardiness-commitment, hardiness-total, and social support-reassurance, and higher in loneliness at baseline. Within a subset of subjects who were antibody positive, those who progressed in disease were significantly lower (by Mann-Whitney U Test) on active coping [(11.0 vs 14.5)$Z=2.26$, $p=.023$)], hardiness-commitment [(1.1 vs 1.2)$Z=2.46$, $p=.01$], and hardiness-total [(97 vs 110)$=1.96$, $p=.05$)].
Conclusion. Both immunologic and psychosocial factors may be predictors of disease progression in HIV-1 infection. Supported by NIMH, P50MH42455-03.

W.B.P.182 A COMPARISON OF NEUROPSYCHOLOGICAL TESTING AND MENTAL STATUS EXAM IN AIDS PATIENTS

Kobayashi, Joyce*; Heaton, R.**; Thompson, L.*; Norton, I.*; Cohn, D.* *University of Colorado, Denver, Colorado USA
**Univ. of California, San Diego, California USA.

OBJECTIVE: To document the inaccuracy of a standardized mental status exam compared to neuropsychological (NP) testing in the assessment of cognitive function in people with AIDS.
METHODS: NP testing (Numerical Attention; Symbol-Digit; Trails A, B; Story Recall and Figure Learning) and the NBCSE (Neurobehavioral Cognitive Status Exam) were done on 31 Ss with AIDS who were not referred for neurological problems. NP test results were compared to 39 controls.
RESULTS: According to the NBCSE, a standardized mental status exam, 28 of 31 Ss with AIDS were normal(21) or had an abnormal score only in memory(7). NP testing revealed impairment in 17 of these subjects, 11 of whom were very impaired on summary scores. Ss with AIDS were significantly impaired, compared to controls on Numerical Attention Time ($p<.001$), Symbol-Digit Modalities ($p<.002$), Trails A ($p<.04$), Trails B ($p<.04$), Story Recall ($p<.003$), and Figure Learning ($p<.006$).
CONCLUSION: In Ss with AIDS, a standardized mental status exam may identify deficits in memory, but will not accurately assess cognitive dysfunction which is significantly impaired across multiple categories, compared to controls.

W.B.P.183 NEUROPSYCHOLOGICAL IMPACT OF AIDS ON THE DEVELOPING BRAIN

Coffman, Hugh; Kemmerer, B.; Gioia, G.
Harvard Medical School/Children's Hospital, Boston, MA USA

Objective. To propose a model for understanding the neuropsychological development of children with HIV infection, highlighting the differences between insult to the developing CNS and the mature adult CNS.
Method. A developmental neuropsychological perspective, with attention to white matter disorders (Rourke, 1988) is applied to 1) previous empirical findings and 2) current results on 16 children with HIV infection (10 treated with AZT) seen for serial comprehensive neuropsychological assessments.
Results. Infants with CNS involvement exhibit more global neuropsychological deficits whereas children with later or acquired manifestations show greater functional variability with specific deficits observed in attention and intermodal integration as represented by constructional and memory impairments.
Conclusion. The developmental neuropsychological model provides perspective on adult/child differences in CNS pathology. While similarities exist in functional deficits, the dementia symptomatology in adults is a result of the insult to the mature CNS causing specific loss of established functions. In contrast, the global effects in infants and the specific attentional and integration deficits in children result from poor transmission/connection between underdeveloped brain systems. Cognitive sequelae of HIV infection and the effects of AZT therapy in infants/children will be related to the developmental timing of both the CNS manifestation and treatment. The specific nature of the neuropsychological deficits present a major challenge to caregivers and educators who will provide services for growing numbers of children with AIDS.

W.B.P.184

W.B.P.185 MOOD STATE, NEUROPSYCHOLOGY & SELF REPORTED COGNITIVE DEFICITS IN HIV INFECTION

Herns, M., Newman, S., McAllister, R., Weller, I. and Harrison, M, UCMSM, London U.K.

Objective: To examine the relationships between mood state, neuropsychological performance and self reported cognitive deficits in HIV+ve homosexual males.
Method: 32 -ve and 77 well, +ve (CDC 2 + 3) were assessed using a comprehensive neuropsychological battery. Self reported and observer rated measures of mood were completed at the same time, and self reports on cognitive performance were also obtained.
Results: No differences were found between the two groups on the neuropsychological tests. They differed significantly on anxiety and on depressed mood, the +ve obtaining higher scores on both. On a measure excluding items relating to physical illness, the difference between the groups approached significance. Mood state made only a small contribution to overall neuropsychological performance. Subjective reports of cognitive deficit were in general not related to actual neuropsychological performance, but rather, were significantly associated with anxiety and depressed mood.
Conclusions: No differences were found between the groups on neuropsychological assessment. The seropositives had higher scores on the depressed mood and anxiety. Self-reported cognitive defects were associated with measures of mood state and not neuropsychological performance.

W.B.P.186 NEUROPSYCHIATRIC DISTURBANCES IN HIV-INFECTED PATIENTS.

Cairoli, Silvano*; Verri, A.P.*; Barbarini, G.**; Parisi, A.**; D'Avola, G.* and Cerutti, P.G.*
*3rd Dept.of Neurology, IRCCS C.Mondino and **Dept.of Infectious Disease, IRCCS Policlinico S.Matteo, University of Pavia, 27100 Pavia, Italy.

Objective. To describe frequency, type, severity of affective/behavioral disturbances among HIV-infected patients in the different stages of the disease; to evaluate the personality traits of these patients.
Methods. The study included n. 113 subjects (M=77; F=36; mean age 26.9±5.4 yrs; i.v.drug abusers n.96/113) of consecutive observation, classified according to the CDC criteria (group II: n. 49; III: n. 32; IV A: n. 10; IV B-E: n. 22). The following tests were administered: BPRS (Brief Psychiatric Rating Scale); MADS (Montgomery-Asberg Scale for Depression); MMPI.
Results. Affective/behavioral abnormalities were diagnosed (DSM III-R) with progressive percentual increases from group II to group IV, ranging from "adaptive" anxiety/depression to major psychiatric disturbances as a part of Organic Brain Syndromes. Anxiety/depression scores, even if abnormally elevated in all groups, tended to decrease with progression of the disease (scores of group IV vs II: $p< 0.01$); a significant elevation ($p<0.001$) of "Pd" scale (MMPI) was found without differences among CDC groups.
Conclusions. Personality traits of our HIV-patients were superimposable to those of HIV-negative drug abusers (control population); attention should be given to asymptomatic HIV-subjects showing even minor psychiatric disorders due to their possible significance of (HIV-related) organic mental disorders.

W.B.P.187 PSYCHOMETRIC EVALUATIONS IN ZIDOVUDINE TREATED PATIENTS - STANDARDIZED TEST-PROCEDURES DEMONSTRATE MEASURABLE PSYCHOLOGICAL IMPROVEMENT

Jäger, Hans; Franke, G.
AIDS-Study Group, Schwabinger Krankenhaus, Munich, FRG.

Objective. To evaluate the psychosocial impact of Zidovudine treatment in ARC and AIDS, 40 patients were sequentially tested using the SCL-90-R, a psychological symptom index. Medical, immunological and sociodemographic data were collected, in addition patients were staged using the Walter-Reed-Staging Classification.
Methods. 20 patients receiving Zidovudine were compared to a group of 20 patients in similar stages from the pre AZT area. We used a three point design of sequential tests. The SCL-90-R was applicated more than 2 months before the first medication of Zidovudin (point 1), within 3 months after the first medication (point 2) and more than 6 months after starting therapy (point 3). The patients in the historic comparison group had been tested at comparable points of their disease between 1986 and May 1987 when Zidovudine became first available in West-Germany.
Results. 20 Patients receiving Zidoduvine showed considerable less psychosocial distress within 3 months and more than 6 months after the first medication than before being started on this drug (p < = 0.05). On the other hand we found rising psychological distress between point 1 and point 2, and between point 1 and point 3 in the comparison group (p < = 0.05). It can be expected that physical improvement in Zidovudine treated patients contributes to the improvement of psychological stress as well as a feeling of hope related to this medication.
Conclusion. Standardized test procedures demonstrated lower distress in patients receiving Zidovudine than in the same patients before their being started on this drug, and than in similar patients not on Zidovudine.

W.B.P.188

W.B.P.189 THE USE OF MEDROXYPROGESTERONE AS PHARMACOLOGIC TREATMENT OF HYPERSEXUALITY IN MALE PATIENTS WITH HIV-1 INFECTION

Schaerf, Frederick W., Koenig, T., Wisner-Carlson, R. and Berlin, F. The Johns Hopkins Hospital, Baltimore, MD, USA

Objective: To examine the efficacy of the anti-androgen medroxyprogesterone acetate (MPA, Depo-Provera) in reducing sexual urges and high-risk behavior in patients with hypersexuality and HIV-1 infection.
Methods: Four HIV-1 seropositive male patients aged 22-44 were seen in psychiatric consultation for suspected or self-reported hypersexuality. After inpatient or outpatient evaluation, all were begun on MPA. Three received 500 mg. IM every 1-2 weeks while the fourth received oral Provera, 90 mg. every day. Determination of efficacy was based on self-report regarding intensity and frequency of sexual urges and/or reports of sexual behavior. Patients were seen weekly and received individual psychotherapy.
Result: Two patients were diagnosed with paraphilic disorders while the other two engaged in sexual behavior in the setting of poor judgement related to mental retardation. FSH/LH levels were increased in one patient with low testosterone. All patients decreased the number of sexual contacts, falling from as many as 50 per week to 1 per week or complete celibacy. This effect was noted after approximately 6 weeks on the drug. The only untoward event was mild hypertension in one patient.
Conclusion: Individuals engaging in high-risk sexual behavior due to either paraphilia or poor judgement secondary to mental retardation can decrease their urges and behaviors with MPA. Therefore, MPA should be considered as a safe and effective treatment option in these patients when combined with psychotherapy.

W.B.P.190 NOREPINEPHRINE RESPONSE & IMMUNE FUNCTIONING IN HIV⁺ SUBJECTS

Mahendra Kumar; R. Morgan; M.A. Fletcher; A.M. Kumar; J. Szapocznik and C. Eisdorfer
The Biopsychosocial Center on AIDS, University of Miami, School of Medicine, Miami, Florida, U.S.A.

"Stress" is one of the proposed cofactors that could influence the clinical course in HIV infection. This study of 43 HIV+ homosexual males examines the hypothesis that norepinephrine (NE) response to a cold pressor test is related to immune functioning in HIV⁺ subjects.

A sample of blood for determining PHA stimulation of lymphocytes was collected from each subject via an indwelling catheter. After a 30 min rest, another sample was drawn for quantifying NE (basal level). Subjects then emersed one hand in ice water. Three additional blood samples were drawn at 0 (peak), 2 and 4 minutes after removing their hand from the water. NE response was expressed in terms of its recovery index (RI) from the peak level. RI = (peak - final sample)/(peak - basal sample). The results using a Pearson linear test show a relationship between RI and lymphocyte PHA stimulatory index ($r = .47$; $p < .005$).

These data support the hypothesized link between stress response and immune function. They also suggest that RI may be a useful indicator of stress response.

W.B.P.191 RESPONSE TO ANTIDEPRESSANT THERAPY IN DEPRESSED PERSONS WITH ADVANCED HIV INFECTION

Francisco Fernandez*; Levy, JK*; Mansell, PWA**
*Baylor College of Medicine; **M.D. Anderson Cancer Center, Houston, Texas USA

Objective: To determine differences in therapeutic response to two antidepressants in advanced HIV infection.
Method: Twenty-eight subjects (19 ARC/9 AIDS) were selected as meeting DSM-III-R criteria for major depression. Subjects received either amitriptyline (AMI) or desipramine (DMI) in a randomly assigned fashion. The patients were followed for the study period of one year. The Clinical Global Improvement Scale (CGIS) was used to rate response of the patients' psychiatric disorder to the medications.
Results: Using chi-square analyses and Fisher's Exact Test, ARC patients showed significantly better response (CGIS of moderate to marked improvement; p=0.0261). No significant difference was found between responses to the two antidepressant agents (p=0.2945).
Conclusion: Our results suggest:

1. In spite of the differential antidepressant affinities for central neurotransmitter receptors, specifically H_1 and muscarinic blockade, both DMI and AMI were equivalent in their clinical efficacy and tolerance.
2. The significant difference found between ARC and AIDS patients to antidepressant treatment may reflect a higher fraction of the organic component of AIDS-related mood disorder.

W.B.P.192 NEUROPSYCHOLOGICAL MANIFESTATIONS OF HIV INFECTION IN GAY MEN

Stern, Yaakov; Sano, M.; Goldstein, S.; Mindry, D.; Richards, M.; Todak, G.; Williams, J.B.W.; Ehrhardt, A.; Gorman, J. &*
HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, New York, NY, U.S.A. *Rabkin, J.

Objective: Cognitive function in HIV+ individuals without AIDS may be impaired. However, prior studies have been limited by inappropriate control groups and failure to medically stage HIV.
Methods: Blind to HIV status, we administered tests assessing general intellectual function, memory, language, executive function, visuospatial abilities, attention and motor speed to 160 gay men: 40HIV-, 55 HIV+ asymptomatic, 33 mildly symptomatic and 32 with medical symptoms.
Results: HIV+ and HIV- men were comparable in age, education, race, and handedness; presence of neurological signs, current or previous psychiatric diagnoses, rated depression or anxiety; and frequency of defective neuropsychological performance based on normative values or clinical impression. HIV+ men performed worse than HIV- on a test of verbal memory, had more trouble getting into set on a test of executive function, made more errors on the trail making test and had slower choice reaction time (all p<.05). Within the HIV+ groups there was no degradation in performance across medical stages of severity, but a summary score of neuropsychological performance correlated with both T4/T8 ratios and a rating of the severity of neurological signs and symptoms (both p<.05).
Conclusion: Subtle non-specific changes in memory, executive function and attention can occur after HIV infection of the CNS, prior to the onset of medical symptoms. Overt dementia or other major cognitive disorders do not appear at this stage of HIV infection unless caused by another disease.

W.B.P.193 THE USE OF THE MINI MENTAL STATUS EXAM AS A COGNITIVE SCREEN IN PATIENTS WITH AIDS

Dilley, James W., Boccellari A.; Davis A.
San Francisco General Hospital, University of California San Francisco School of Medicine, Dept. of Psychiatry and UCSF AIDS Health Project, San Francisco, California, U.S.A.

Objective. To examine the utility of the Mini Mental Status Exam (MMSE) as a screening instrument in detecting cognitive deficits in patients with AIDS.

Methods. Hospitalized subjects (N=50) with first episode *Pneumocystis carinii pneumonia* (PCP) were given a battery of 10 neuropsychological tests (NP), Auditory Brain Wave Evoked Potentials (ABR's), and the MMSE. Impairment on the MMSE was determined by the usual cut off score of <24.

Results. Sixty-six percent of the subjects had abnormal ABR's and 78% of the subjects were abnormal on at least 6 of the 10 NP measures. However, only 4 of the 50 subjects (8%) scored less than 24 on the MMSE. The $\bar{X}$ score for this sample was 26.6, SD=2.0. In addition, the MMSE did not correlate with any of the individual NP measures nor with the ABR's.

Conclusions. The MMSE appears relatively insensitive in identifying cognitive deficits in patients with HIV infection. Caution should be exercised in using the MMSE to rule out cognitive impairment in this population.

This work has been supported in part by grant # DA04873 from the National Institute on Drug Abuse.

W.B.P.194 TRYPTOPHAN LEVELS ARE UNRELATED TO DISTURBANCES OF MOOD IN HIV-1 INFECTED PATIENTS

Keilp, John G.*; Brew, BJ.*; Heyes, M.**; Sadler, AE.*; Price, RW.*; Sidtis, JJ.*. * Memorial Sloan-Kettering Cancer Center, NY, NY; ** National Institute of Mental Health, Bethesda, MD, USA.

Objective: Disturbances of mood frequently accompany early symptoms of the AIDS Dementia Complex (ADC). Metabolism of tryptophan (TRYP), a serotonin precursor, is also disrupted by HIV-1 infection. In order to investigate a possible biochemical mechanism of mood disturbance in ADC, mood and psychiatric symptom ratings were related to TRYP levels in both plasma and cerebrospinal fluid (CSF) in HIV-1 infected patients.
Methods: Blood and CSF samples from 45 HIV-1 infected patients, at various stages of disease, were assayed for TRYP using high performance liquid chromatography. Samples were drawn following administration of the Neuro-AIDS Study Group neurological history, exam, and neuropsychological battery, which included self-ratings for mood disturbance (Profile of Mood States: POMS) and general psychiatric symptomatology (Brief Symptom Inventory: BSI).
Results: Correlations between mood/psychiatric ratings and both plasma and CSF tryptophan levels were non-significant (e.g. POMS total by plasma TRYP r=-.03, p=.82; POMS total by CSF TRYP r=-.17, p=.25; BSI general severity index by plasma TRYP r=.17, p=.27; BSI general severity index by CSF TRYP r=.20, p=.22). Cases above normative cutoffs for mood/psychiatric disturbance did not differ in tryptophan levels from those below these cutoffs.
Conclusions: Levels of tryptophan, a precursor of serotonin, are unrelated to both presence and severity of self-reported mood disturbances in HIV-1 patients.

W.B.P.195 NEUROPSYCHOLOGICAL AND IMMUNOLOGICAL ABNORMALITIES IN ADVANCED HIV INFECTION

Fernandez, Francisco; Levy, JK; Pirozzolo, FP
Baylor College of Medicine, Houston, Texas, USA

Objective: To study the relationship between systemic immunodeficiency status and neurobehavioral impairment in advanced HIV infection.
Methods: Eighty subjects (39 ARC/41 AIDS) studied at entry for baseline neuropsychological testing were evaluated for their hematological and immunological status (white blood cell count, absolute T-cell count, and T-helper/T-helper suppressor lymphocyte ratio). Correlational analysis was done between neuropsychological marker variables with hematological and immunological values. Investigators were blinded to the individual participant's disease status.
Results: No significant differences between ARC or AIDS with respect to age, education, socioeconomic status or substance use were present. Abnormalities in memory reflected by long-term storage (LTS) and consistent long-term retrieval (CLTR) revealed significant abnormalities in both groups: 62% of ARC and 73% of AIDS cases fell below one standard deviation below the mean on LTS; 92% of ARC and 100% of AIDS cases fell one standard deviation below the mean on CLTR. Likewise, abnormalities were present in visual scanning, information processing and attention. ARC/AIDS status was not significantly correlated with psychiatric diagnoses. No statistically significant correlations were found between neuropsychological markers, ARC and AIDS subjects' total white blood cell count, total T-cell count, and helper/suppressor ratios.
Conclusion: Our results suggest a lack of correlation of cognitive dysfunction and immunological status in advanced HIV infection suggesting that HIV-CNS involvement may be independent of indices generally associated with HIV systemic progression.

W.B.P.196 A BRIEF SCREENING TEST BATTERY FOR COGNITIVE DEFICITS IN HIV INFECTION

Woo, Stephen*; Hunter, J.*; Wang, P.*; Simor, A.*; Wortzman, G.*; Fernandes, B.*; Bury, A.*
*Mount Sinai Hospital, University of Toronto, Toronto, Ontario,Canada

Objective. (1) To design a brief screening measure with the capacity for early detection of neurocognitive impairment in HIV infected individuals.
(2) To establish if scores on this measure may be used to infer the degree of CNS or immune impairment.
Methods. This is a 2 year longitudinal study of a case group with HIV infection (Ab+ =20, ARC=5, AIDS=7), and a control group, similar in age, education and SES. Neuropsychological tests, and measures of depression and anxiety are administered at 3 month intervals. The battery includes: Trails A and B, Controlled Oral Word Association, Graded Difficulty Arithmetic, WAIS-R Digit Symbol and Digit Span, Stroop Test, Reye Auditory Verbal Learning Test and Benton Visual Retention. To determine the pathological correlates of cognitive status, blood tests and magnetic resonance imaging (MRI) are done every 6 months.
Results. Initial testing and 3 month follow-up show no global differences between cases and controls. However, 30% of the cases scored in the range of suspected of impairment on atleast 1 test, and 57% of subjects with AIDS have scored in this range on 2 tests or more. Trails A and B show poor performances across the spectrum of HIV infection with many scores falling between 1 and 2 standard deviations below the mean.
Conclusion. These preliminary results suggest some cognitive changes associated with HIV infection which appear to be greater in patients with AIDS. NHRPD Grant#6606-3654-AIDS.

W.B.P.197 DRUG USE HISTORY IN GAY MEN WITH AIDS AND ITS RELATION TO NEUROPSYCHOLOGICAL FINDINGS

D. SanGiovanni, A.Boccellari, James W.Dilley, A.Davis, San Francisco General Hospital, UCSF School of Medicine, San Francisco, California. U.S.A.

Objectives: To characterize the drug use histories of gay men with AIDS and to explore possible interactions of drug use with neuropsychological (NP) findings.
Methods: Self reported drug use histories for the prior 6 months and prior 7 years were obtained from 46 gay men during their first hospitalization for AIDS. The Beck Depression Inventory was given. The length of time that AIDS related symptoms were experienced prior to hospitalization was measured. NP measures given were: Wechsler Memory Scale-Russell version, Shipley, Trail Making Test, and Finger Tapping Test. A sum of z was calculated for the NP measures to represent an overal index of impairment.
Results: Drug use was reported by 43 of the 46 subjects (93%). Alcohol and marihuana use represented the highest consumption. Average alcohol use for the past 6 months was once a week, and for the 7 year period was 2-6 times a week. Average marihuana use for the past 6 months was once a month and for the 7 year period 2-3 times a month. A significant decrease (p<.05) in drug use was found in 6 out of 10 drug categories from the 7 year to 6 month period. Marked NP impairment was found in 78% of the sample, irrespective of amount of drug use. A multiple correlation was not significant between the NP index of impairment and a combined drug use score, after partialling out the measures of depression and symptom length.
Conclusions: Subjects at risk for AIDS or showing early signs of AIDS reported a significant decrease in drug use over the last several years. This may be due to increasing health concerns and awareness of AIDS. Furthermore, light to moderate substance use (a few times weekly or less) does not appear to have exacerbated the marked NP impairment found in this sample.

W.B.P.198 RELATIONSHIP BETWEEN NEUROPSYCHOLOGICAL AND IMMUNE VARIABLES IN HIV POSITIVE ASYMPTOMATIC MEN

Dilley, James W., Boccellari A.; Davis A.; Moss, A.; Bacchetti P.; and Young, M.
San Francisco General Hospital, University of California San Francisco School of Medicine, Dept. of Psychiatry and UCSF AIDS Health Project, San Francisco, California, U.S.A.

Objective. To describe the interrelationship between neuropsychological (NP) function, immune status and neuropsychiatric measures in asymptomatic HIV positive gay men.

Methods. Fifty-six asymptomatic gay men (HIV+ = 33, HIV- = 23) were given a one time battery of NP tests and psychiatric rating scales. Measures of immune function were also obtained. Group differences between HIV+ and HIV- groups were determined by use of multiple T-tests. (Bonferroni correction was applied.) Additionally, the HIV positive group was divided into those with CD_4 cells ≤ 400 (N = 14) and >400 (N=19). Correlations were calculated between the immune and NP measures.

Results. 1. No significant differences were found between the positive and negative groups on age, education and occupational levels. 2. No statistically significant differences were found between the HIV+ and HIV- groups on any of the NP measures. 3. In the HIV+ group, no statistically significant differences were found between those with CD_4 ≤ 400 and those with CD_4 > 400 on the NP measures. Additionally, no differences were found on the NP measures between the CD_4 ≤ 400 group and the HIV negative group.

Conclusions. These results help to confirm a lack of documented neuropsychological impairment in otherwise asymptomatic HIV+ men. This finding held up even when comparing those HIV+ men with CD_4 count of ≤400 with the seronegative group.

This work has been supported in part by grant # DA04873 from the National Institute on Drug Abuse.

W.B.P.199 COGNITIVE DYSFUNCTION AND PSYCHOSOCIAL FACTORS IN SYMPTOMATIC SEROPOSITIVE MEN

Temoshok, L.; Canick, Jonathan P.; Sweet, D.M.
University of California School of Medicine, San Francisco, CA., U.S.A.

Objective. Questions remain about the prevalence and severity of cognitive impairment along the spectrum of HIV disease. Our aim was to determine the presence and degree of cognitive impairment in symptomatic seropositive men, and whether severity was associated with certain psychosocial factors.
Methods. 103 seropositive homosexual men with at least one HIV-related symptom were recruited from the UCSF AIDS Clinic and administered neuropsychological tests. Data were adjusted for age and education, and standardized ratings of impairment were determined. Standard measures of distress, coping, and mood were also administered.
Results. 89% of Ss showed at least mild impairment, 59% at least moderate impairment, 32% at least marked impairment, and 19% severe impairment on one or more neuropsychological test. There was also differential cognitive impairment: e.g., 43-49% had impaired immediate and delayed memory, but only 17% had impaired verbal fluency; while only 18% had impaired total digit span, 28% had impaired digits backwards. Anger/Hostility was correlated with level of impairment on most tests ($r = .19$ to $.31$, $p < .05$ to $.001$). Greater impairment on Digits, Verbal Fluency, and Trailmaking was significantly correlated with coping style: for social desirability, $r = .21$ to $.31$, $p < .05$ to $.001$); for emotional control, $r = .19$ to $.29$, $p < .05$ to $.001$.
Conclusion. Few neurological or neuropsychological reports on patients with HIV disorders have included psychosocial measures. The positive correlations in this sample of distress and coping style with levels of impairment may reflect (a) the exacerbation of cognitive impairment by distress and certain coping styles, and/or (b) patients' reactions to awareness of their cognitive impairments.

W.B.P.200 EARLY DIAGNOSIS OF HIV INFECTION IN INFANTS

d'Arminio Monforte,Antonella*; Novati,R.*; Marchisio,P.**; Zanchetta,N.***; Lazzarin,A.*; Tornaghi,R.**; Massironi,E.**.
*Infectious Dis. Clinic,**Pediatric Dept.V,***Hygiene Dept.IV,Milan Univ.Italy

Objective. To evaluate the role of serial IgM anti-HIV and p24Ag testing in the neonatal diagnosis of HIV infection.
Methods. 24 neonates from anti-HIV pos. mothers were followed-up bimonthly for 10±6 mo.s. At each time clinical, immunological (lymphocyte subsets, immunoglobulin levels) and serological (IgG anti-HIV, ELISA and Western Blot (WB), IgM anti-HIV, WB, p24Ag, ELISA) tests were performed. CDC classification for pediatric HIV infection was used.
Results. IgM anti-HIV were found at birth (5 cases) or at 2nd-4th mo.(6 cases) p24Ag was detected in 7 cases from 4th mo., in 1 transiently at birth. 5 neonates became symptomatic (P-2) within 4th mo. (follow-up 11±8 mo.s). All were IgM anti-HIV and/or p24Ag pos. 3 other neonates developed immunodeficiency (ID) (follow-up 13±4 mo.s). All were p24Ag pos. (P1-B), 2 also IgM anti-HIV pos. Among asymptomatic immunocompetent patients 7 were followed at least for 15 mo.s (16±3 mo.s): 2 were still seropositive (P1-A) (previously IgM anti-HIV pos.) 5 were pos. only for gp120 (1 IgM anti-HIV pos.). 5 patients were followed for 5±3 mo.s (4 IgM anti-HIV pos., 1 also p24Ag pos.); finally 4 neonates are too young to be followed.
Conclusions. IgM anti-HIV and p24Ag seem good predictors of HIV infection and/or disease progression in infants.

W.B.P.201 IMPACT OF HIV DIAGNOSIS ON MOOD - ST.STEPHEN'S COHORT STUDY

Jadresic, Danitza*/**, Riccio, Massimo**, Hawkins D*, Wilson B***, Thompson C****.
*St.Stephen's Hospital, London; **Charing Cross Medical School, London;
***Southampton General Hospital, Southampton;
****Royal South Hants Hospital, Southampton.UNITED KINGDOM

Objective To assess the impact of HIV positivity on mood state.
Method As part of the St.Stephen's prospective cohort study, mood is assessed prior to notification of HIV Ab status and reassessed 6 months later. Assessment consists in the following self-report questionnaires: HAD, POMS, STAI and a Physical Complaints Schedule.
Results The baseline HAD anxiety mean scores fell within the borderline pathological range in both groups (HIV +ves: 9.04±SE0.68; HIV -ves: 8.69±SE 0.60), whereas at 6 months they fell within the normal range (HIV+ves: 7.00 ±SE1.61; HIV-ves: 7.96±SE0.75). Inter- and intra-individual group comparisons, however, were not significant. Other mood scores for HIV+ve and -ve groups were well within the normal range at baseline and follow-up.
Conclusions Reports of clinical impressions indicate that anxiety and/or depression levels rise sharply at the time of diagnosis of HIV+ve status. Our results suggest no evidence of any persistent pathological mood states at 6 month follow-up.

W.B.P.202 A VA HOSPITAL SPECIALIZED PSYCHIATRY PROGRAM FOR PATIENTS WITH HIV DISEASE: A REVIEW OF THE FIRST 50 REFERRALS

Vanderburg, Douglas
San Francisco Veterans Administration Hospital and University of California, San Francisco, U.S.A.

Objective. To identify characteristics of a population of patients with HIV disease referred for outpatient psychiatric consultation in the San Francisco VA Hospital and to use these data for program planning purposes.
Methods. Since the first cases of HIV disease appeared at the San Francisco VA Hospital in 1982, the number of referrals to psychiatry steadily increased. Initially patients were managed on an individual basis, but it eventually became clear that this population had grown to be a significant proportion of overall referrals. A multidisciplinary committee was formed to evaluate the needs of this population and make specific programmatic recommendations. Meetings were held with various hospital units involved in providing care to HIV patients to assist in planning and coordinating psychiatric services. A trial program was initiated beginning July 1, 1988. Between July 1 and December 31, 1988, 50 patients with HIV disease were referred for psychiatric consultation. Demographic and other specific variables were monitored, including reason for referral, DSM-IIIR diagnoses, treatment plan, disposition, medication, and outcome.
Results. Data from this recent 6-month period are in the process of being coded and analysed at the time of abstract preparation and will be presented at the conference.
Conclusion. Conclusions regarding using the data for planning for HIV psychiatric services will be presented.

W.B.P.203 REQUEST OF MENTAL HEALTH-CARE WORKERS INTERVENTION BY PHYSICIANS ATTENDING HIV+ OR AIDS PATIENTS: The importance of an integrated and multidisciplinary approach.

G. Cardoso, M. Tostes, A. Queiroz, A. Navarro, M. Zornitta
Hospital Universitario C.F.F. - Federal University of Rio de Janeiro - National Reference Centre on AIDS - Brazil.

Objective: To identify and evaluate the reasons that make physicians, leading with HIV+ or AIDS patients, to request mental health-care workers approach.
Method: Retrospective review of 124 patients assisted by mental health-care workers from a total of 439 registered patients attended in a National Reference Centre on AIDS, since july 1987.
Results: There were 158 requests to evaluate patients. 27 patients had 2 reasons for evaluation, 2 patients had 3 reasons and 1 patient had 4 reasons. Requests were classified in 6 groups. The results were: 1) Diferential Diagnosis: (19/158):12%; 2) Problems related to clinical staff-patients relationship: (46/158):29%; 3) Reactions to diagnosis and/or evolution of the disease: (59/158):38%; 4) Psychomotor agitation: (10/158):6%; 5) Family approach: (10/158):6%; 6) Other: (14/158) :9%. In each group we could identify several causes of request. The most important were: Anxiety (group 3): (26/158):16%; Difficulties in the communication of the diagnosis to the patient (group 2):(18/158): 12%; diferential diagnosis (group 1) between cognitive deficits (delirium, dementia, depression): (13/158):9%
Conclusions: The high proportion of request (28%) to mental Health-care professionals shows the importance of an integrated and multidisciplinary approach in the assistance of these patients. Although, an adequate preparation is needed for these professionals due to the complexity of the situations that arise: clinical complications, social problems, staff-patient difficulties and multiple mental syndromes manifestations.

W.B.P.204 PERSONALITY, BEHAVIOUR AND COGNITIVE CHANGES IN AIDS AS RATED BY PATIENTS AND THEIR CARERS AND AS RELATED TO NEUROPSYCHOLOGICAL TEST RESULTS.

Hoosis, A.K; Church, J; Veervale, S; and Green, J.
Paterson Wing, St. Mary's Hospital, London, W2 1NY, U.K.

Objectives: To determine if; (1) Informal carers of AIDS patients notice changes in their partners which may be predictive of objective neuropsychological impairment; (2) Patients' own perceptions are correlated with objective neuropsychological impairment.

Method: The informal carers of AIDS patients (N=75) rated the patients for changes on the St. Mary's Personality, Behaviour and Cognitive Changes (PBCC) Questionnaire. These ratings were compared with PBCC self -ratings of the patients and the carers. Scores were compared also with the neuropsychological test results of the patients. In addition carers and patients filled out standardised mood questionnaires.

Results: 1. Carers' ratings of the patients are independent of the carers' own anxiety and depression levels. 2. Carers' ratings of deterioration in patients' cognitive functioning is significantly correlated with an overall impairment score obtained from neuropsychological testing. However, patients' own ratings of impairment in their cognitive functioning is related only to their own anxiety and depression.

Conclusions: Informal carers can be useful informants as to possible Central Nervous System involvement in patients. However, patients' subjective perception of deterioration in themselves is likely to be unreliable.

W.B.P.205 COMPETENCY CONSULTATION TO HIV PATIENTS: A LIAISON PSYCHIATRY PERSPECTIVE

Weissman, Henry; Perton, L.; Agnelli, P.
Queens Hospital Center Affiliation, Long Island Jewish Medical Center, Jamaica, New York, U.S.A.

Objective. 1) To identify the reasons for competency consultation to patients infected with HIV, 2) to classify such consultations by psychiatric diagnosis and 3) to determine if the competency consultation provides a significant access route to mental health care for HIV patients.
Methods. All psychiatric competency consultations to HIV patients at Queens Hospital Center from 1987 and 1988 were evaluated for demographic characteristics, reasons for consultation, competency, psychiatric diagnosis and psychiatric intervention.
Results. In 1987-88 the psychiatric consultation-liaison service saw 56 HIV patients in competency evaluations, representing the largest single medical diagnosis, and constituting 1/3 of all competency evaluations. Forty two percent were referred because they refused treatment, 31% presented with altered mental status, 25% wished to leave the hospital. Forty percent were judged competent. Of the remaining 60%, all but two were diagnosed with organic mental syndrome. Of those judged competent 24% were diagnosed with adjustment disorders, and 19% each personality disorder and substance abuse. Five patients (24%) had no psychiatric diagnosis.
Conclusion. Competency evaluations form a significant portion of psychiatric consultations to HIV patients, reflecting the neuropsychiatric and psychosocial manifestations of the disease. They provide an important route of entry into mental health care.

W.B.P.206 POSITIVITE'A L'HIV EN PSYCHIATRIE: OBSERVATION SUR 18 MOIS.

Zamperetti Marco*;Goldwurm G.F.*;Fernandez I.*;Sassoli V.*
*Servizio Psichiatrico di Diagnosi e Cura "Origgi I°" e Centro di Medicina Comportamentale,Ospedale Cà Granda Niguarda,Milano,ITALY.

Objectif. Nous croyons que la présence des troubles psychiques induise une telle réduction des capacités de jugement d'entraîner plus fréquemment que dans la population générale les typiques conduites à risque pour l'infection de HIV. Pour cette raison nous avons cru utile suivre dans le temps la prévalence des sujets découverts positifs à l'HIV parmi les hospitalisés en Psychiatrie.
Méthodes. Outre la VDRL et l'HBsAg que nous effectuons routinièrement,à partir du 1-10-87 nous avons soumis au test pour l'HIV tous les patients consentants hospitalisés dans notre service. Nous avons utilisé comme groupe de contrôle les donneurs de sang du Centre de Transfusion de la Policlinique de Milan. Enfin nous avons évalué la significativité statistique avec le test du chi carré.
Résultats. Les données à ce moment se referent aux deux premiers semestres d'observation,du 1-10--87 au 30-9-88. On a pu effectuer le test pour l'HIV au 79,4% (259/326) des hospitalisés en psychiatrie (mâles 44,7%;femelle 55,3%;âge moyenne 42,8 a.). Les patients positives à l'HIV dans le premier semestre ont été le 8,4% (12/144) et,à la fin du deuxième semestre,tel pourcentage est devenu le 6,1% (16/259) (mâles 75%;femelle 25%;âge moyenne 28,9 a.).En tout cas il faut considérer qu'en même temps la prevalence des sujets positives à l'HIV parmi les donneurs de sang du Centre de Transfusion a été le 0,4%,quinze fois inferieur avec une différence statistiquement très significative.
Conclusion. Notre hypothèse paraîtrait confirmée et donc nous croyons qu'il faudra structurer des spécifiques programmes d'éducation sanitaire pour ces patients.

W.B.P.207 ETUDE DE LA DEMANDE PSYCHOTHERAPEUTIQUE CHEZ 100 PATIENTS ATTEINTS DE SIDA.

Yves EDEL, O. OUVRY, médecins psychiatres
F. ROGNIER-AEBERHARD, M. MARCHAND-GONOD, J. RODRIGUEZ, psychologues.
Département des Maladies Parasitaires et Infectieuses, et Santé Publique, Unité INSERM 313 (Pr M. Gentilini), Groupe Hospitalier Pitié-Salpêtrière, Paris, France.

L'étude d'un groupe de cent patients séropositifs symptomatiques non SIDA ou SIDA avéré a été menée par l'équipe médico-psychologique mise en place dans le Service du Pr M. Gentilini en 1983 pour l'accompagnement psychologique et psychiatrique des malades atteints par le VIH.

A partir d'entretiens individuels semi-directifs et d'un questionnaire d'évaluation (111 items), les auteurs donnent les résultats d'une approche épidémiologique du retentissement psycho-pathologique de l'infection à VIH dans ses corrélations avec la demande de soutien psychologique, les antécédents psychiatriques personnels, les facteurs familiaux et de l'environnement.

Dans le cadre de cette première étude dans un service hospitalo-universitaire, il ressort que :

- 62 % des patients ont demandé un soutien psychologique durant le temps d'hospitalisation ; 23 % ont refusé toute intervention psychologique spécialisée ; 24 % ont demandé une psychothérapie de soutien (brève ou longue) après l'hospitalisation.
- 18 % des homosexuels, 50 % des toxicomanes, sous-groupes étudiés, avaient des affections psychiatriques précédant l'infection par le VIH.

Les facteurs influençant le non-dit de la séropositivité, de la toxicomanie, de la sexualité sont corrélés à la relation d'aide de l'entourage (famille).

W.B.P.208 CLASSIFICATION DES TROUBLES PSYCHIATRIQUES SELON LE DSM III°-r EN COURS DE SIDA

Zamperetti Marco*;Schlacht I.**;Ferrazzi D.**
*Servizio Psichiatrico di Diagnosi e Cura "Origgi I°" e Centro di Medicina Comportamentale (Responsabile Prof.G.F. Goldwurm); **Reparto Infettivi Adulti (Responsabile Prof.F. Ciannelli); Ospedale Cà Granda Niguarda,Milano,ITALY.

Objectif. En considération de la frequence élevée des troubles psychiatriques,soit primaires que secondaires,en cours d'infection de HIV il nous a paru utile classer ces communs complications de cette pathologie.
Méthodes. Pour cet étude nous avons pris en considération les patients hospitalisés depuis deux ans dans notre hôpital en maladies infectieuses à cause de l'HIV et dans lesquels ont apparu,outre les symptômes physiques,des troubles psychiques; nous avons aussi consideré ceux qui ont été hospitalisés en psychiatrie et dans lesquels on a trouvé une positivité à l'HIV asymptômatique du point de vue somatique. Les diagnostics ont été posés selon les principes du DSM III°-r.
Résultats. Nous avons considéré 79 sujets avec infection d'HIV à différents stades et aussi avec des troubles (t.)psychiques. Les mâles étaient le 74,7 %(59/79) et les femelles le 25,3 %(20/79); l'âge moyen était 29,5 a. Les facteurs de risque ont resultés être: la toxicomanie 65,8 %(52/79); l'homosexualité 22,8 %(18/79); les rapports hétérosexuels 8,9 %(7/79); les transfusions 2,5 % (2/79). Les diagnostics psychiatriques ont été: t.mentaux organiques 29,1 %(23/79); t. de l'humeur 22,8 %(18/79); t. de l'adaptation 17,7 %(14/79); t.de la personnalité 11,4 %(9/79); schizophrénie 7,6 %(6/79); t. d'anxiété 6,3 %(5/79); psycotiques pas classés ailleurs 5,1 %(4/79).
Conclusions. On confirme la prévalence élevée des t. mentaux organiques mais il nous semble aussi interessant la considerable presence des t. psychiatriques en strict sens comme la schizophrénie.

W.B.P.209 HIV SEROPREVALENCE STUDY OF INVOLUNTARILY HOSPITALIZED MENTALLY ILL HOMELESS FROM THE STREETS OF MANHATTAN, NEW YORK

Empfield Maureen*,Weinstock A*,Cournos F**,Schrage H*,
Meyer I*,Schoenbaum E***, et al *Creedmoor Psychiatric Center,Queens,NY ** Psychiatric Inst,NYC***Montefiore Med.Ctr.,Bronx,NY USA

Objectives: To determine the rate of HIV seroprevalence and risk taking behavior among a group of high risk psychiatric patients, i.e., the homeless mentally ill who shun health care services and are involuntarily hospitalized by mental health teams in New York City.
Methods: The study is conducted on The Creedmoor Psychiatric Center Intensive Placement Unit, which is part of New York City's largest state hospital. Homeless mentally ill patients removed from the streets are accepted for intermediate care and placement. This population tends to avoid public shelters and is demographically diverse. 28% are female and 72% are male. Ethnically, 46% are white, 39% are black, 13% are hispanic and 2% are Asian. All ages between 18 and 65 plus are well represented. There is a high rate of medical illness including active TB, positive VDRL and hepatitis B antibodies. Approximately 30% of patients abuse substances. Anonymous bloods will be tested for HIV antibodies on approximately 100 patients and correlated with histories of risk taking behaviors including needle sharing, prostitution and sexual behavior. These findings will also be correlated with geographic mobility, patterns of homelessness and psychiatric and medical illnesses.
Results: To be presented at the conference.

W.B.P.210 PSYCHIATRIC DIAGNOSES AMONG VOLUNTEERS FOR HIV TESTING

Jacobsberg,Lawrence; Perry, S; Fishman, B; Frances, A; Ryan, J; Fogal, K. Cornell Medical Center, New York, NY

Objective: The determine the rates of DSM-III-R diagnoses among individuals volunteering for HIV serological testing.
Methods: We administered the Structured Clinical Interview for DSM-III-R (for Axis I) and the Personality Disorders Examination (for Axis II) one week prior to HIV serological testing to a heterogeneous population of 231 physically asymptomatic adults at perceived risk for AIDS who had enrolled in a prospective psychobehavioral study.
Results: Overall rates for the presence of any Axis I disorder were 25.5% current and 64.1% lifetime; for Axis II disorders the overall rate was 28.6%. Compared to reported community samples, these subjects had high rates of mood disorders, both current (13.9%) and lifetime (42.9%). Lifetime rates of non-alcohol substance dependence were also high (30.3%), even after eliminating from analysis the 21 subjects with intravenous drug use as a risk factor. An Axis II personality disorder was present in 50.8% of subjects with a current Axis I diagnosis and in 35.8% of those with a lifetime Axis I diagnosis. Conversely, most subjects (53.6%) with an Axis II diagnosis met criteria for a current Axis I disorder and almost all (94.6%) met criteria for a lifetime Axis I disorder.
Conclusion: A large subgroup of the volunteers for testing had histories of depression and non-alcohol substance dependence. A substantial subpopulation with Axis I psychopathology may have additional treatment needs posed by Axis II disorders.

W.B.P.211 PSYCHIATRIC DIAGNOSES AND TREATMENT OUTCOME IN AN AIDS SPECIALTY CENTER

Havens, Jennifer; Finkelstein, E.; Viederman, M.; Jacobs, J. New York Hospital-Cornell Medical Center, New York, New York, USA

Objective. We examined baseline patterns of psychiatric referrals, psychiatric diagnosis and treatment outcome in a cohort of PWA's in an AIDS specialty center. Methods. Twenty-eight patients were referred for psychiatric evaluation and treatment in a six month period. This number represents 50% of inpatient admissions and 25% of outpatients followed by the center. Risk factors for HIV infection in the referred population were: 57% IVDA, 36% homosexual contact and 7% heterosexual contact. Results. The most prevalent psychiatric diagnoses in the outpatient setting were major depression (44%) and organic brain syndromes (25%). In both groups there was good response to psychotropic medications, with 80% of depressed patients improving on tricyclic antidepressants and 75% of OBS patients improving on neuroleptics and other agents. The most prevalent psychiatric diagnoses in the inpatient setting were organic brain syndromes (50%), ongoing drug addiction (22%) and major depression (17%). Both OBS and major depression were responsive to psychopharmacological treatment in greater than 75% of cases. In both inpatients and outpatients, psychiatric treatment was not successful in halting ongoing drug abuse. Nevertheless, psychiatric consultation was helpful in establishing realistic treatment goals in both settings. Conclusion. In this pilot study, high baseline rates of psychiatric illness were found in an AIDS specialty center. Psychiatric evaluation and psychopharmacologic treatment resulted in symptomatic improvement in those patients suffering with major depression and organic brain syndromes. We conclude that psychiatric treatment and evaluation is an essential feature of the comprehensive care of PWA's in the AIDS specialty clinic.

W.B.P.212 PSYCHOSOCIAL STATUS OF 192 PATIENTS WITH HIV INFECTION AND AIDS

King, Michael, B.
Institute of Psychiatry, De Crespigny Park, London SE5, U.K.

Objective. Before planning psychological services for patients infected with HIV, we need epidemiological data on immediate and long-term psychological consequences of the diagnosis.

Methods. HIV positive outpatients were interviewed in a standardised manner at the HIV clinics of 2 London hospitals.

Results. 192 patients took part: 65 were HIV positive but well, 64 had accompanying symptoms or signs (41 PGL, 23 ARC) and 63 had AIDS. Almost all had revealed their diagnosis to others, 25% receiving negative reactions. 31% had a psychiatric disorder, half of whom reported emotional problems prior to HIV infection. Patients with ARC or those diagnosed less than a year ago tended to have more psychological symptoms. 22% complained of impaired memory or concentration, of whom more than half had cognitive impairment on brief assessment. Extreme health worries predicted wider psychological problems.

Conclusion. This degree of psychological distress is similar to reports for patients with other medical conditions. Subjects with past psychological difficulties and those who worried excessively about their health were more likely to be psychiatrically disturbed. Overall, patients had adapted well, despite the stigma and poor prognosis of their disorder.

W.B.P.213 ANALYSIS OF INITIAL PSYCHIATRIC REFERRALS FROM A HOSPITAL HIV SERVICE

DiGiovanni, Cleto* **; Goyer, P.F.*
*National Naval Medical Center, Bethesda, Maryland, USA, **The Johns Hopkins Hospital, Baltimore, Maryland, USA.

Objective. To determine patterns of initial utilisation of psychiatric services by a hospital HIV program.
Methods. We reviewed 396 admissions to a military hospital's HIV service made by 354 patients over a 12-month period to determine the nature of initial requests for psychiatric consultation.
Results. Nearly 14% of the admissions required psychiatric consultation; that percentage applied equally to newly identified HIV seropositive persons undergoing initial medical evaluation and to persons who had been previously diagnosed, educated about their infection, and counseled and were now admitted for periodic medical reevaluation or treatment. Psychiatric services were especially in demand when patients learned they were antibody positive, began to note early evidence of disease progression, or were in late stages of illness. In order of decreasing frequency, psychiatric diagnoses were adjustment disorders, major affective disorders, substance abuse, and delirium or other organic brain disorders (excluding dementia).
Conclusion. In a setting of free, readily available medical and psychosocial care, nearly 14% of patient admissions required referral to a psychiatrist rather than to other mental health therapists. Similar studies from other medical centers could yield data that might help mental health planners prepare their resources for the still unfolding HIV epidemic.

W.B.P.214 A COMPARISON OF SUICIDAL BEHAVIORS IN PATIENTS IN AN AIDS RELATED PSYCHIATRIC CLINIC AND IN A GENERAL PSYCHIATRY CLINIC

O'Dowd,Mary, McKegney, FP, Natali, C, Markavy, J,and Asnis,G:
Montefiore Med.Center,Albert Einstein College of Medicine,Bronx,New York USA

Objective.To assess the extent of suicidal behaviors in a population of AIDS, ARC and HIV positive patients.
Methods.69 patients attending a psychiatric outpatient clinic for HIV related problems were surveyed as to past or present suicidal behaviors, and compared to a demographically matched sample of patients attending a general psychiatry outpatient clinic. Both populations were predominantly Hispanic (60%)with almost equal numbers of men and women. Major risk factors for the HIV clinic group were IVDA (52%), heterosexual sex partner of person at risk(22%), homosexuality (22%) and none (6%). HIV related diagnoses were:AIDS n=23; ARC n=9, asymptomatic HIV+ n=14; HIV- n=8; unknown serology, n=15.
Results. There were no significant differences in the incidence of suicidal behaviors between patients attending the two clinics. Within the HIV clinic population there were no significant differences in the incidence of suicidal behaviors by diagnosis of AIDS,ARC,HIV+,HIV-, or unknown serology.There were no significant differences in psychiatric diagnoses among the AIDS diagnosis groups. For each of the AIDS diagnosis groups, the mean age of the first suicidal attempt antedated clinic enrollment:AIDS 7yrs; ARC 17 yrs; HIV+ 14 yrs; HIV-13 yrs, thus preceeding the diagnosis of AIDS or HIV+ for most patients.
Conclusions. HIV related disease status was not associated with increased suicidal ideation or attempts in the surveyed population. There were no differences in the incidence of suicidal behaviors between the HIV related psychiatric clinic population and an age and ethnicity matched general psychiatric outpatient population.

W.B.P.215 PSYCHIATRIC HISTORY AMONG HOMOSEXUALS AND DRUG-ADDICTS INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS

Gala , Costanzo *; Martini, S. *; Pergami, A.*; Rossini, M.*; Russo, R. *; Lazzarin , A. ** .
* Institute of Psychiatry , ** Institute of Infectious Diseases, University of Milan, Italy.

Objective: to evaluate psychiatric history among HIV-infected subjects (homosexuals,drug-addicts and heterosexuals).
Methods: 218 subjects HIV-infected (II,III C.D.C.) , 60 subjects at risk of HIV infection seronegative for antibody to HIV , 50 healthy heterosexual controls were recruited from the Dpt. of Infectious Diseases. We examined each subject with a psychiatric interview in order to collect: 1) previous personal and familial psychopathological history (considered in terms of lifetime prevalence); 2) Early Life Losses (E.L.L.); 3) Attempted Suicides (A.S.).
Results: a lifetime prevalence of personal and familial psychiatric disorder was higher in Seropositive (S+) (15%,22%) and Seronegative (S-)(27%,24%) subjects than in the Control Group(C.G.).43% of S+,41% of S-,1,5% of C.G. reported E.L.L. . The prevalence of A.S. was 22% (S+),17%(S-) & only 0.2(C.G.).
Conclusion: 1) psychiatry morbidity among S+ was higher before the onset of HIV-infection , 2) awareness of psychiatric history is important for the monitoring and management of S- at risk of HIV-infection.

W.B.P.216 A COMPARISON OF PSYCHIATRIC CONSULTATIONS IN AIDS AND NON AIDS PATIENTS

O'Dowd, Mary Alice, McKegney, FP, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, New York USA.

Objective. To identify differences between AIDS patients and age matched medical patients without AIDS seen in psychiatric consultation on the medical service of a large voluntary general hospital.
Method. All psychiatric consultations done in one year on the acute medical service of a large voluntary hospital were reviewed, comparing AIDS patients (n=67) with other medical patients without AIDS (n=121) under age 55.
Results. There were significant differences between the two groups of consultation patients in ethnicity(AIDS patients more often Hispanic and less often Caucasian $p<01$). The AIDS group was predominantly male (69%) while the non-AIDS group was predominantly female(68%),a difference significant at $p<001$. There were no significant differences between the AIDS and non-AIDS groups in the incidence of diagnosis of depression, suicidal risk, substance abuse, or adjustment disorder. An Axis II diagnosis was made significantly less often in the AIDS group ($p<05$). The incidence of organic mental disorder was significantly higher in the AIDS group ($p<05$).Staff spent an average of 4.0 hours on AIDS consultations compared to 3.4 hours on non-AIDS consultations. There were 26 repeat consultations (40%) requested for the 67 AIDS patients, compared to 17 repeat consultations (12%)in the 121 non-AIDS patients.($p<.01$).
Conclusions. With the exceptions of OMS and Axis II diagnoses, there were no significant differences in psychiatric diagnoses between AIDS patients and non-AIDS patients seen in psychiatric consultation. AIDS patients required more staff consultation time and repeat consultations, thus creating a heavier time burden on psychiatric services.

W.B.P.217 ESTABLISHMENT OF AN HIV RELATED PSYCHIATRIC CLINIC IN AN AREA OF HIGH SUBSTANCE ABUSE.

O'Dowd,Mary Alice, Natali, C, and McKegney, FP, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, New York USA.

Objective. To describe an innovative psychiatric outpatient clinic for HIV related care and to identify factors related to patient drop out.
Method. A psychiatric outpatient program was established in an area with a high rate of HIV infection among Hispanic and black intravenous drug users (IVDU) and their sexual partners. The only criteria for admission was a need for psychiatric services due to HIV,irrespective of serology. Strategies to enhance patient retention included flexible scheduling, vigorous outreach and Spanish speaking staff. Data on all patients was reviewed after one year to identify differences between those successfully enrolled versus dropouts.
Results. 148 patients were seen, equally divided between men and women. 60% were Hispanic. 53% gave IVDU as the primary risk factor, followed by heterosexual transmission 23%. 30% had AIDS, 14% ARC, 26% HIV+ asymptomatic, and 12% known HIV-. 41% had a history of prior psychiatric inpatient or outpatient care. The most common psychiatric diagnosis was adjustment disorder 62%, followed by any substance abuse disorder 47%. Organic mental syndromes were diagnosed in 6%.Those who dropped out of treatment(48%)were more likely to be on methadone, abusing alcohol, and have a diagnosis of organic mental syndrome and less likely to have a diagnosis of adjustment disorder.There was no difference in incidence of prior psychiatric treatment.
Conclusions. HIV related psychiatric services can be delivered to a minority population in an area of high substance abuse reaching many individuals without prior mental health services. On-going substance abuse and organic mental syndromes make successful enrollment less likely.

W.B.P.219 LOCUS OF CONTROL, SOCIAL SUPPORTS AND DEPRESSION AMONG HIV INFECTED SUBJECTS

Gala Costanzo; Martini,S.; Pergami, A.; Rossini, M.; Russo, R.; Durbano, F.
University of Milan, Medical School, Dept. of Psychiatry, Italy.

Objective. To evaluate the relationship among Social Supports, External-Internal Coping and psychopathological responses in subjects infected with Human Immunodeficiency Virus.
Methods. 125 subjects HIV infected (65 drug-addicts, 43 homosexuals, 17 heterosexuals) in CDC groups 2-3 were administered: 1) I-E Locus of Control; 2) Availability of Social Supports; 3) Zung Anxiety and Depression Scales.
Results. Social Supports have no influence on psychopatological responses. External subjects are more anxious and depressed than Internal ones.Internal subjects with grater availability of Social Supports have lower depression scores.
Conclusions. Availability of Social Supports does not reduce psychopathological responses in our total sample, but Internal subjects seem to benefit by a greater availability of Social Supports. On the other hand External subjects showing a greater psychopathological response do not benefit by available Social Supports. These subjects are in greater need of counselling.

Psychiatrie/Études de prévalence
Psychiatry/Provalence Studies

W.B.P.221 HANDEDNESS AND IMMUNE SYSTEM FUNCTION IN GAY/BISEXUAL MEN: The Multicenter AIDS Cohort Study (MACS).

James T. Becker, L. Kingsley, S. Bass, P. Satz, M.A. Dew, L. Penkower, O. Selnes, K. Sheridan. Depts. Psychiatry, Neurology & Epidemiology, Univ. Pittsburgh, Johns Hopkins Med. Inst., UCLA & Northwestern Univ., U.S.A.
OBJECTIVES: The purpose of the present study was to evaluate the relationships between handedness and immune system function in gay/bisexual men. Two hypotheses were tested: 1)gay/bisexual men are more likely to be left-handed; 2)left-handers are more likely to show impaired immune function.
METHODS: Sixteen hundred and five MACS participants completed a five-item version of the Edinburgh handedness inventory as part of a study of the neuropsychiatric manifestations of HIV-1 infection.
RESULTS: Among HIV-1 seronegative men there was a doubling of the rate of exclusive lefthandedness (6.7% vs. 3.1%), a decrease in exclusive right-handedness (58.3% vs. 62.0%), and no difference in the rates of self-reported mixed handedness (34.9% for both samples) when compared to males in the general population (General Cincinnati Survey). This difference was significant (p .001), although the effect size was small (phi=.12).

Handedness was not associated with either prevalent or incident HIV-1 serostatus. Neither were left-handers more likely to develop either AIDS or severe depletion of CD4 cells (200) than other men.
CONCLUSIONS: These data replicate earlier findings of increased left-handedness among gay/bisexual men; however, there was a lack of association between handedness and immune system function. Thus, while there may be a small increase in left-handedness among gay men, the basis for this increase is not known, and handedness has no impact on clinical illness.

W.B.P.218 EFFECT OF NEUROPSYCHIATRIC SIGNS AND SYMPTOMS ON HOMELESS PERSONS WITH AIDS IN A GROUP RESIDENCE

Staats, JoAnne; Hough, G. and Dornan, D.
AIDS RESOURCE CENTER, New York, U.S.A.

Objective. To assess and manage HIV neuropsychiatric impairment in persons living in a residence for homeless persons with AIDS.
Methods. Consecutive admissions (N=120) to Bailey House, a residence for 44 homeless persons with AIDS in New York City, were evaluated by a nurse-practitioner for psychiatric symptoms as a part of general history and physical examination at admission. Pre-morbid symptoms were documented - e.g., history of stroke, substance abuse or psychiatric care--and to identify HIV related impairments. Signs and symptoms were monitored in weekly nursing contacts.
Results. Thirty per cent of residents (N=37) reported bothersome, chronic early symptoms of AIDS-related dementia (e.g., memory loss) for which they had devised their own coping mechanisms (e.g., systems of reminders). Twenty per cent (N=25) presented signs and symptoms; personality changes, progression of memory loss, lower extremity weakness and pain, impaired vision, and incontinence. In 55 per cent of the residents (N=65) other psychiatric and CNS problems were encountered that were documented prior to HIV infection. These included personality disorders, psychosis, depression, drug and alcohol abuse, and medical conditions. These individuals often suffered refloresence of pre-existing problems while living at Bailey House. In the 20 per cent of residents with more severe problems, inability to cope appeared to be related to the existence, severity, and frequency of requried higher elvels of pre-morbid CNS and psychiatric problems. Those with more severe pre-morbid problems required higher levels of intervention and on occasion (N=6) referral to medical or psychiatric hospitalizations and/or intercurrent cocaine abuse. Interventions will be described.
Conclusion. Persons with AIDS suffering from neuropsychiatric impairment can function in a residential setting. Periodic monitoring of symptoms is helpful in planning interventions.

W.B.P.220 FREQUENCY OF PSYCHIATRIC DISORDERS IN HOSPITALIZED AIDS PATIENTS: COMPARISON TO A GENERAL HOSPITAL POPULATION

Schaerf, Frederick W., Koenig, T., Wisner-Carlson, R, The Johns Hopkins Hospital, Baltimore, Maryland, USA

Objective: To report results of psychiatric consultations on hospitalized AIDS patients and compare prevalences of diagnoses to those from general hospital consultations.
Methods: Eighty-five consecutive consultations (mean age 33) from the inpatient AIDS unit were compared to 85 consecutive general hospital (GH) consults (mean age 52) and 40 consecutive age and sex matched GH consults (mean age 36). Patients were evaluated by a psychiatrist and diagnoses made according to DSM-IIIR criteria. Data were compared using CHI-Square analysis.
Results: The table lists the 4 most frequent diagnoses in the AIDS group and percentages of total diagnoses as compared to the other two populations.

	AIDS	GENERAL		AGE/SEX MATCHED	
1. Adjustment disorder	34%	23%	p<0.002*	23%	p<0.005**
2. Delirium	30%	16%	p<0.001*	17.5%	p<0.001**
3. Dementia	14%	6%	p<0.001*	0%	p<0.001**
4. Major depression	7%	27%	p<0.001*	13%	N.S.**

*AIDS VS GENERAL,**AIDS VS AGE/SEX MATCHED

Conclusions: Adjustment disorder predominates in the AIDS consult population, undoubtedly related to the chronic, deteriorating course of the disease. That delirium and dementia are twice as prevalent in this group and that the latter diagnosis was not found at all in an age-matched population suggests that consult-liaison psychiatrists and primary physicians must be especially aware that AIDS patients are quite susceptible to alterations in consciousness and cognition.

W.B.P.222 PSYCHONEUROIMMUNOLOGIC STUDIES OF GAY MEN WITH HIV INFECTION

Gorman, Jack M.; Williams J.; Stern Y.; Mayeux R.; Goetz,R.; Kertzner,-R.; et. al. HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, New York, N.Y. U.S.A.

In order to explore possible relationships between psychiatric and neurological morbidity with medical and immunological status in patients with HIV infection, we began a five year follow-up study in October, 1987. At present, 196 gay men have been seen at least one time, 118 of whom were HIV seropositive at the time of study entry. The HIV positive and negative men are well-matched for age, ethnicity, and economic status. We devised a medical staging system for seropositive subjects ranging from "0" representing no medical symptoms or signs to "39" representing advanced AIDS. The mean medical staging score at study entry was 13.5, representing only minimal medical signs of HIV infection. Seropositive subjects had significantly lower ratio of T4 to T8 lymphocytes, lower absolute T4 count, and higher T8 count than seronegative subjects. Nineteen seropositive subjects but none of 73 seronegative subjects were positive for presence of p24 antigen in blood. Among the 118 seropositive subjects, T4/T8 ratio correlated significantly with medical stage (r=-0.21, p=0.02) and presence of p24 antigen (r=-0.20, p=0.03). In this group of relatively asymptomatic HIV seropositive subjects, there was relatively little psychiatric, neurologic and neuropsychologic morbidity. Consequently, at study entry there are no significant correlations between medical stage or immunologic status and nervous system pathology.

W.B.P.223 PSYCHIATRIC DISORDER AND HIV INFECTION: A CONTROLLED, LONGITUDINAL STUDY

Atkinson, Hampton*; Grant, I.*; Heaton, R.*; Weinrich, J.*; McCutchan, J.*
*Univ. of California, San Diego, CA, USA

Objective. To examine the prevalence of psychiatric disorder in various stages of HIV infection. We recently reported elevated lifetime prevalences of psychiatric disorder in HIV illness, and noted that onset of selected psychiatric disorders often preceded the AIDS pandemic, suggesting that some individuals might be at increased vulnerability for later disorder. Here we report on a larger cohort and include preliminary one-year follow up. Methods. Subjects were 135 homosexual (high risk) and 22 heterosexual (low risk) men who were examined with the Diagnostic Interview Schedule (DIS). Results. The table gives the most prevalent lifetime diagnoses.

Diagnosis	CDC IV (N = 37)	CDC II/III (N = 62)	HIV - (N = 36)	Heterosexuals (N = 22)
Maj. depression	32%	31%	31%	9%
Gen. anxiety	32%	34%	39%	0
Alcohol	35%	31%	41%	36%

Six month rates did not differ across high risk groups but exceeded low risk rates. Alcohol use disorders and over 20% of affective disorders preceded documentation of serostatus. One year follow up (N = 26 to date) incidence of major depression was 8%; gen. anxiety 23%; and alcohol disorder 4%. Conclusion. Careful assessment of high risk men, regardless of serostatus, may be warranted for selected psychiatric disorders.

W.B.P.224 NEUROPSYCHOLOGICAL AND PSYCHOSOCIAL FUNCTION IN TWO COHORTS OF GAY MEN: RELATION TO STAGE OF HIV-1 INFECTION

Andrew J Saykin*, R Janssen**, G Sprehn*, T Spira**, L Cannon***, J Kaplan**, B O'Connor*, S Watson***, R Allen*** et al.
*** University of Pennsylvania, Philadelphia; ** Centers for Disease Control, Atlanta *** Department of Public Health, San Francisco, USA.

OBJECTIVE: To characterize neuropsychological function, affective status and changes in activities of daily living in relation to stage of HIV infection. METHODS: Eighty-five HIV-1 seropositive gay men enrolled in prospective studies in Atlanta, GA, and San Francisco, CA, [Asymptomatic (ASX=35); Generalized Lymphadenopathy (GL=18); AIDS-Related Complex (ARC=32)], and 75 seronegative (SN) matched gay controls were evaluated with neuropsychological testing, the MMPI-168, other affective measures and an 82-item Activities of Daily Living Scale (ADL-82).
RESULTS: Data were analyzed by MANOVA with stage of HIV-1 infection as the grouping factor. For ADL, the ARC group rated themselves as more disabled than controls on 6/12 scales: Attention/Planning, Memory, Language/Reading, Self-care, Motor, and Sexual Functions (p=.0013). On the MMPI-168, the ARC group showed more somatic complaints, depression, anxiety and social withdrawal than controls (p=.0061). Neuropsychological function was impaired in ARC subjects relative to controls for verbal cognition and verbal and visual memory (p=.0226). The ASX and GL groups did not differ from controls on any ADL, MMPI-168 or neuropsychological scale.
CONCLUSION: Neuropsychologic dysfunction, affective complaints and self-reported disability were associated with ARC, but not ASX and GL.

W.B.P.225 THE EFFECT OF HIV ANTIBODY STATUS ON U.S. MILITARY APPLICANT APTITUDE TEST SCORES

Arday, David R.*; Brundage, J. F.*; Gardner, L. I.*; Goldenbaum, M.*; Wann, F.*; Wright, S.**. *Walter Reed Army Institute of Research, Washington, DC, USA. **US Military Entrance Processing Command, North Chicago, IL, USA.

Objective. To estimate the effect of HIV-1 seropositivity on Armed Services Vocational Aptitude Battery (ASVAB) test scores in otherwise healthy individuals with early HIV infection. Methods. The ASVAB is a ten test written multiple aptitude battery, administered to all military enlisted applicants. Since 1 Oct 85, all recruit applicants have been serologicly tested for antibodies to HIV-1. A total 975,489 induction testing records containing both ASVAB and HIV results from Oct 85 through Mar 87 was obtained. An analysis data set (N=7698) was constructed by choosing 5 controls for each of the 1283 HIV+ cases, matching on 5-digit zip code, and a multiple linear regression analysis was performed to control for demographic and other factors which might influence test scores. The model developed is sensitive enough to detect an HIV effect of roughly 0.06 standard deviation (SD) in ASVAB scores.
Results. Years of education and ethnicity were the strongest predictors of test scores. The HIV+ effect on an ASVAB composite score was -0.09 SD (99% CI = -0.17, -0.02), while the effect on the separate test scores ranged between -0.39 and +0.06 SD, with corresponding R^2 values from .41 to .09. The two ASVAB component tests felt *a priori* to be the most sensitive to HIV+ status (coding speed and numerical operations) showed the least decrease with seropositivity. The auto/shop knowledge component showed the greatest HIV status effect.
Conclusion. While very sensitive, this model appears to show little evidence of a strong HIV effect upon military enlisted applicant test scores. The low R^2 values imply that most variability in test scores is due to neither demographic factors nor HIV status.

W.B.P.226 A LONGITUDINAL ANALYSIS OF PERCEPTION OF PHYSICAL HEALTH AND SYMPTOMS OF DEPRESSION IN GAY/BISEXUAL MEN: The Multicenter AIDS Cohort Study (MACS).

James T. Becker, S. Zeger, M.A. Dew, R. Karim, L. Kingsley, P. Satz, F.W. Schaerf, K. Sheridan. Depts. Psychiatry, Neurology & Epidemiology, Univ. Pittsburgh, Johns Hopkins Med. Inst., UCLA, Northwestern University, U.S.A.

OBJECTIVES: The perception of symptoms of impaired physical health, specifically lymphadenopathy syndrome (LAS) has been associated with elevated scores on the Center for Epidemiological Studies- Depression scale (CES-D). The purpose of this study was to evaluate the change in this relationship during a four year follow-up period.
METHODS: Each participant in the MACS Completed the CES-D at the time of their regular clinic visits. They were classified in terms of self-perception of LAS and clinically identified LAS at each visit.
RESULTS: Those men who perceived LAS had significantly elevated CES-D scores compared with men who did not share this perception. Furthermore, the proportion of men with clinically abnormal scores was greater among those who perceived that they had LAS. These relationships were stable over time, and the men who reported LAS in the face of a normal clinical examination were relatively unchanged after two years. Similar relationships were found when oral thrush was examined (i.e., perceived vs. observed).
CONCLUSIONS: These data are consistent with a large body of evidence concerning the relationship between perceived physical well being and mood. They suggest that even as men become more educated about HIV-1 infection, and have more experience with their own symptomatology, the impact of perceived abnormalities remains the same.

W.B.P.227 NEUROPSYCHIATRIC FEATURES OF AIDS: A COMPARISON WITH MULTIPLE SCLEROSIS

Morriss, R.*, Schaerf, Frederick W., Brandt, J., McArthur, J., Folstein, M. Department of Psychiatry, Leeds University, Leeds, U.K.* and Departments of Psychiatry and Neurology, Johns Hopkins Hospital, Baltimore, MD, USA

Objective: To compare rates of psychiatric disorders and cognitive functioning in outpatients with AIDS and ambulatory patients with Multiple Sclerosis (MS).
Methods: Twenty gay male AIDS outpatients, 20 gay male HIV-1 seronegative volunteers and 20 MS outpatients (steroid free) received a structured psychiatric interview (PSE) and a neuropsychological screening battery. Groups were matched for age, sex and disability and data analyzed with NOVA. Chi-square was used to examine nominal data.
Results: AIDS patients had significantly more current psychiatric disorders than MS or HIV seronegative patients (X2=8.29, d.f.=1, p<0.005). Anxiety disorders occurred significantly more often in AIDS patients than MS or HIV seronegatives (X2=3.96, d.f. = 1, p<0.005). Cognitively, MS patients performed significantly worse than AIDS patients who did worse than HIV-1 seronegatives on Trailmaking A and Symbol Digit Modalities (F=5.62, d.f.=2, p<0.01).
Conclusion: In these samples, outpatients with AIDS had rates of psychiatric disorder that exceeded those of patients at risk for HIV infection or those with MS., However, Multiple Sclerosis patients perform worse than AIDS patients on Trails A and Symbol Digit Modalities. Future studies of AIDS patients must therefore determine the origin and treatment of psychiatric disorders when examining cognitive status and neuropsychological performance.

W.B.P.228 PSYCHIATRIC FINDINGS IN HIV-SEROPOSITIVE PERSONS IN A MANDATORY HIV SCREENING PROGRAM

Rundell James*; Brown G.**; and Paolucci S.**.
*Uniformed Services University of the Health Sciences, Bethesda, Maryland, USA; **Wilford Hall USAF Medical Center, San Antonio, Texas, USA.

Objective. To determine the frequency of psychiatric diagnoses and degree of psychological distress in persons found to be HIV-infected in the U.S. military's mandatory HIV screening program. Methods. 95 randomly selected HIV-infected military personnel were examined by board-certified psychiatrists.
Results. The most frequent psychiatric diagnoses were: simple phobia (18.9%), adjustment disorder (17.9%), hypoactive sexual desire disorder (12.6%), alcohol abuse (9.5%), major depression (5.4%), organic mental disorders (5.4%), psychological factors affecting physical condition (5.4%), and panic disorder (2.1%). Psychiatric rating scale results are: Michigan Alcoholism Screening Test score ≥ 5 (20.0%); Hamilton Anxiety Scale scores ≥ 12 (15.8%) and ≥ 16 (7.4%); Hamilton Depression Scale scores > 12 (18.9%) and ≥ 16 (5.3%). 21.1% admitted to current suicidal thoughts; 2 patients had a recent suicide attempt.
Conclusion. Minor forms of psychopathology, dysphoria, anxiety, and suicidal ideation are common in persons who learn they are HIV-infected in a mandatory HIV screening program. Major psychiatric illness is less frequent but present in an important number of individuals.

W.B.P.229 AUDITORY EVENT RELATED POTENTIALS (ERPs) IN THE CLINICAL EXAMINATION OF HIV INFECTED DRUG USERS.

*Chiswick A, *Egan V, ~Goodwin GM, ~St Clair D, *Brettle RP.
*City Hospital; ~Royal Edinburgh Hospital; EDINBURGH, EH10, SCOTLAND.
UNITED KINGDOM

OBJECTIVE: Slowing of the long latency ERP occurring some 300 msec. post stimulus has been detected in patients suffering from Alzheimer's disease. A prospective study of the ERPs of HIV infected Injection Drug Users (IDUs) was undertaken to detect the onset of HIV related dementia.
METHOD: 322 HIV infected patients have been assessed at the Infectious Diseases Unit of the City Hospital, Edinburgh. 253 (79%) were infected between 1983-85 by IDU. 138 of this group were recruited into a prospective study of ERPs, using a two tone auditory paradigm. 30 patients have been retested at intervals of 6-12 months.
RESULTS: Mean P300 for the sample was 320 msec. (SD = 30), significantly slower than 212 normal controls (mean = 301, SD = 22.6) t = 5.92; p < 0.005. No significant differences were shown between current injection users, oral users and ex-users. Furthermore, no significant difference was shown by cross-sectional comparison across CDC status for any latency component of the ERP. No patient has yet developed dementia.
CONCLUSION: Despite considerable drug use, ERP results were readily obtained and interpreted. Significant slowing of ERPs of the IDU group was noted, but serial measurements are required during the course of HIV infection to relate change to neuropsychiatric or other clinical development.

W.B.P.231 PRELIMINARY FINDINGS ON A SCREENING SYMPTOM CHECKLIST FOR HIV DEMENTIA

Boccellari, A.; Dilley, James W.; Davis, A.; Moss, A.; Bacchetti, P.; Wagner, B.
San Francisco General Hospital, University of California San Francisco School of Medicine, Dept. of Psychiatry and UCSF AIDS Health Project, San Francisco, California, U.S.A.

Objective. To describe the development of a screening self-report symptom checklist to detect individuals at risk for the development of HIV Related Dementia.

Methods. Seventy-nine subjects (56 HIV+ and 23 HIV- Controls) completed a 55 item checklist of HIV Related CNS symptoms. Subjects were also given a battery of neuropsychological tests (NP) and psychiatric rating scales. Measures of immune functioning were also obtained. The HIV Dementia Symptom Checklist (HDSC) documents the presence and severity of self-report prodromal physical symptoms and neurological/neurobehavioral changes.

Results. Cronbach's alpha (α = 0.96) was calculated to estimate the internal consistency of the scale. Furthermore, the total score on the HDSC was shown to have a low but significant correlation with numbers of Helper T-Cells (CD_4 r = - 0.20, p<.05). The score also correlated with impairment on NP testing, particularly on measures of verbal memory (r = -.27, p<.01), visual-spatial memory (r = - 0.31, p<.01), fine motor speed (r = - 0.24, p<.05), speeded mental operations (r = 0.36, p<.001), and sustained concentration (r = 0.43, p<.001). While no significant differences between the groups on measures of depression and anxiety were found, the HDSC significantly differentiated the HIV+ group from the HIV- controls (p = <.001), on both the prodromal physical symptoms and the neuropsychological/neurobehavioral symptoms.

Conclusions. While cross validation of these results are needed, this preliminary data suggests that the HDSC may be a practical and efficient way to identify those subjects who are at risk for developing HIV-related cognitive impairment. It may also help identify those individuals in need of neurological or NP evaluation.

This work has been supported in part by grant # DA04873 from the National Institute on Drug Abuse.

W.B.P.233 RELATING DEPRESSION TO NEUROPSYCHOLOGICAL IMPAIRMENT

Heaton, Robert; Atkinson, H; Grant, I; Weinrich, J. and McCutchan, A.
University of California, San Diego, La Jolla, CA, USA

Objective: Since depression can affect neuropsychological (NP) functioning, we assessed whether observed NP deficits in men with HIV illness might be due to depressed mood.
Methods: Subjects were 72 homosexual men (CDC IV, N=9; CDC II/III, N=41; HIV-controls, N=22) participating in a longitudinal study of NP functioning in HIV. Measures were an expanded Halstead-Reitan Battery (HRB) and four indices of severity of depressed mood: Beck Depression Inventory (BDI); Hamilton Rating Scale for Depression (HRSD); the Profile of Mood States (POMS) and Symptom Checklist -90R (SCL-90R) depression scales.
Results: Significant group differences were obtained in prevalence of impairment on three of the eight ability areas covered by the expanded HRB (abstraction, learning, motor skills), principally due to deficits in CDC IV men. Of 36 correlations computed between the eight NP ability areas and the four measures of depression there was only one significant (p < .05) result, which correlated greater motor impairment and higher HRSD scores. Subjects (N=12) with a lifetime history of major depression by DSM-III criteria did not show significantly greater NP impairment.
Conclusions: Results from this series suggest that NP impairment in ambulatory HIV infected men is not accounted for by depressed mood.

W.B.P.230 DISCRIMINATING DEPRESSION FROM COGNITIVE IMPAIRMENT IN HIV ILLNESS

Grant, Igor; Olshen, R.; Atkinson, H.; Heaton, R.; Weinrich, J.; McCutchan, J.; et al.
Univ of Calif,San Diego, CA, USA

Objective: To understand the relationship between depression and impaired neuropsychological (NP) performance in HIV illness.
Methods: Subjects were ambulatory homosexual men classed as CDC IV (N = 37) and CDC II-III (N = 58); and HIV negative homosexual (N = 34) and heterosexual (N = 27) controls, matched for age and education. Measures were a comprehensive NP battery and various measures of mood, including the Profile of Mood States (POMS). Recursive partitioning was used to classify subjects according to a decision tree approach using quantitative measures of cognitive impairment (NP) and depression (D).
Results: On the basis of optimally chosen yes-no questions regarding NP and D covariates, a test of speeded information processing (PASAT) most rigorously discriminated D from NP impairment. The decision tree yielded three subgroups, in which NP+ indicated abnormal PASAT and D+ was depressed based on POMS-D > 15: In Group 1 40/47 CDC IV were NP+/D-; In Group 2 52/61 controls were NP-/D-; and Group 3 consisted of CDC II-III men: 44/58 NP-/D-, 11/58 NP-/D+, 3/58 NP+/D-. Measures of verbal and visual learning and forgetting displayed less discrimination.
CONCLUSION: Recursive techniques suggest depressed mood can be separated from NP impairment in HIV. Application of advanced statistical approaches to classification hold promise for further exploration of cognitive function and in mood disorder in HIV illness.

W.B.P.232 CORRELATION OF P300 AUDITORY EVOKED POTENTIALS (AEPs) AND TESTS OF COGNITIVE FUNCTION IN HIV POSITIVE DRUG USERS.

Vincent Egan, A Chiswick, G Goodwin, D St Clair, RP Brettle. Depts. of Psychiatry/Infectious Diseases, EDINBURGH, Scotland. UNITED KINGDOM

OBJECTIVE: In cortical/subcortical dementias AEPs, particularly P3 latency (the time the brain takes to make a tonal discrimination) slow. Neuropsychological (NP) testing enables specific cognitive deficits to be assessed. A prospective study of synchronously-infected drug users currently examines electrophysiological, psychological and drug use factors.
METHOD: 33 subjects (CDC 2/3) were assessed using AEP and NP tests. P3 latency, P3 amplitude, memory, information-processing speed, cognitive function, and mood tests together with a drug history were recorded.
RESULTS: 5 of the 8 cognitive tests correlated significantly with P3 latency (Trails A 0.57, p<.001; Trails B 0.62, p<.001; Digit-Symbol Substitution -.53, p<.001; Logical Memory (immediate recall) -.57, p<.001, (delayed recall) -.47, p<.001; NART-estimated premorbid IQ, -.37, p<.02; Digit Span, -.41, p<.001). P3 amplitude was only associated with Logical Memory (r = 0.59, p<.001 and 0.42, p<.02 for immediate/delayed recall conditions respectively). Partialling-out years of opiates use, benzodiazepine use, amount of drugs taken in last 24 hours (range = 0-132 ml. of methadone) and Beck mood left the magnitude of P3 latency and amplitude/cognitive test correlations unaffected.
CONCLUSIONS: Tests sensitive to impairment in the AIDS dementia complex seem to correlate highly with slowed electrophysiology, and are not attributable to either long or short-term drug effects, or mood state.

W.B.P.234 THE DEVELOPMENT OF A BRIEF SCREENING BATTERY TO DETECT COGNITIVE DEFICITS IN PATIENTS WITH AIDS

Boccellari A.; Davis, A.; Dilley, James W.
San Francisco General Hospital, University of California San Francisco School of Medicine, Dept. of Psychiatry, and UCSF AIDS Health Project, San Francisco, California, U.S.A.

Objective. To determine the clinical value of a brief screening battery in detecting cognitive deficits in patients with AIDS.
Methods. Fifty patients with AIDS were given the following battery of Neuropsychological tests (NP):
Trail Making Test Part A & B (TMT)
Wechsler Memory Scale Logical Memory & Visual Reproduction, Immediate & Delayed Memory (WMS)
Shipley Institute of Living Vocabulary & Abstraction Scores
Finger Tapping Test (FTT)
Controlled Oral Word Association Test
Luria Nebraska Receptive Speech & Visual Schemas
Digit Span
Each individual NP measure was converted to a Z score equivalent. A sum of Z representing overall NP status was then achieved. A multiple regression analysis determined which combination of NP instruments best predicted overall NP impairment.
Results. Overall NP impairment was best predicted by: TMT (Part B), FTT, and WMS (Visual Reproduction). These measures accounted for 87% of the variance (p<.01).
Conclusions. These findings are consistent with previous research suggesting that HIV infection of the central nervous system is related to the development of mental slowing, reduced mental flexibility, decreased fine motor speed and difficulty with visual spatial memory in patients with AIDS. While cross validation is needed, this preliminary data supports the use of this brief screening battery in determining cognitive deficits in this population.

This work has been supported in part by grant # DA04873 from the National Institute on Drug Abuse.

W.B.P.235

NEUROPSYCHOLOGICAL FUNCTIONING IN HIV-INFECTION

Schick,U.*,Perro,C.*,Naber,D.*,Goebel,F.D.**
*Psychiatrische Klinik der Universität München
**Medizinische Poliklinik der Universität München
F.R.G.

Objective.To study the natural history of neuropsychological deficits in patients with HIV-infection.
Methods.132 HIV-positive patients,100 in early stages,underwent psychiatric exploration and neuropsychological testing.Psychopathology was rated by means of the AMDP-System,self-rated by SDS,POMS,STAI and SCL.Neuropsychological examination included "Maze","Vocabulary","Similarities","Digit-Symbol","Color-Word-Interference","Benton","Trail-Making" and "Auditory-Verbal-Learning".
Results.27% of patients showed symptoms of depression,3% of anxiety.Tests revealed normal functioning in 70% of patients in early stages and in 41% in late stages.Clinically relevant was the deficit in 5% and in 19% respectively.The comparison with HIV-negative controls (n=100) showed for most tests a significant reduction already in early stages.These deficits correlated highly with the degree of affective symptoms.
Conclusion.Cognitive deficits already occur in early stages,but often without clinical relevance.This study does not qualify to differentiate somatogenic vs. psychogenic etiology,repeated measurements and correlations with neurological variables are in process.

W.B.P.236

QUALITATIVE ASPECTS OF DEPRESSED MOOD AND NEUROPSYCHOLOGICAL FUNCTION IN HIV-1 +/- GAY AND BISEXUAL MEN: The Multicenter AIDS Cohort Study (MACS).

James T. Becker, F.W. Schaerf, L. Kingsley, R. Fox, & M.A. Dew. Depts. Psychiatry, Neurology & Epidemiology, Univ. Pittsburgh Sch. Med., and Johns Hopkins Med. Inst., U.S.A.

OBJECTIVES: This study evaluated the relationship between measures of affect and cognitive function in HIV-1(+/-) gay/bisexual men.
METHODS: HIV-1 seropositive (n=157) and seronegative (n=113) gay/bisexual men from the Pittsburgh and Baltimore MACS sites completed the Beck Depression Inventory (BDI), Spielberger's State/Trait Anxiety Inventory (STAI), and a short battery of neuropsychological tests.
RESULTS: Overall, the HIV-1+ men had more symptoms of depression (i.e., BDI), but no increases in either State or Trait Anxiety. Furthermore, when the seropositive men were categorized based on total number of CD4 cells there were significant differences only in terms of the total BDI score, which was elevated in the men with the lowest CD4 counts. This elevation was not due to an increase in the number or severity of symptoms of abnormal affect (e.g., "dissatisfied with life"), but rather an increase in the number and/or severity of physical symptoms (e.g., weight change) reported on the BDI. No differences in performance on the cognitive tests were seen between serostatus groups. Performance was correlated with the BDI but not the STAI. Further analysis revealed that it was the physical symptoms of depression rather than the affective symptoms which were related to cognitive function.
CONCLUSIONS: These data indicate that the assessment of mood in HIV-1-infected individuals must take into account physical illness. Consistent with other findings from the MACS, neuropsychological performance was predicted by the presence of physical symptoms, but not by dysphoric mood.

EVALUATION OF TRAINING FOR PHYSICIANS AT THE NATIONAL REFERENCE CENTERS IN BRAZIL

Rodrigues, José*; Rodrigues, Lair**
* Universidade de Brasília – Brazil, **Ministério da Saúde – Brasília, Brazil

Under the sponsorship of the National Division of STD/AIDS, an evaluation of the clinical training on AIDS delivered by the three Reference Centers--Emílio Ribas (ER), Universidade Federal do Rio de Janeiro (UFRJ) and Gaffrée & Guinle (G&G)--was carried out. The evaluation took into account guidelines set up by the National Comission on AIDS and derived its framework form Stufflebeam's evaluative model (1977). The model comprises four components--Context, Input, Process and Product--which corresponded to the aspects to be assessed in the evaluation. Instruments of three kinds were used: (a) interviews with those in charge of the Reference Centers, (b) direct observations by the evaluator, and (c) three paper-and-pencil instruments, i.e., the Knowledge Test on AIDS, the Interpersonal Skills Inventory, and the Course Evaluation.
The scores derived from the trainees' responses--ER, UFRJ, and G&G--to the Knowledge Test and the Course Evaluation Showed no statistically significant differences according to the Kruskal-Wallis method (1975). However, a closer look into particular aspects of the three Centers showed positive characteristics as well as aspects deserving improvement. Such data allowed of some extrapolations pertaining to the evaluator, the DN STD/AIDS, the Reference Centers and the entities responsible for the trainees.

W.B.P.238

A COMPREHENSIVE APPROACH TO COMMUNITY HOSPITAL CARE OF AIDS PATIENTS

Andrews, Laurie; Klimek, J. (Hartford Hospital, Hartford, Connecticut, USA)

Objective. To provide clinical care, education, counseling, testing and social services to HIV infected patients (pts) served by an 850 bed tertiary care community teaching hospital in central Connecticut.
Methods. An AIDS Task Force acts in a reflective and advisory capacity, recommending policy and procedure to the Infection Control Committee. A patient oriented multidisciplinary HIV Team coordinates the delivery of services to in-pts with HIV disease and provides support to hospital staff. Community based volunteers provide support and social services for HIV pts and families. An AIDS Program office provides an INFO-line, resource referral and speakers for community groups. A newsletter is periodically distributed updating national and regional AIDS related developments. The hospital provides referrals and acts as a resource for various community based organizations which provide education, outreach and support. The hospital is part of a city wide network of social service agencies coordinating community services. Close, collaborative working relationships have been established with local Health Depts., the Visiting Nurse Association and area church groups. A regional task force has established a data base, and addresses public policy and legislative issues.
Conclusion. Since each hospital's HIV population and problems are both generic and specific, internal coordination and problem solving must be coupled with the establishment and strengthening of links to community services in order for both the hospital and its patients to survive.

W.B.P.239

INVERSE CORRELATION OF COMPLEMENT-MEDIATED, ANTIBODY-DEPENDENT ENHANCING TITERS WITH STAGE OF DISEASE IN INDIVIDUALS INFECTED WITH HIV-1.

Mitchell, William M., Montefiori, D.C., Robinson, W.E., Jr., Modliszewski, A., and Lefkowitz*, L.B., Jr. Depts. Pathology and *Preventive Medicine, Vanderbilt University, Nashville, TN 37232 USA

Objective: Complement-mediated, antibody-dependent enhancement (C'-ADE) of HIV-1 infection has been demonstrated to accelerate infection, to inhibit neutralizing antibody titers *in vitro* (Lancet i:790, 1988), and to cause a > 100 fold increase in infectious HIV-1 yields (*JAIDS* - in press). Our objective in this report is to ascertain whether titers of antibodies involved in C'-ADE and the relationship between neutralizing antibodies and C'-ADE correlate with stage of disease.
Methods: Sera from twenty-eight subjects in the Nashville area were examined at a single time point for C'-ADE titers as well as neutralizing antibodies in the presence or absence of human complement. Stage of disease was evaluated by the Walter-Reed classification scheme. C'-ADE as well as the ratio between neutralizing antibodies in the absence and presence of human complement and the ratio between C'-ADE and neutralizing antibody titers in the absence of complement were correlated with disease stage by linear regression analysis.
Results: No correlation between neutralizing antibody titers in the presence and absence of complement or C'-ADE and neutralizing antibodies was found with the stage of HIV-1 induced disease. An inverse correlation between C'-ADE and the stage of disease appears to exist but with considerable scatter of the data points ($r = -0.4$) on initial analysis of a limited number of subjects.
Conclusion: The data in human subjects is consistent with our observation in chimpanzees following initial challenges with HIV-1: C'-ADE titers rise prior to neutralizing antibody titers. Titers of the latter increase as C'-ADE declines. Efforts will continue to expand our data base to correlate with stage of disease as well as to examine the speed of disease progression as a function of C'-ADE.

W.B.P.240

IMPEDIMENTS TO IVDA ENROLLMENT IN ACTG CLINICAL TRIALS

Fairchild, Patrick; Jaffarian, C; Cheeseman, S; Bova, C; Tolson, K; Blacklow, N; et al. University of Massachusetts Medical School, Worcester, Massachusetts, USA.

Objective: To ascertain reasons that hinder enrollment of HIV-infected intravenous drug abusers (IVDA) into clinical trials.
Methods: One hundred forty one IVDA (76 males + 65 females) were evaluated at UMMS for entry into NIH ACTG clinical trials assessing AZT in asymptomatic infection (protocol 019) and early ARC (protocol 016) utilizing standard inclusion and exclusion criteria.
Results: Of the 141 patients, only 38 (27.0%) were considered eligible for study protocol. Eleven (7.8%) of the 141 patients have been enrolled, 15 (10.6%) eligible patients are considering entry and 12 (8.5%) have refused participation in study. IVDA's considered ineligible for study (103 patients) often had more than one reason for not entering a protocol. These included psychosocial difficulties (53.1%), active IV drug use (23.4%) and exclusion for medical conditions (40.0%). IVDA that entered and remained in study were more likely to be enrolled in a long-term drug free residential facility or have a stable and supportive home environment than those who did not enter study. In contrast, of 78 non-IVDA, 49 (62.8%) were considered eligible for study and 19 (24.4%) were enrolled.
Conclusions: Multiple factors contribute to the low enrollment rate of IVDA into clinical trials. Increased availability of social service support and improved access to drug rehabilitation facilities may enhance IVDA participation in clinical trials. Expanded medical study inclusion criteria and less restrictive exclusion criteria may further promote entry into study.

W.B.P.241 ~~THE ROLE OF THE GOVERNMENT OF CANADA IN THE NATURE~~ AND DIRECTION OF CLINICAL RESEARCH IN THE MANAGEMENT OF HIV-DISEASE IN CANADA

Wabih R. Khan AND N.N. Joshi
Infection and Immunology Division, Bureau of Human Prescription Drugs, Drugs Directorate, Health Protection Branch, Ottawa,Canada

Objective: To identify and discuss the key role played by Health and Welfare Canada in supporting, expediting, facilitating, and implementing clinical research in the management of HIV-disease in Canada.

Methods and Results: The Health Protection Branch (HPB) of Health and Welfare Canada plays a crucial but delicate role in determining patient accessibility to experimental drugs for the management of HIV-disease and its ancillary opportunistic infections and neoplasms. New policy initiatives and administrative changes have been recently announced which are intended to streamline the regulatory process and improve patient accessibility. It is our intention to examine the impact of these changes on the availability of experimental agents in Canada and on the climate for clinical research in this country. In addition, we will discuss the mechanisms for the introduction of experimental agents in Canada, the organizational and regulatory framework of HPB, the philosophy governing the evolution and implementation of regulatory change, and the consultative role of the Drugs Directorate.

Conclusion: The Health Protection Branch will continue to play a key role in improving patient accessibility and promoting clinical investigation in the management of HIV-disease in Canada

W.B.P.242 THERMOGRAPHIC IMAGING OF HIV PATIENTS

Clark, Ray *, Goff, M.R.*, Youle, M**, and Gazzard, B**.
*Clinical Research Centre, Harrow, UK & **St. Stephens Hospital, London, UK.

Objective. To assess the role of high resolution infra-red imaging in HIV infection and Kaposi's sarcoma with particular reference to monioring abnormal patterns that may arise because of peripheral neurological impairement and/or the presence of KS lesions.

Methods. High resolution thermal imaging equipment using an 8 element SPRITE detector system working in the 8-13 micron waveband has been used in a study to assess whole body skin temperature patterns in 20 HIV positive patients with biopsy proven KS lesions and to determine the thermal status of representative KS lesions before and during treatment with iodostearic acid.

Results. Characteristic and abnormal thermal patterns were found in a high proportion of the patients studied. In addition, a range of quantifiable thermal activity of KS lesions at different body sites was recorded. Some lesions showed measurable changes in thermal activity during treatment. These findings will be illustrated.

Conclusion. It is suggested that cutaneous neurological changes associated with HIV infection may produce abnormal thermal patterns on the skin surface and that the technique of infra-red thermography may have a role in identifying such abnormalities and provide an index of peripheral neurological change in HIV patients. Thermographic patterns may also be able to characterize the vascular and metabolic status of cutaneous lesions and thereby help in the assessment of the activity of Kaposi's sarcoma.

W.B.P.243 ART THERAPY WITH PEOPLE WITH AIDS

Eva Sansom, M.A. Couns., Psych., D.T.A.T.I.
Counsellor, Art Therapist
Casey House Hospice Inc.
Toronto, Ontario, Canada

Abstract:

Art Therapy is a useful medium for the expression, recognition and processing of the anxieties of People With AIDS.

In this paper and slide presentation, issues of pain, incompletion, failure, isolation, dependency, punishment, fear of the unknown and homophobia are expressed in the artwork and subsequent discussion.

The workshop will present one PWA artwork produced over the course of 3 months to illustrate the development of the process of art therapy. Several other examples of specific statements through artwork will also be shown. Two aspects of denial will be suggested.

W.B.P.244 MAINTENANCE OF HOPE IN AN HIV SAMPLE

Rabkin, Judith, Williams, J., Neugebauer, R., Remien, Robert
HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, NY, NY, USA

Objective: To identify social and psychological conditions, susceptible to intervention, that contribute to maintenance of hope in an HIV sample.

Methods: 156 gay, predominantly white, well educated and financially successful community volunteers were evaluated to identify overall level of psychological functioning, psychiatric syndromes and symptoms, life outlook, social relationships, life events, HIV status and illness stage. 73% of participants were HIV seropositive.

Results: The following were positively associated with higher levels of hope (Pearson r's, $p < .02$): social supports (+0.52), internal locus of control (+0.36); commitment (+.060); number of positive life events (+0.28), and global psychological functioning (+0.31). HIV illness stage and T cell count among HIV+ subjects were not significantly related to level of hope. In the absence of current psychiatric disorder (DSM-III-R), mean difference in level of hope between HIV+ and HIV- subjects was not statistically significant. There was, however, more variability of response and more extreme scores within the HIV+ group, at both ends of the distribution.

Conclusion: The large majority of respondents have been able to preserve a sense of faith in the future and the conviction that living is worthwhile, despite HIV infection.

W.B.P.245 A REHABILITATION PROGRAM FOR CLIENTS WITH HIV ASSOCIATED CONDITIONS

Gentile, Patricia, Marshall K., Bennett M., Laqueur P., Alexander H., Davis I.- Woodhull Medical & Mental Health Center, Brooklyn, NY, USA

Objective. This poster presentation will highlight the special and unique role Rehabilitation Medicine can provide in servicing people with AIDS (PWAs).

Methods and Results. Woodhull Medical & Mental Health Center, as part of NY City's Health & Hospitals Corporation, provides comprehensive tertiary-care service to a large impoverished and medically underserved community. As part of the Department of Ambulatory Care, Rehabilitation Medicine offers physical and occupational therapy services to a wide variety of patients, including those diagnosed as having AIDS or AIDS-related complications. The growing number of PWAs is challenging all health care specialities to define their role in providing services to this population; Rehabilitation Medicine is no exception. PWAs or AIDS-related conditions may present with a wide variety of physical, emotional, and psychological problems. Consequently, the role of Rehabilitation Medicine will include: 1) maximizing level of functioning in activities of daily living; 2) supporting continued participation in occupational roles; and 3) improving the quality of life.

This presentation will describe and demonstrate a therapeutic rehabilitation group developed for PWAs. Lead by an occupational therapist, the goals of the group lie chiefly in teaching coping and adaption skills specifically for PWA's. Conditioning exercises, breathing and relaxation activities, and self-care training are integral parts of the comprehensive program.

Conclusion. People with AIDS are faced with the daily challenge of living with their condition. This presentation will highlight what role Rehabilitation Medicine, especially occupational therapy, can play in promoting skills to achieve maximal independence.

W.B.P.246 COMPLIANCE OF HIV-INFECTED INTRAVENOUS DRUG USERS IN CLINICAL TRIALS

Cheeseman, Sarah; Fairchild, P; Glode, M; Tolson K; Jaffarian, C; Blacklow, N; et al. University of Massachusetts Medical School, Worcester, Massachusetts, USA.

Objective: To compare compliance of clinical trial subjects whose risk factor is intravenous drug abuse (IVDU's) with those from other risk groups.

Methods: Subjects are UMass patients in NIH ACTG placebo-controlled trials of zidovudine in asymptomatic infection (019) and early ARC (016). IVDU's were either drug-free or on methadone maintenance at the time of protocol entry. The number of pills returned at each visit was tallied and periods for which patients returned < 20% of study drug were deemed to represent good compliance. This corresponds to missing no more than one dose per day.

Results: Four of 11 IVDU's have left the studies for reasons other than protocol endpoints, compared with one of 20 from other risk groups. All 5 were asymptomatic. None of the 9 patients with symptoms of early ARC have left 016, although 4 are IVDU's.

	Percent of Study Weeks in Good Compliance	
	IVDU's	Others
All patients on study	92	93
016 (early ARC)	99	94
019 (asymptomatic)	86	93
1st 15 weeks (biweekly follow-up)	90	95
≥ 16 weeks (monthly follow-up)	98	89

Conclusion: Although IVDU's discontinue study participation more often than others, their adherence while on study, as measured by pill returns, does not differ markedly from subjects from other risk groups.

W.B.P.247 INSURING QUALITY OF DATA IN COMMUNITY-BASED CLINICAL TRIALS

Mitchell, T.*; Child, C.*; Weingart, Z.*; and Abrams, Donald*
*San Francisco County Community Consortium, San Francisco,USA

Community-based clinical trials of experimental HIV treatments offer the potential for rapidly expanding the number of drugs being tested, increasing participation by community physicians in HIV research, and improving access to promising experimental therapies for large numbers of patients. Critics of community-based clinical trials, however, argue that the quality of data obtained in community settings is unlikely to achieve standards established in academic research settings.

To meet this challenge, the San Francisco County Community Consortium (SFCCC) designed data collection, protocol management and quality assurance systems which could be implemented in community physicians' offices. In Fall 1988, the SFCCC trained 45 physicians to use these systems and launched 5 clinical trials. Studies include Phase II/III trials of readily available agents as well as observational databases of current HIV therapies.

To insure consistent data collection by large numbers of physicians located over a wide geographic area, the SFCCC uses the same set of case report forms for all clinical trials. To minimize the amount of record keeping required of physicians, the SFCCC staff use a computerized followup system to prompt physicians to collect data and to dispense study medications at prescribed intervals. To insure data are recorded accurately and completely, SFCCC staff systematically review all case report forms before data are removed from physicians' offices and entered into the SFCCC database management system.

The experience of the SFCCC suggests that frequent (weekly) monitoring by research staff is necessary but sufficient to insure that data collected in community settings achieve standards established in academic research centers.

W.B.P.249 AIDS TREATMENT REGISTRY (ATR) OF NEW YORK

Long, Iris.; Cowing, M.; Eigo, J. and Huff, R. AIDS Treatment Registry, P.O.B. 30234, New York, New York, USA.

Objective. To provide information about ongoing clinical trials to individuals seeking to enroll in clinical trials, physicians, health facilities and AIDS service organizations in New York and New Jersey.
Method. A local, non-profit organization has established a computerized database to give accurate, reliable information on AIDS-related clinical trials because up-to-date, accurate information is not easily accessible.
Results. It is generally accepted that access to health care and experimental treatments will extend the lives of many infected with HIV. Acquiring information about clinical trials is limited. This has led to underrepresentation of minorities and overall underenrollment in trials. The latter is one of the factors slowing down the drug approval process. According to the Food and Drug Administration, there are currently over 80 drugs approved for trials and over 100 drug trials. In October 1988, a federal law was enacted requiring sponsors of AIDS drug trials to make public all AIDS efficacy trials. The impact of the new legislation on the project will be discussed.
Conclusion. The ATR will identify all AIDS/HIV-related clinical drug trials underway locally, collect data from principal investigators conducting such trials to determine where "open slots"exist and what is required of prospective drug trial participants. This information will be developed into a readily accessible report format and distributed to all potential end-users.

W.B.P.251 PROGRAM DIRECTORS' ATTITUDES TOWARDS RESIDENTS' CARE OF PERSONS WITH AIDS.

Hayward, R. A.*; Kravitz, R. K.**; Shapiro, M. F.**. *University of Michigan, Ann Arbor, Michigan, United States. ** University of California, Los Angeles, California, United States.

Objective. To evaluate the educational strategies and experiences of United States residency programs regarding the training of primary care providers for persons with AIDS (PWAs).
Methods. We mailed questionnaires to directors of all 772 non-military United States internal medicine (IM) and family medicine (FM) programs. 59% have responded.
Results. While 91% of directors felt that primary care of PWAs is an important educational experience and 94% of programs reported usually having AIDS inpatients, only 15% reported that the majority of trainees cared for PWAs in their continuity clinics. Even at programs with a high inpatient load (average census ≥ 6), only 39% reported that most residents had either cared for a PWA in their continuity clinic or had rotated through an AIDS subspecialty clinic. More IM than FM directors considered care of PWAs to be too complicated for most generalists (24% vs 9%, $p<0.01$) and IM directors were less likely to encourage housestaff to provide PWAs with primary care (51% vs 72%, $p<0.01$). Among 57% who did not believe or were unsure if their residents were adequately trained in AIDS ambulatory care, only 38% reported improving education in this area to be a high priority. Among the 39% who do not encourage residents' assumption of primary care, 60% had at least one of the following concerns: resident stress (24%), AIDS care too complicated (31%), or clinic faculty not qualified to supervise them (39%).
Conclussions. While program directors view education in ambulatory care of PWAs as important, most do not believe residents are adequately trained, many do not encourage residents' assumption of primary care of PWAs and residents have not provided such care in their programs. Strategies to augment residents' ambulatory experience in the care of PWAs are needed.

W.B.P.248 EVALUATION DE LA CHARGE DE TRAVAIL INFIRMIER : COMPARAISON ENTRE PATIENTS HOSPITALISES INFECTES ET NON INFECTES PAR LE VIH.

CHIDIAC Christian, CHAUSSOY D., BEAUCAIRE G., LEROY O., SENNEVILLE E., MOUTON Y. Service des Maladies Infectieuses. Centre Hospitalier. F 59208 TOURCOING, FRANCE.

La structure et l'intensité des soins infirmiers ont été étudiés fin 1988 de manière prospective dans un service universitaire de Maladies Infectieuses par recueil quotidien des informations. 64 dossiers sont évaluables : 29 patients infectés par le VIH (dont 19 IVC1 ou IVD) et 35 patients hospitalisés pour pathologie infectieuse ou parasitaire non VIH, correspondant respectivement à 516 et 342 journées d'hospitalisation. Les soins de base (alimentation, locomotion, mobilisation, élimination, hygiène et confort), techniques (diagnostiques et thérapeutiques), relationnels et éducatifs, sont classés de 1 à 5 en fonction de leur intensité.

Intensité des soins

		1	2	3	4	5
	minute/jour	1,8	29,5	55,2	87	5,0
VIH+	(%)	(1)	(16,6)	(30,9)	(48,7)	(2,8)
VIH-	minute/jour	1,3	52,5	36,6	22,6	0,51
	(%)	(1,1)	(46,2)	(32,3)	(20)	(0,4)

Structure des soins

		base	technique	relationnel
VIH+	minute/jour	47,3	40,8	90,5
	(%)	(26,5)	(22,9)	(50,6)
VIH-	minute/jour	33,3	49,2	30,9
	(%)	(29,3)	(43,4)	(27,3)

Les patients VIH+ requièrent des soins relationnels maximum. L'intensité des soins est doublée par rapport aux patients VIH-.

W.B.P.250 ATR: A REGIONAL MODEL FOR ESTABLISHING A COMMUNITY-BASED, COMPUTERIZED REGISTRY OF AIDS/HIV CLINICAL DRUG TRIALS.

Eigo, James; Cowing, M.; Long, I. AIDS Treatment Registry, Inc. (ATR), P.O. Box 30234, New York, New York 10011 U.S.A.

Objective: To establish community-based registries of AIDS/HIV-related clinical drug trials at local levels to increase awareness of, and access to, such trials for all persons affected by the epidemic, especially among minority populations heretofore largely excluded from enrollment.
Method: Discussion of the steps taken by the ATR to gather information on AIDS/HIV-related clinical trials underway in their area and disseminate that information to members of all affected populations, including intravenous drug users (IVDUs), Blacks and Hispanics, women and children, and the poor. Discussion topics will include: becoming your own "expert" on clinical trials; developing a database; developing data collection materials; volunteer recruitment and training; overcoming obstacles in collecting data; producing "user-friendly" report formats; developing culturally sensitive education materials covering trial enrollment issues and the use of experimental drugs; establishing a community outreach and distribution network; and qualifying for available funding.
Results: ATR's effort has been highly successful. They have obtained the aid of City and State health officials in collecting trial data and were funded by N.Y. State in their first year of operation. A bi-lingual "Handbook for Clinical Trial Participants" has been produced. Trial enrollment statistics are closely monitored to quantify the overall impact of the effort. Conclusion: A community-based registry of trials can promote greater access to potential treatments and enhance trial enrollment.

W.B.P.252 IMPACT OF SERUM P24 HIV ANTIGEN SCREENING ON PATIENT ELIGIBILITY FOR ANTIVIRAL CLINICAL TRIALS

Heath-Chiozzi, Margo; Pearlstein,G.; Eigenrauch,H.; Crumpacker,C.; Cotton,D. Beth Israel Hospital, Harvard AIDS Clinical Trials Unit, Boston, MA, USA.

Objective. To examine the impact of serum p24 HIV antigen (p24) screening on patient eligibility for an antiviral clinical trial.
Methods. [ACTG #034 Phase I Trial of Ribavirin in the Treatment of Patients with AIDS and Advanced AIDS-Related Illnesses (ARC)] requires positive serum p24 for inclusion. Screening interviews and review of medical records determined clinical stage of HIV-related illness and Zidovudine (AZT) use. Blood was obtained from patients with ARC or AIDS and serum tested for p24 using the Abbott ELISA. A level of ≥ 70 picogram/ml was interpreted as positive (+) and qualified patients for study enrollment.
Results. 45 patients were screened to the point of p24 testing with the following results:

31 p24 +	14 p24 -
8 ARC; 23 AIDS	4 ARC; 10 AIDS
15 had prior AZT use	4 had prior AZT use

P24 positivity did not significantly correlate with either clinical stage or AZT use by Chi square analysis. Four - patients were later retested and 2 had converted from - to +.

Seventeen + patients have been serially tested and have remained +.

Conclusion. Use of p24 positivity as an eligibility criterion for phase I antiviral trials will limit access of significant numbers of clinically indistinguishable patients to these trials. The impact of such exclusion on patient accrual and on the applicability of trial results may be significant.

W.B.P.253 NEW DEVELOPMENTS IN A MODEL PROGRAM OF AIDS HOSPICE CARE.

Bruce Priebe, RN; Visiting Nurses and Hospice of San Francisco, CA, USA

OBJECTIVE
To present the most current developments in a model program of comprehensive AIDS hospice care.
METHODS
For five years Visiting Nurses and Hospice of San Francisco has provided both residential and inpatient AIDS hospice care. Utilizing interdisciplinary teams of nurses, social workers, volunteer service coordinators and home health aides. VNH has cared for over 2,000 people with AIDS. The program is linked with other community resources, operating as an integral part of the continuum of care required for effective AIDS treatment. The program also includes pastoral services and bereavement follow-up with family members and care partners. For the past two years, the program has operated a fifteen bed hospice facility.
RESULTS
VNH has offered comprehensive services to 2,000 PWAs as well as hundreds of family members over a period of five years. We have trained thousands of people worldwide through direct contact and the development of training materials. Hospice care is an integral link in the widely acclaimed S.F. model of AIDS care, helping to keep costs per patient down to $100/day.
CONCLUSION
The VNH model of AIDS hospice care has proven to be successful medically, financially, and emotionally. Furthermore, it has shown its usefulness to many communities throughout the world, who have an increasing need to develop compassionate and cost-effective models of service delivery.

W.B.P.254 A BRIEF HEALTH STATUS INSTRUMENT FOR USE IN AIDS CLINICAL TRIALS

Wu, Albert W*; Rubin HR*; Mathews WC**; Bryk LM**; Hardy WD***; Grant I**; Richman DD** et. al. University of California, San Francisco*, San Diego**, and Los Angeles***, California, USA.

Objective. While drug trials for HIV infection would ideally measure patients' health status and quality of life, most available instruments are too long to be acceptable to investigators and subjects. We aimed to develop a brief yet valid questionnaire for use in clinical trials.
Methods. We modified the Medical Outcome Study Short-form General Health Survey to include subscales with particular relevance to HIV infection, such as energy and cognitive function. We studied whether this new 32-item instrument would measure health concepts reliably and distinctly and would discriminate between clinically different patient groups.
Results. We administered the instrument to 73 subjects with asymptomatic HIV infection and 44 with AIDS-Related Complex (ARC). Respondents were able to complete the questionnaire in less than 5 minutes. Questionnaire items were more highly correlated with items in the same subscale than with items in other subscales. Reliability coefficients were greater than 0.78 for all but one of the multi-item subscales. Compared to patients with ARC, asymptomatic patients had significantly less pain (difference between means 0.7; 95% C.I. 0.5,0.8), more energy (1.4; C.I. 0.5,2.2), better physical function (0.6; C.I. 0.5,0.7) and cognitive function (1.6; C.I. 1.0,2.3), and superior overall health (0.5; C.I. 0.3,0.8). The groups scored similarly on subscales of social function, mental health, and health distress.
Conclusion. We conclude that the instrument is acceptable to patients, reliably measures distinct health concepts, and discriminates between clinically different groups of patients with HIV infection.

W.B.P.255 NEUROPSYCHOLOGICAL TEST PERFORMANCE IN HIV-1 SEROPOSITIVE PATIENTS ON AND OFF AZIDOTHYMIDINE (AZT)

Sidtis, John J; Sadler, AE; Keilp, J; Brew BJ; Aronow, HA & Price RW. Memorial Sloan-Kettering Cancer Center, NY, NY, USA

Objective. To compare the levels of neuropsychological and neurological performance in patients treated with ad hoc AZT with untreated patients.
Methods. The Neuro-AIDS Study Group (NASG) neurological history, examination, and neuropsychological battery was administered to HIV-1 seropositive patients at various stages of disease: a group not receiving AZT (evaluations=374) and a group receiving AZT (evaluations=187).
Results. There was no significant group difference in a composite score based on the neurological history and examination. Despite a significantly higher mean Walter Reed Stage in the treated (5.9) compared to the untreated group (4.7) ($t=8.65$; $p<0.001$), a composite neuropsychological impairment score was higher in the untreated group ($t=3.06$; $p=0.002$). Tests showing the largest group differences included: Trail Making B (24%) and A (13%), and errors on the Benton Visual Retention Test (25%).
Conclusions. Although the overall neurological status was not significantly different in the groups treated and untreated with AZT, the NASG neuropsychological test battery demonstrated significantly better performance in the treated group. Whereas the functional significance of such differences remain to be determined, neuropsychological evaluation is effective in quantifying subclinical changes in HIV-1 seropositive groups.

W.B.P.256 TEST-RE-TEST PERFORMANCE ON NEUROPSYCHOLOGICAL TESTS IN A GROUP OF HIV-1 SEROPOSITIVE PATIENTS

Sadler, Abigail E; Keilp, JG; Thaler H, Brew BJ, Aronow HA, Price, RW & Sidtis, JJ. Memorial Sloan-Kettering Cancer Center, NY, NY, USA

Objective. To accurately evaluate test-re-test performance on the Neuro-AIDS Study Group (NASG) neuropsychological battery. In order to assess efficacy in treating the AIDS Dementia Complex (ADC) in prospective therapeutic studies, the effects of repeated testing must be understood.
Methods. A heterogeneous group of HIV-1 seropositive patients who were evaluated for AIDS Dementia Complex using the NASG neurological history, examination, and neuropsychological battery twice within a 12 week period served as subjects. Only patients not receiving anti-viral therapy, and not changing overall dementia or motor ratings on the neurological examination were included (n=27).
Results. The median time between evaluations was 7.4 weeks. There were no significant differences between time 1 and time 2 scores on any of the tests. For patients with normal motor function (n=14), performance on 9/13 tests decreased at re-administration (mean=5.9%) while 4/13 increased (mean=5.3%). For patients with mild dysfunction (n=9), the average decrease (6 tests) was 12%, the average increase (6 tests) was 4.8%.
Conclusions. Although disease progression can mask practice effects, with appropriate administration, practice effects on the NASG neuropsychological tests do not appear to be a significant factor in repeated measures studies of HIV-1 seropositive subjects.

W.B.P.257 NEW MODALITIES FOR CLINICAL TRIALS: A SYNTHESIS OF PHARMACOLOGY AND HEALTH CARE.

Harrington, Mark; Eigo, J.; Kirschenbaum, D.Z.; Long, I.
AIDS Coalition to Unleash Power, New York NY, USA.

Objective: To resolve the contradictions between the goals of those conducting clinical trials, who seek data, and those participating in them, who seek health care. Method: Protocol analysis, discussions with clinicians, researchers, officials and patient advocates. Discussion: <5,000 people,(<0.5% of the HIV+ US population) are enrolled in NIAID's ACTG program. Accrual is impeded by poor outreach, poor trial design, inaccessability, denial of PCP prophylaxis and reluctance to enroll in placebo-controlled trials. Data are skewed by subjects' recourse to unapproved drugs off trial. A growing consensus among the medical establishment and AIDS advocates is calling for new trial designs which guarantee treatment, allow prophylaxis and eschew placebos for life-threatening conditions. San Francisco and New York clinicians have begun treatment protocols with computer modeling of serologic and clinical results to evaluate optimal dosages and combinations. Conclusion: Clinicians, researchers and patient advocates can cooperate to develop new modalities for wider, faster, better-designed and more humane drug trials embodying a new synthesis of scientific and therapeutic aims.

W.B.P.258 CO-MORBID EVENTS IN FIRST HIV IDENTIFIED HOSPITALIZATIONS, NEW YORK STATE (NYS), 1984-86

DiFerdinando, George Jr.; Arthur, K.; Kaufman, G.
New York State (NYS) Department of Health, Albany, NY, USA.

Objective To describe the disease experience in those first hospitalized with HIV infection and/or sequelae in NYS acute care facilities between 1984 and 1986.
Methods Discharge data abstracts (DDA) from all non-federal acute hospital stays in NYS were searched; any DDA with an ICD-9-CM diagnosis of 042-049, 795.8, 279.10, 279.19, 279.30, or 136.3 was considered to have an HIV specific diagnosis (HIVSD). DDA were then linked by individual into an HIV longitudinal file (HIVLF). The first HIVLF discharge for each patient was reviewed for co-morbid events; diseases were designated as HIV related (HIVRD) if identified in the 1/88 ICD-9-CM revision of the HIV infection codes as associated with HIV; and as OTHER if not.
Results Of 13,014 who first appeared on the HIVLF between 1984-86, 9880 (75.9%) had an HIVRD on first DDA; total HIVRD=20,549 (1.6/person). 3134 (24.1%) persons had no HIVRD coded on their first DDA. Prevalent HIVRD were PCP 5705 (27.8%); Candidiasis, 3006 (14.6%); Anemia Group, 281 (11.1%); KS 1204 (5.9%); TB Group, 817 (4.0%); septicemia, 717 (3.5%); and pneumonia, 653 (3.2%). OTHER diagnoses frequently seen on DDA without any HIVRD were mental disorders (including drug abuse) (1529,19%); digestive system (361, 4.5%) or respiratory system disease (455, 5.7%); pneumonia/flu (321, 4%); and venereal disease, including syphilis (51, .6%)
Conclusion In first HIVLF admissions without an HIVRD, many have mental disorders or "garden-variety" pneumonia. Current ICD-9-CM codes may need to be expanded to include more non -traditional HIVRD to accurately reflect the extent of HIV morbidity.

W.B.P.259 NEUROPSYCHOLOGICAL PERFORMANCE AS A FUNCTION OF AIDS DEMENTIA COMPLEX (ADC) SEVERITY

Sadler, Abigail E; Keilp, JG; Dorfman, D; Brew, BJ; Aronow, HA; Price, RW & Sidtis, JJ. Memorial Sloan-Kettering Cancer Center, NY, NY, USA

Objective. To review the sensitivity of the Neuro-AIDS Study Group (NASG) neuropsychological battery as a function of clinical severity of cognitive, motor, and behavioral dysfunction in ADC.
Methods. 210 HIV-1 seropositive patients at various stages of disease who were not receiving anti-viral therapy and whose evaluation for ADC was not confounded by other disease were evaluated using the NASG neurological history, examination and neuropsychological test battery.
Results. Patients were classified as normal, mild, moderate or severe with respect to cognitive, motor, and behavioral function based on neurological history and examination. The following tests revealed significant ($p<.05$) decrements across all 3 clinical severity classifications of both cognitive and motor function: timed gait, finger tapping, grooved pegboard, trail making and digit-symbol transcription. In contrast, test performance only differentiated between normal and moderate to severe behavioral dysfunction. A composite neuropsychological impairment score revealed decreased performance across severity classifications for the dementia and motor ratings but not for the behavioral severity subgroups.
Conclusions. Performance on the NASG neuropsychological battery reflects the severity of cognitive and motor impairment. Although behavioral disturbances also occur, they do not have a comparable effect on neuropsychological test performance.

W.B.P.261 CLINIC FOR HIV-RELATED CONCERNS: ONE MODEL OF OUTPATIENT PSYCHIATRIC CARE

Hoo, Stephen.
Mount Sinai Hospital, Department of Psychiatry/University of Toronto, Toronto, Ontario, Canada.

Objective. To provide an example of a model of care for outpatient psychiatric and psychosocial services in Canada. Such a model can then be used as a basis for developing suitable clinics in other areas of the country where these services are required.

The Clinic for HIV-Related Concerns opened in July 1986. It is part of the Department of Psychiatry, Mount Sinai Hospital, Toronto. The objectives are to provide: (1) psychiatric and psychosocial services for persons affected by HIV disease, including family members and significant others. Services provided include individual, couple, family and group therapy; (2) a centre to which health care professionals and students can come to train in areas related to the psychiatric, neuropsychiatric and psychosocial aspects of HIV disease; (3) ongoing research, e.g. to develop a brief screening test for cognitive deficits in HIV infection.

Two hundred and fifty-eight persons have been assessed and treated between July 1, 1986 and December 31, 1988. Ninety-two are PWAs, 98 have other forms of HIV infection, 68 are not infected (including "worried-well"). Highest increase in referrals in last 12 months is of married bisexual/homosexual men and their wives. Feedback from patients, referring agencies and the Community Advisory Board of this Clinic is that such clinics are urgently needed for provision of care, liaison with the community, education and research.

W.B.P.263 SACRAMENTO CARES: ONE COMMUNITY'S RESPONSE TO PROVIDING COMPREHENSIVE MEDICAL CARE TO PEOPLE WITH HIV-RELATED DISORDERS

Flynn, Neil*; Riley J**; Pomerantz S**; Grant S**; Wolf M+; McCandless L++. *University of California, Davis (UCD); ** Representing: Sacramento Hospital AIDS Consortium; + CARES, Board of Directors; ++ Sierra Foundation. U.S.A

Objective. To develop a system of medical care to meet the need for comprehensive, coordinated, high-quality care for people with HIV infection in the Sacramento, CA area, which has a total of >600 reported cases of AIDS.
Methods. To reach our objective, local hospitals, AIDS agencies, physicians (P), and a regional philanthropic foundation (SF) formed a task force in 9/87 to study the problem. It recommended creation of the Sacramento Center for AIDS Research, Education and Services (Sacramento CARES), a private, non-profit corporation. SF, local hospitals, and county and state governments have provided initial funding for the project.
Results. The facility will open in 5/89 and accommodate 300 visits/mo, expanding to 1500/mo by 1992. It is designed to attract private practice and academic P to carry out their HIV-related practice and clinical research activities. It plans to offer: an attractive site; a private practice setting for private P and their patients (pts); a clinic setting for "public" and "academic" P and their pts; formal affiliation with UCD; computerized pt records designed to facilitate clinical research; on site medical, transfusion, phlebotomy, pharmacy, dental, psycho-social, case management and drug abuse services; AIDS library; child care; consultative services for Pts and P in inland Northern California.
Conclusion. We present a unique public-private-academic model for health care services to people with HIV-related disorders.

W.B.P.260 THE ORGANIZATION OF AIDS SERVICES AT COOK COUNTY HOSPITAL, CHICAGO

Sherer, Renslow*; Katiyalis, S.*; Sable R.*; Cohen, M.**; Goth, L.**; Raab A.***; et. al.
* AIDS Prevention Service (CCHAPS) and Section of Retrovirology, Division of Infectious Disease; ** Division of General Medicine, Cook County Hospital; *** Cermak Health Services, Cook County Jail, U.S.A.

Objective. To implement a rational and comprehensive AIDS service organization for a diverse, multi-racial indigent population based in the only public hospital in Chicago.
Methods. Distinct expertise and service capability for persons with AIDS, HIV infection, and risk for HIV evolved in the Divisions of General Medicine and Infectious Disease and merged.
Results. Comprehensive service delivery begins with the AIDS Prevention Service, which provides bilingual, culturally sensitive, and confidential counseling and testing for 200+ persons at risk of HIV infection monthly. Targetted interventions for ivdus, minority women, Afro-Americans, Hispanics and prisoners are available by consultation in all clinical care areas. All new HIV-infected persons (20-30/mo) are referred for medical and immune evaluation and entry into therapy protocols. Seven weekly clinics serve 1000+ patients, 300+ of whom receive AZT. CCHAPS provides case management and volunteer support managers, as well as community-service links for residence, substance abuse care, home care, and others. The in-patient AIDS consultation service averages 20-30 patients throughout the hospital; a designated in-patient ward is planned. New initiatives include the women and children's clinic, providing medical, pediatric, ob-gyn, psychosocial, and on-site substance abuse services; and a planned 4-week out-patient detoxification program for HIV-positive active ivdus. Palliative home care for terminally ill PWAs is available.
Conclusions. Comprehensive services for persons with AIDS and HIV infection maximize client identification, early interventions for HIV prevention and treatment, access to medical care and experimental protocols, and appropriate psychosocial services and community referrals for primarily indigent and minority clients at Cook County Hospital. Collaborations with community-oriented agencies and the Cook County Jail Health Service enhance client services.

W.B.P.262 PRINCIPLES OF REHABILITATION OF PATIENTS WITH IMMUNODEFFICIENCIES

Sepiashvili, Revaz.
Immunological center, Tskhaltubo, George SSR, USSR.

Rehabilitation of immune system is a complex and versatile process which includes not only medical but professional, social and psychological aspects as well. It has its own peculiarities and regularities at different pathological processes constituting the base of a new field of knewledge in medical science, immunology in particular.

We have suggested the following main principles of rehabilitation of patients with immunodefficiencies:
I. Early beginning. 2. Prolongness of rehabilitetion measures.
3. Continuity and stageness of rehabilitation period:
a) I stage-specialized clinics or departments at the hospitals of common type; b) II stage-sanatorium, a specialized rehabilitation center at a resort; c) III stage-dispensaries and polyclinics at the clinics of scientific institutions or hospitals. 4. Complexity of carried out therapeutic procedures.

Usage of these principles in rehabilitation of patients with AIDS will promote lengthening of remission time, reducing the number of different exacerbations and as a result improving of the general state of the patients, heightening of their ability to work and reducing among those patients primary disablement and mortality.

W.B.P.264 REFERRAL PATTERNS IN A COMPREHENSIVE AIDS CLINIC

Lee, Shirley
The New York Hospital-Cornell Medical Center, U.S.A.

Objective: To assess referral patterns of physicians in a comprehensive AIDS clinic with regards to source and number of referrals.
Methods: Comprehensive services at the New York Hospital -Cornell Medical Center are provided by 4 primary physicians (2 infectious disease specialists, a hematologist and an internist) 2 psychiatrists, a nutritionist, a nurse practitioner, 2 social workers and assistance from rehabilitation medicine. Consultations requested by the primary physicians were recorded for all patients newly enrolled from August 1, 1988 to January 20, 1989.
Results: Of 76 patients enrolled, there were 106 initial referrals for 56 patients, and no referrals for 20 patients. Twenty-seven patients were referred to nutrition, 20 to psychiatry, 20 to dermatology, 10 to neurology, 8 to ophthalmology, 5 to surgery, 4 to pulmonary, 3 to gynecology, 2 to gastroenterology, 1 to rheumatology. No major differences were noted in number or type of referrals obtained by the primary physicians. There was a trend toward more referrals to nutrition, psychiatry and dermatology than other specialities. For nutrition and psychiatry referrals this may represent increased utilization of services immediately available. However, significant weight loss, cachexia and coping with terminal illness are major problems confronted by AIDS patients. The number of dermatology referrals reflected a need to accurately diagnose a variety of skin lesions. Referrals to neurology, opthalmology, pulmonary and gastroenterology were primarily for diagnostic procedures. Five patients were referred to surgery for operative procedures.
Conclusion: These referrals underscore the need for various specialists to participate in the care of AIDS patients. Physicians consult with other specialists who perform specific procedures in their field of expertise. Since AIDS is a multisystem disease collaboration among health care professionals is critical for the comprehensive evaluation and treatment of all AIDS related illness.

W.B.P.265 CLINICAL CARE AS PART OF INTEGRATED AIDS MANAGEMENT IN A ZAMBIAN RURAL COMMUNITY

Chela, Clement M.; Campbell, I.D.; Siankanga, Z.
The Salvation Army Chikankata Hospital, Mazabuka, Zambia.

Object. 1) to present an analysis of clinical symptomatology with a summary of major protocols for clinical management of hospital inpatients compared with patients in the home based care and prevention programme;
2) to analyse drug use and drug costs in the hospital and in the home based care setting.
Methods. A retrospective analysis of 200 inpatients and 200 patients in the home based care programme was done. The observed manifestations of AIDS are described, by organ systems, and treatment protocols are described, incorporating an analysis of drug use and cost on some of these patients.
Results. Tables and figures are presented showing main presenting symptoms found both in hospital and at home, and indicating that treatment protocols in the home setting are simpler and cheaper with respect to drug costs.
Conclusion. It is proposed that home based care and prevention with hospital intervention where required is the most practical and sustainable form of organisation for an integrated approach to management for a district rural hospital. Furthermore it is proposed that therapeutic constraints of certain kinds are acceptable in the context of "shared acceptability" by therapeutic teams, by patients, and by communities connected to the patients.

W.B.P.266 STUDY OF A SERIES OF 121 CONSECUTIVE AIDS PATIENTS.

CORRÊA-LIMA, M.B.*; SILVA, M.A.; BRANDÃO-MELLO, C.E.; LEITE, C. T.C.; HADDAD, L.R. & FONSECA, M.A.
Clínica Médica A, of the Universidade do Rio de Janeiro, UNI-RIO, Brasil.

The aim of the work was to study epidemiologically, Clinically and laboratorially a series of 121 consecutive AIDS patients, admitted to the Clínica Médica A of the Universidade do Rio de Janeiro, during the 1985-88 period.
METHODS: All the 121 consecutively admitted patients were studied trying to figure out the possible forms of transmission and therefore grouping them in the so called-risk groups. They were worked up as thoroughly as possible, either clinically as laboratorially.
RESULTS: Nineteen of the patients were women and 102 were men. Of the men 93 were homosexuals and 6 were bisexuals (one of them was also an intravenous drug addict. One was a hemophiliac and 2 received blood transfusions. Regarding the women 16 did receive blood transfusions, 1 was partner of a bisexual and 2 were drug addicts. The most frequent infections were systemic candidiasis (36), *P.carinii* pneumonia (28), tuberculosis (24), toxoplasmosis (12) and cryptosporidiosis (11). Five patients only had Kaposi's sarcoma.
CONCLUSION: Although the Clínica Médica A of UNI-RIO addmits both women and men (twice more women) 102 of the 121 patients (84,29%) were men. Homosexuals and bisexuals represented 97,05% of the total of males while 84,21% of the women probably got the infection through blood transfusions.

W.B.P.267 AIDS ISSUES FOR RURAL HOSPITALS IN U.S. FRONTIER AREAS

Carwein, Vicky; Berry, D.; University of Nevada, Las Vegas, Las Vegas, Nevada U.S.A.

Objective. To identify and assess the experiences rural frontier hospitals (under 50 beds) in 8 western states have had in the provision of care to HIV infected patients and to evaluate the preparedness of these hospitals to provide AIDS care via education and policy development.
Methods. A survey addressing the incidence of HIV infection in the hospital's service area, services provided to HIV infected patients, concerns of hospital employees regarding care of AIDS patients, provision of education and policy development was mailed to all frontier hospitals (N=108) in 8 states.
Results. Frontier hospitals in 7 states had had experience with HIV infected patients. Of the 46 hospitals who responded 13 had had experience with AIDS patients and 33 had not. Of the 13 with experience 9 provided care in the facility and 4 referred the patients. Suprisingly, employees in hospitals with experience expressed more concern about acquiring AIDS than those in hospitals without experience. Nurses Aids had the highest concern & 4 had refused to provide care. AIDS education consisted mainly of video programs, presentations by in-house staff and sending employees away to workshops. Major concerns expressed by the hospitals related to enforcing universal precautions, confidentiality of patient information, staff response, community acceptance & costs of care. Only 16 hospitals (36%) have AIDS policies.
Conclusion. The incidence of AIDS is increasing in rural areas throughout the U.S. Effectiveness of educational programs is questionable given the concern of staff in frontier hospitals with AIDS experience and education. Education and policies are essential to guide hospital personnel in the provision of AIDS care.

W.B.P.268 SEROPREVALENCE OF HIV, HERPES VIRUSES AND IMMUNOLOGIC ABNORMALITIES IN A GROUP OF IV DRUG ABUSERS

Pachucki, Constance T., Schaaff, D., Lentino, J., Schaefer, M. Dorus, W., Edward Hines V.A. Hospital, Hines, IL., U.S.A.

Objective: To determine the prevalence of infection with Epstein Barr Virus (EBV), Ctyomegalovirus (CMV), herpes simplex virus,(HSV), and HIV, and to correlate seroprevalence with immunologic abnormalities in a group of IV drug abusers.
Methods: HIV status was determined by ELISA and confirmed by Western Blot; viral serology was done by indirect immunofluorescence; lymphocyte subsets were done by flow cytometry.
Results: The seroprevalence of CMV, EBV, HSV, and HIV were respectively 74/104, 103/103, 76/103, and 4/111. No patient had evidence for clinical infection with any of these viruses. Of the EBV infections 26/103 had recent and 11/103 had chronic active infection. These 37 patients had higher percentages of lymphocytes but no difference in CD4/CD8 as compared with all others. Patients with recent or chronic active EBV infection with dual infection with CMV had higher CD8 and lower CD4/CD8 than either those without CMV infection or all others. A similar effect on the CD4/CD8 was not seen with the combination of recent or chronic active EBV infection and HSV infections.
Conclusion: Since dual infection with CMV and EBV may lower the CD4/CD8, use of this parameter as a prognostic factor or as an indicator for starting therapy in HIV positive patients should be done with caution.

W.B.P.269 PSYCHOSOCIAL ISSUES ASSOCIATED WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION IN A CITY HOSPITAL: EXPERIENCE OF THE MULTIDISCIPLINARY PATIENT CARE MEETING.

Cheung, Tony; Weissman, H; Montreuil A. Queens Hospital Center (QHC), Affiliation of the Long Island Jewish Medical Center, Jamaica, N.Y. 11432 USA

Objective. To survey the prevalence and range of psychosocial issues associated with HIV infection as discussed at QHC AIDS Team multidisciplinary meetings.

Methods. Records of the AIDS multidisciplinary patient care meetings at QHC from March, 1988 to October, 1988 were evaluated for psychosocial issues presented. These issues were broken down into 7 categories: denial, anxiety, depression, suicidal ideation, drug sue, psychosis and organicity.

Results. 108 patients were discussed at the patient care meetings. Of these, more than 80% had psychosocial difficulties. The age range was 20 to 64 (median=34). 74.1% were Black, 11.1% Hispanic and 7.4% were White and Haitian. 73.1% were IVDU, homosexual 11.1%, heterosexual 13.0% and blood transfusion related 2.8%. The psychosocial issues were: denial 7/108 (6.5%), anxiety/fear 18/108 (16.7%), depression 30/108 (27.8%), suicidal ideation 7/108 (6.5%), drug use 15/108 (13.9%), psychoses 13/108 (12.0%), organicity 20/108 (18.5%).

Conclusion. The data reflect the significant psychosocial morbidity associated with HIV disease. This study supports the importance of a multidisciplinary approach to dealing with HIV.

W.B.P.270 TRIAGE SYSTEM FOR POTENTIAL RESEARCH SUBJECTS INTO ACTIVE AIDS CLINICAL TRIALS.

DeGenova, V.; Mills, J.; Holland, R.; Feigal, D.; Volberding, Paul; Nash, M.
University of California, San Francisco, San Francisco General Hospital, U.S.A.

Objective: To facilitate accrual of potential research subjects by prescreening volunteers, collecting important laboratory and clinical data, identifying individuals and specific populations for a targeted recruitment effort.
Methods: A data base has been created to facilitate accrual into active AIDS clinical trials. Individuals interested in participating in clinical research are mailed a brief description of the prescreening process, a lay-language summary of clinical research methodology, and a preliminary registration form. After completion, the registration form is returned to the AIDS Triage Service. A research nurse then contacts the individual to complete a research profile which is entered into the data base. The profile includes dates and quantitative values of most recent p24 antigen (p24ag), Beta-2 microglobulin, T-lymphocyte counts, as well as the date of diagnosis of HIV-related events and treatments. The data is used to preliminarily screen subjects by comparing trial inclusion/exclusion criteria to the population in the data base. Continuing data base participation requires research profile updating every three months.
Results: A total of 659 subjects are currently in the data base; 188 asymptomatic (CDC II, III), 241 ARC (CDC IVA, IVC2), and 230 AIDS (CDC IVB, IVC1, IVD, IVE). Subjects have the following CD4+ lymphocyte count and p24 antigen status.

	CD4+ Lymphocytes				
	</=200	201 - 400	>400	Unk	Total
p24ag +	53(45%)*	30(42%)*	11(26%)*	5	99
p24ag -	65(55%)*	42(58%)*	31(74%)*	3	141
p24ag unk	149	85	84	101	419
TOTAL	267	157	126	109	659

*Represents % of subjects who know their antigen status

Conclusions: A data base of potential research subjects containing clinical and laboratory data enables targeted research recruitment and preliminary screening of eligibility criteria.

W.B.P.271 ASSESSMENT OF THE NEEDS OF A HIV ACUTE/CHRONIC LEVEL CARE UNIT

SCHEIB,Rochelle; MARKS,S.; BRADLEY,O.;DESROCHES,A.; MORGAN,B.; BAER,J.; et al., Lemuel Shattuck Hospital,Tufts U. Schl. of Med., Boston,MA,USA.

To date the traditional medical model of acute and chronic level care has been used to provide services to the affected HIV population. There has been increasing demand for chronic level care beds to alleviate hospital acute care bed use. This study presents data from the Lemuel Shattuck Hospital HIV Unit which provides medical care on both the acute and chronic level.Objective.This review is to assess consultative needs of HIV long term care to aid in future planning. Methods.Data compiled by chart review of individuals admitted from June 30, 1987 through Nov. 1,1988.Results.Demographics 60% white, 30% black, 10% hispanic.Risks factors 60% Homosexual/Bisexual, 28% IVDA, 12% other.Length of stay (1 day - 285 days), average June 87-June 88; (52 days) July 88-Nov. 88,(36.5 days).63 individuals received care.80% of admissions were for initial chronic level care with the primary HIV disease necessitating chronic care being 70% neurologic; 24% infectious; 6% neoplastic.68% chronic level patients required acute level medical management.30% of all patients required acute psychiatric intervention during hospitalization (psychotic, suicidal ideation).20% of patients had an extended hospitalization due to lack of lower care facilities i.e. supervised housing. We conclude that in the future planning of HIV long term care these acute medical needs as well as significant neurologic and psychiatric services be addressed.Cost per hospital patient day is $810,thus the economic burden to even chronic level care facilities is exacerbated by lack of lesser care facilities.

W.B.P.272 THE ROLE OF THE PHARMACIST IN THE HIV TEAM

Fitt S.M.*, Bunn R.J.*, McManus T.**, and Moxham J.***
*Pharmacy Department, Dulwich Hospital, **Dept. of G.U. Medicine, ***Dept. of Thoracic Medicine, King's College Hospital, London, UK

Objective: To discuss the role of the pharmacist in the management of HIV and AIDS patients.

Method: In April, 1988 a pharmacist was appointed to the team managing HIV and AIDS patients in Camberwell Health Authority.

Results: The appointment has led to a large pharmaceutical input into the management of this group of patients.

The main areas of involvement are:-

(1) A clinical attachment to the team looking after HIV and AIDS patients.
(2) Provision of advice and information on new drugs, drug interactions, adverse drug reactions and establishment and maintenance of an AIDS data base.
(3) Surveillance of drug usage to provide costing predictions for budgeting purposes.
(4) Education of clinicians, patients and health care staff on drug related subjects.
(5) Co-ordination of clinical studies involving research into new drugs.

Conclusion: As the management of HIV and AIDS patients often involves complicated drug therapy, the pharmacist is the most appropriate person to monitor and advise on this important aspect of care.

W.B.P.273 CAUSES OF HOSPITALIZATIONS FOLLOWING AIDS DIAGNOSIS IN A POPULATION-BASED COHORT.

Hulman Sharon J.; Modesitt,S.; Klockner,R.; Bennett,D.; Fleming,D. Oregon Health Division, Portland, Oregon, U.S.A.

Objective. To accurately determine causes of hospitalizations after an AIDS diagnosis by following all cases in a statewide population-based cohort.
Methods. We follow all AIDS cases detected by active AIDS surveillance in Oregon who remain in the state for follow-up medical care. At six month intervals, we review each patient's medical record and abstract information about every hospitalization requiring at least an overnight stay.
Results. Records were available for 381 (94%) of the 407 Oregon AIDS cases diagnosed between 1/01/81 and 6/30/88. Of these, 59 (15%) died during the hospitalization in which AIDS was diagnosed. Following their diagnosis, the remaining 322 patients were hospitalized 523 times during 3,965 case-months of observation. For 240 (46%) subsequent admissions, the primary discharge diagnosis was not linked to an opportunistic condition diagnostic of AIDS (OC). The most common causes for these admissions included fluid and electrolyte disorders (12%), anemia (7.5%), and fever of unknown origin (7%). For 283 (54%) subsequent admissions, an OC was linked to a primary discharge diagnosis. 153 of these subsequent admissions were due to the OC that resulted in the patient's initial diagnosis. Compared to the OC's that resulted in the diagnosis of AIDS, OC's causing subsequent hospitalizations were less likely to be *P. carinii* pneumonia (PCP) (78% vs. 36%, p<.001) and more likely to be lymphoma (4% vs 13%, p=.001), Kaposi's sarcoma (2% vs 13%, p<.001), and atypical mycobateria (1% vs 8%, p<.001). Certain OC's leading to hospitalization were more likely to develop only after a diagnosis of AIDS had been made. These included candidiasis (present in 14% of patients at AIDS diagnosis, causing hospitalizations in 29% of others subsequently); cytomegalovirus (3% at dx, 7% of others subsequently); atypical mycobacterial infection (3% at dx, 6% of others subsequently) and M. tuberculosis (1% at dx, 3% of others subsequently).
Conclusions. Although PCP most commonly leads to an AIDS diagnosis, other OC's and other illnesses are more common causes for subsequent hospitalizations. Strategies to reduce inpatient days may be more effective if they are general rather than disease specific.

W.B.P.274 TUBERCULIN SKIN TESTING IN HIV INFECTED PERSONS.

C. Banerjee, Gale Cromwell, P. Furth, University of Maryland Medical School, Baltimore, Maryland, USA.

HIV infection is a probable risk factor for reactivation of latent M.Tb. but there is little data on the value of tuberculin skin testing in HIV infected persons. We prospectively evaluated the diagnostic utility of 1 and 2 step PPDs, anergy panels (mumps and candida) and chest x-rays to identify latent M.Tb. infection in 58 HIV infected persons (19 with AIDS, 39 male/19 female, age range 20-50, 47 black, 11 white, 41 IVDA, 12 homosexual, 5 heterosexual). Results of skin tests were correlated with mean T4 cell count and Hgb. Control group: inner city residents matched by age, race and zipcode who received a 1 Step PPD in a pre-employment physical.

	Number of Persons	Mean T4 Cells*	Mean HgB*	Abn. CXR
1 Step PPD +	8/58 (16%)	329	13.5	1
1 Step PPD -	50/58 (86%)	244	13.0	0
Anergic	42/50 (84%)	314	11.8	0
2 Step PPD -	18/18 (100%)	115	12.0	0
Control	28/185 (15%)	–	–	1

*No significant difference between groups by student t-Tests.

PPD testing can be diagnostic even when T4 count < 350; neither CXR or 2 Step PPD added diagnostic information in this group; prevalence of positive PPDs in HIV infected persons was similar to control group; high prevalence of anergy makes evaluation of negative PPD difficult. All persons will be followed prospectively for development of symptomatic M.Tb. infection.

Immunomodulateurs
Immunomodulators

W.B.P.275 CELLULAR PHARMACOLOGY AND CLINICAL PHARMACOKINETICS OF 2',3'-DIDEOXYADENOSINE AND 2',3'-DIDEOXYINOSINE

Hartman, Neil R.; Yarchoan, R.; Ahluwalia, G.S.; Kelley, J.A.; Broder, S.; Johns, D.G. National Cancer Institute, Bethesda, MD, USA.

Objective. To study the cellular pharmacology and the clinical pharmacokinetics of 2',3'-dideoxyadenosine (ddA) and 2',3'-dideoxyinosine (ddI), anti-HIV agents with low *in vitro* cytotoxicity.
Methods. Samples from AIDS or ARC patients receiving oral or IV ddA or ddI are analyzed by reversed-phase HPLC. Phosphorylation of ddA and ddI are studied in human T-cell lines and analyzed by anion-exchange HPLC.
Results. Since ddA is rapidly deaminated to ddI by adenosine deaminase, only ddI is detected in plasma of patients receiving ddA. Doses of ddI from 0.2 to 1.6 mg/kg produce peak plasma levels of 0.6 to 5 µM respectively, within the range of effectiveness seen *in vitro* (ED_{50} 2-5 µM vs. HIV in the ATH8 test system). ddI has a plasma half life of approximately 35 minutes. This may not be representative of the biological effect of the compound, however, as both ddA and ddI are converted intracellularly to the active species ddATP which has an intracellular half-life of up to 24 hours. Because of the acid lability of ddI, antacids are given prior to oral administration; in this form oral bioavailability is about 35%. Approximately 20% of the administered dose of ddI is excreted unchanged in the urine. ddI can be detected in the CSF of patients receiving both ddA and ddI in the range of 12 to 27% that of the simultaneous plasma concentration.
Conclusion. Plasma levels equal to those found to be effective *in vitro* are achievable in patients given ddI IV or orally. The long intracellular half-life of ddATP may allow a sustained anti-HIV effect with intermittent dosing.

W.B.P.276 IMMUNOSTIMULATION COMME UN SUPPORT CHEZ SIDA - MALADES ET HIV-SEROPOSITIVES

Kornaszewski W[x].Lurhuma Z.Lutete K.Mbula M.Skotnicki A.[xx]
[x]Université de Kinshasa,Zaïre,Departement d'HematologieCracovie,Pologne.[xx]

Objectif.Présenter les 3 ans du traitement des SIDA et HIV-séro+. par l'immunostimulation utilisée dans le but d'activisation physilogique des mécanismes de défense immunitaire surtout par la production d'interferon et d'interleukine II- endogéne,en respectant des résultats précédents positifs de cette actión dans certaines maladies infectieuses.
Méthodes, L'action des immunostimulateurs comme un support thérapeutique avec du traitement obligatoires des infections opportunistes,chez SIDA-malades et comme prophylaxie chez HIV-sero+.,était observé dans le milieu africain à la base des critéres cliniques et laboratoires divers.
Résultats, Parmis plusieurs immunostimulateurs,le plus efficace se revelé des extraits du Thumus : THYMEX L à I50 Mg ou TFX-Thymomodulin à 20Mg données IM 3 x par semaine,pendant 2 mois et répétées dans les cures 3 - 4 fois par an.

SONT VIVANTS PLUS QUE:			3 ANS	2 ANS	1 AN	DECEDES
SIDA-Malades	avec immunostimulation	/N 51/	6	6	20	19
	sans immunostimulation	/N 45/	0	0	6	39
HIV-Séro +	avec immunostimulation	/N31/	8	10	12	1
	sans immunostimulation	/N 12/	0	2	5	5

Conlusions: L'immunostimulation ne donne pas des effets secondaires. Elle a prolongé la vie des SIDA-malades en condition que on a traité des infections opport.Elle est moins efficace chez les sujets epuisés et cachectiques.Chez HIV-sero+;elle améliore l'état physique et psychique, protége contre les infections opport.et fraine leur évolution.

W.B.P.277 DIETHYLDITHIOCARBAMATE INHIBITS THE PROGRESSION OF HIV INFECTION. RESULTS OF A PROSPECTIVE RANDOMIZED CLINICAL STUDY

Dietrich, Manfred et al.
Bernhard-Nocht-Institute for Tropical Medicine, Clinical Department ; AK St. Georg, Dermatology ; AK Ochsenzoll, Neurology ; Hamburg; Forschungsinstitut Borstel, Germany, Institut Mérieux, Leimen, Germany.

Objective. Diethyldithiocarbamate (DTC) is a chelating agent with in vitro and in vivo influence on the production of HIV. Recently, J.M. Lang et al. (Lancet, Sept. 24th, 1988, 702-705) presented their data of a 4-months treatment study with positive response both in improvement of patients and increase in T4-cells. In 1986, we initiated a study in order to evaluate the efficacy of DTC in patients with HIV infection, Walter Reed 2-4.
Methods . 60 patients were randomized to DTC 5 mg/kg i.v., DTC 10 mg/kg orally once a week for a period of 6 months. Both groups were placebo-controlled.
Results . The results were evaluated by the following parameters: progression to a higher CDC classification, progression to AIDS, changes in immunological parameters. I.v. application resulted in a significantly higher progression of the CDC classification in the placebo group compared to DTC ($p< 0.05$). The oral application showed the same trend (7 placebo patients progressed in contrast to 3 of DTC). In the DTC i.v. group, none progressed to AIDS during treatment in contrast to 6 placebo patients (Log Rank test $p< 0.05$). The interleukin-1 production and interleukin-2 receptor presenting monocytes were significantly different at the end of the treatment. The ratio of T4-cells before and after treatment was significantly different between placebo and DTC treated patients.
Conclusion. DTC is effective to slow down the progression of HIV infection in patients, WR classification 2-4. It seems not to be able to increase the absolute number of T4-cells.

W.B.P.278 TREATMENT OF HIV-INFECTED PATIENTS WITH D-PENICILLAMIN - TENTATIVE CLINICAL AND IMMUNOLOGICAL RESULTS -

Höffken,Gert*,Bieniek,B.*,Ludwig,W.-D.*,Lode,H.*, Mielke,H.**,Zorr,B.***,
*Med.Clinic of Klinikum Steglitz,**Institute for clinical microbiology and *** Institute for clinical and experimental virology of FU Berlin,F.R.G.

Objective. To evaluate the compatability and clinical, immunological and virological efficacy of D-Penicillamin - before, during and after a 6-week therapy in HIV-1 seropositive patients(pts).
Methods. On-going prospective randomised placebo-controlled study. test criteria: lymphocyte-subsets (CD3+,CD4+,CD8+, CD8+/Leu7+, CD4+/Leu8+),lymphocyte-proliferation test (LPT) after PWM and tetanus-toxoid-antigen stimulation), p24 antigen (Dupont Co.) and HIV-cultivation on primary blood lymphocytes.
Results. Until now 17 male pts (15 homosexual men, 1 i.v. drug-user, age 22 to 52 y., CDC-stage II 4, III 6, IV 6) are randomised to receive either placebo (n=8) or D-Pen (escalating dosing: 600,1200,2100 mg/d) for 6 weeks orally. The side-effects were generally mild. But in 2 pts therapy was discontinued because of drug adverse reactions (fever, diarrhea/vomiting). No stage progression could be seen. The first analysis showed a slight reduction of leukocytes and granulocytes during therapy. Furthermore, before/at the end of/6 weeks after therapy with D-Pen (placebo): leukocytes: 5667/5182/6040 G/l (6417/5800/6300), creatinine: 82/86/80 umol/l (82/74/81), protein/day in urine: 0.7/0.4 g/l (0.3/0.1), CD4+ lymphocytes: 486/445/575* /ul (404/470/507), CD8+: 824/824/1230* /ul (800/866/865), CD8+/Leu7+: 358/387/504 /ul (413/387/299), CD4+/Leu8+: 600/251*/384* /ul (630/436/253).(* Wilcoxon test p<0.05). No change was seen in the LPT: PWM 14/9/13 E3 cpm (20/18/17 E3 cpm). P24 antigen could only be detected in three pts. before therapy and seems to be of limited value for monitoring.

Conclusions. First results show a good compatibility of D-Pen in HIV-infected patients; the relevance of the observed alterations in the lymphocyte subsets is not clear yet.

W.B.P.279 RECOVERY OF DELAYED-TYPE HYPERSENSITIVITY (DTH) IN PATIENTS WITH AIDS-RELATED COMPLEX (ARC) IN RANDOMIZED TRIAL OF IMREG-1

Piala, Milan*, Cone,LA*and Sayre,J**. *Eisenhower Medical Center, Rancho Mirage,CA,USA, **UCLA School of Public Health, Los Angeles, CA USA.

Objective. IMREG-1, an immunoregulator containing tyrosine-glycine(-glycine) enhances multiple immune functions. We have studied IMREG-1 in patients with ARC or Kaposi's sarcoma (KS) regarding efficacy and immunoenhancing effects.
Methods. Forty anergic patients in a placebo controlled, randomized, 6 month trial of IMREG-1 and 6 other patients in Southern California were tested every 2-3 months with tetanus toxoid (TT) during the trial and with TT and candida (CA) during compassionate IMREG-1 administration after the trial. The following were analyzed: (a) re efficacy 29 patients (2 with KS and 27 with ARC) in the IMREG group and 11 patients (all ARC) in the placebo group; (b) re DTH 22 and 7 patients respectively. The 2 groups were comparable with respect to baseline characteristics and the number of dropouts.
Results. In the IMREG group, 9(41%) became reactive to TT after an average of 280 days whereas, in the placebo group, 1(14%) recovered DTH after 437 days. Six(27%) IMREG-1 treated patients and 2(29%) from the placebo group became responsive to CA in the compassionate phase. Two cases of Pneumocystis carinii pneumonia (PCP) occurred in the IMREG group during 11,621 person-days, and 5 opportunistic infections (2 PCP's, 2 wasting syndromes, and 1 dementia) developed in the placebo group during 3,914 person-days (rates 0.17 (IMREG)vs 1.27 (placebo) infections per 1000 person-days, relative risk = 7.47, P=0.003).
Conclusions. Forty-one percent patients recovered DTH to TT after an average of 280 days of IMREG-1 treatment. Patients initially in the IMREG-1 group had better clinical outcome during and after the trial.

W.B.P.280 EFFECT OF ISOPRINOSINE ON HIV-ANTIGENAMIA

Lars S.Teglbjerg*, S.Kroon**, T.Moestrup***, B.G.Hansson***, B.F.Vestergaard**** and Scandinavian Isoprinosine Study Group.
*Hvidovre Hospital,Denmark,**Bispebjerg Hospital, Denmark,
Malmö Almänna Sjukhus,Sweden,* Statens Seruminstitut,Denmark.

Objective:
To evaluate the effect of isoprinosine on HIV-antigen levels.

Methods:
A multicentre, double-blind placebo controlled study of isoprinosine was carried out in 21 clinical centers in Denmark and Sweden.
Eight-hundred sixty-six patients received treatment for 6 months with either isoprinosine 3 gram a day or matching placebo.
The study population included anti-HIV-positive patients without AIDS. The patients were block randomized according to the number of CD4+ lymphocytes.
Serum samples were collected at entry and during treatment and stored frozen for later antigen detection.

Results:
The data will be presented and correlated with clinical and other immunological markers of disease progression.

W.B.P.281 Induction of T Lymphocyte-Related functions by Imuthiol^{R} through down regulation of prostaglandins secretion by moncytes/macrophages.

Mossalayi, M. Djavad , Dalloul, A.H, Bertho, J.M. and Debré, P.
CHU Pitié-Salpêtrière, Paris, France.

Objectif. Description of immunostimulating effect of Imuthiol® (sodium ditiocarb, DTC).

Methods. PBL, their adherent subsets and T cells were assayed for their capacity to produce IL2 and their mitogenic responses to PHA with/without 10^{-7} mg/ml Imuthiol®. The effect of Imuthiol on IL1 and PGE 2 secretion by adherent cells was also evaluated using thymocytes assay and RIA method respectively.

Results. Imuthiol® increased proliferative responses of PBL to PHA as well as their ability to secrete IL2. This stimulating activity was not seen when these cells were depleted from their adherent cells. In addition Imuthiol displayed high inhibitory effect on PGE 2 production by these cells but IL1 levels remained unchanged.

Conclusion. Imuthiol enhanced most T cell related functions through its ability to down regulate monocytes/macrophages derived PGE2 as these molecules were known to inhibit most T cell related functions and specially helper activities.

W.B.P.282 A MULTICENTER RANDOMIZED DOUBLE-BLIND PLACEBO CONTROLLED DOSE-RESPONSE TRIAL OF LF 1695 IN P24-ANTIGEN SEROPOSITIVE PATIENTS

Rosé, René* ; Kienzler, J.L.** ; Dormont, D.*** ; Fleury, H.**** ; Lang, J.M.***** ; Mouton, Y.****** and al.
* Scientific coordinator of the trial, Hôpital Militaire Begin, Saint-Mandé, France ; ** Monitor of the trial, Centre de Recherche, Laboratoires Fournier, Dijon, France ; *** CRSSA, CEA, Fontenay aux Roses, France ; **** Hôpital Pellegrin, Bordeaux, France ; ***** Hôpital Hautepierre, Strasbourg, France ; ****** Centre Hospitalier, Tourcoing, France.

Objective. LF 1695 is a synthetic biological response modifier with immunorestoring and enhancing effects in animal as well as in human in-vitro and in-vivo. He has also shown in some in-vitro experiments an inhibitory effects on HIV-1 replication. On the basis of these findings, we conducted a clinical trial to evaluate the virological, immunological and clinical impact of LF 1695 in P24-antigen seropositive patients.
Methods. A multicenter randomized, double-blind, placebo-controlled, dose-response trial is in progress in 60 HIV infected patients (CDC groups II to IV), with a P24-antigen level higher than twice the cut-off level (Abbott). Patients receive twice a day a placebo or 120 mg or 240 mg of LF 1695 in capsules for three months. Parameters measured are reverse transcriptase level, P24-antigen, T-cell antigens expression, serum immunoglobulins and β2-microglobulin, clinical evolution and routine haematological and biochemical tests.
Results. Forty seven of the 60 expected patients have actually entered the trial.
Conclusion. Final results of this ongoing trial will be presented and discussed.

W.B.P.283 AS 101, A NEW IMMUNOMODULATING COMPOUND IN THE TREATMENT OF AIDS.

J.Ph. LAPORTE*, J. LEBAS*, G.GONZALES*, M.MEYOHAS*, B.SREDNI**, A. NAJMAN* et al.
* St Antoine Cooperative Group on AIDS 75012 PARIS FRANCE
** Bar Ilan University , Ramat Gan ISRAEL

AS 101 (Nature 1987,330:173-176) was administered IV 3 times a week at the dosage of 5 mg/m^2 on AIDS patients. 44 patients entered the study (41 M, 3 F) median of age 27 (22-61) years.CDC staging : stage IV all of them (C:30 patients, D:14, A:3, B:5). HIV antigenemia was positive in 50 % of the cases. Most patients were included because of toxicity and/or failure of AZT (80 %). 31 patients were evaluable. Median duration of therapy was 4,5 months (1.5-14). Results : Clinical improvement occured in 54 % of the cases with weight gain and improvement of Karnosky status. However clinical improvement was not sustained in time : median duration 3 months (1,8). In 3/8 patients Kaposi Sarcoma improvement of specific lesions was transiently observed during a median of 2 months. Biological : In 4 cases we observed disappearance of cytopenia. HIV culture was performed in 18 patients and positive in 14. HIV antigenemia was positive in 17 cases, negative in 14 cases. We never observed negativation of antigenemia. T4 level increased (2 to 9 fold) in 30 % of patients and T4/T8 ratio increased in 48 % of cases. Level of IL2 increased in 4/8 tested patients. Toxicity was moderate - garlic smell of the breath (59 %) - hair lightening (50 %) - transient exanthema (20 %) at the beginning of therapy . In 3 cases, AS 101 was stopped because of recurrence of cutaneous rash. Conclusion : AS 101 was safe and well tolerated. Positive results occured in half on AIDS patients, however theses effects, in our serie, are not always sustained. Combination therapy with antivirals should be tested.

W.B.P.284 Enhancement of T cell growth, in HIV+ patients treated with Ditiocarb (IMUTHIOL®) : evidence for monocyte involvement.

Dalloul, Ali. H. Mossalayi, M.D. ; Kirstetter, M. ; Debré P.
CHU Pitié-Salpêtrière, 91 Bd de l'Hôpital, 75013 Paris, France.

Objective. Testing the in-vivo immunostimulating effect of Imuthiol® (sodium ditiocarb, DTC)

Methods. 48 HIV+ patients were randomized into two groups : 22 had no treatment, and 26 were given Imuthiol® (10 mg/kg weekly for 8 weeks).
Blood was collected, and mononuclear cells assayed for the following : T colony formation in agar, and ^{3}H thymidine uptake, in response to PHA and rIL2.
IL2 synthesis by T cells in response to PHA, was evaluated on CTLL2 line.

Results. IL2 synthesis was comparable in both groups. In contrast, the treated group showed significantly higher T-CFC, and T cell proliferation than the untreated one ($0.01 < p < 0.05$), when PBL were assayed. This difference was abolished when E+ (monocyte depleted) cells were tested for the same functions.

Conclusions. IMUTHIOL® treated HIV+ patients, have better T-cell-related functions than untreated ones. Our data provide evidence that monocyte population is the target for ditiocarb-mediated effect, and corroborate other findings that ditiocarb down regulates monocyte-derived PGE2 synthesis.

W.B.P.285 SURVIVAL RATE IN AIDS PATIENTS FOLLOWING TRANSFUSION THERAPY WITH CR1 ENRICHED ERYTHROCYTES

Sulzberger, Judith; Inada, Y.; McKinley, G.F.; Ikegami, H.; Senderowicz, A. and Lange M. et al
St.Luke's-Roosevet Hospital Center, Columbia University, New York, N.Y. USA

Objective. Erythrocyte C3b recptors (CR1) play a crucial role in the inactivation and clearance of circulating immune complexes. We previously reported the induction of temporary clinical remission in AIDS patients (Pt) following transfusion (Tx) of CR1 enriched packed erythrocytes (PRC). We report our data using this therapy in AIDS patients with primary PCP infection.
Methods. Two groups of Pt were enrolled. In both primary PCP had been diagnosed within 90 days prior to the onset of Tx. Group I (N=21) received 2-4 units of PRC at the end of initial PCP therapy. This group received further Tx only if new opportunistic infections arose or if the Hct fell below 30%. Group II (N=9) received 2-4 units of PRC regularly every 8 weeks. All Pt in group II were on same form of PCP prophylaxis. None of Pt in Group I or II took Zidovudine (AZT). All Pt were monitored monthly. A group of 9 Pt with primary PCP receiving neither AZT or Tx served as retrospective controls.
Results. Survival rate at 52 weeks for group I was 62% (13/21), and for group II was 78% (7/9). Of those group II Pt surviving >1 year, 5/7 remain alive at 15-22 months from the onset of therapy, 3 of which remain well and without any new opportunistic infection at present time (Ave.15 months). In the control group the survival time at 52 weeks was 22 % (2/9).
Conclusion. Our study appears to indicate that use of timed Tx of CR1 enriched PRC with PCP prophylaxis given to AIDS-PCP Pt prolongs life expectancy and disease free interval. We feel this form of therapy may be used as an alternative for those Pt not tolerating AZT or in conjunction with AZT.

W.B.P.286 PEPTIDE T PHASE I STUDY:IMMUNO/VIROLOGIC RESULTS

Goodwin, F.K.*, Heseltine, Peter**, Bridge, T.P.*, Martin, J.**, and Leedom, J.M.**
*National Institute of Mental Health, Bethesda, MD.,
**University of Southern California, Los Angeles, CA., U.S.A.

Objective. To evaluate the toxicity and possible response measures to Peptide T (D-ala-1-peptide-T-amide), a homologue of VIP and gp-120, and gp-120 receptor blocker. Methods. In this ongoing study, 9 AIDS and 5 ARC patients have received IV Peptide T (dose range:.06-.8mg/kg/day) or intranasal (25 mg/day). For 12 weeks,4 AIDS and 5 ARC patients had fixed doses; the others received escalating doses for 30 days. No other antiviral agents were given. Results. Pruritis led to drug withdrawal in 1 patient. No other toxicity was observed. Return of skin test response was seen in 3 anergic patients:1 to tetanus and Old TB; 2 to ≤ 2 antigens. T4 counts rose and p24 level fell in 1 patient with p24>50 pg/ml; returning to baseline off drug. After 12 weeks on drug, in vitro mitogen response to tetanus increased in 5/6 and to PHA in 2/5 patients; mean weight gain was 2 kg., and POMS increased by 1 S.D.in 6/9. Conclusion. Peptide T was well tolerated for 12 weeks, with increases in body weight and well-being noted. Preliminary results indicate that these measures and mitogen, skin test reaction, and p24 levels may be useful efficacy parameters for Phase II testing of Peptide T.

W.B.P.287 DOSE RESPONSE STUDY OF DAILY DIETHYLDITHIOCARBAMATE (DTC) IN PATIENTS WITH ARC/AIDS

Petersen, Eskild A.*; Hersh, E.*; Fish, D.*; Kaplan, C.*; Gorman, R.*; and Darragh, M.*
*Department of Internal Medicine, University of Arizona, Tucson, AZ, USA.

Objective. Daily DTC at a dose of 200-600 mg/kg (equivalent to 600-1800 mg/m2 human) is clearly effective in treating mice infected with LP-BM5. Weekly dosage is less so. Thus, this study was designed to determine the toxicity effect of DTC given daily to patients with ARC or AIDS.
Methods. Patients with AIDS or ARC were given daily DTC in 4 groups. Group 1, 100 mg/m2 per day; Group 2, 200 mg/m2 per day; Group 3, 400 mg/m2 per day and Group 4, 600 mg/m2. Toxicity, pharmacokinetics and effect on symptomatology and immune functions were studied following one month of treatment.
Results. The 100 mg/m2 dose was well tolerated by all subjects. At 200 mg/m2 two patients had gastrointestinal disturbances and one patient had a mild CNS reaction. At 400 mg/m2 all patients experienced extreme fatigue, inability to concentrate and a loss of memory. In addition 1 patient developed a rash. At 600 mg/m2 4-5 patients also experienced extreme fatigue, agitated sleep patterns, mild anorexia and 1 patient experienced hallucinations. DTC did not affect CD4, CD8 or total T cells.
Conclusion. DTC in its current formulation cannot be given to patients in therapeutic equivalent doses which were found effective in the murine AIDS model. Side effects are mainly central nervous system and gastrointestinal tract related. Determination of the mode of action of DTC should provide the basis for molecular alteration reducing its human toxicity profile.

W.B.P.288 The Effect of Isoprinosine ® (inosine pranobex) (IP) in HIV-Seropositive Patients with Low Risk for Developing AIDS.

Loveless M.O., Robins, D.S. and the US/UK Isoprinosine Clinical Investigators' Group. U.S.A.

Laboratory studies have suggested modest improvements in mitrogen response and IL-2 production in peripheral blood lymphocytes from HIV-infected patients treated with IP. Small scale studies of HIV-patients treated with IP have demonstrated increases in T-helper cell counts, increased NK-cell activity, and decreased CMV shedding in semen. To determine whether IP could delay the progression of disease in HIV-seropositive male patients, 696 patients with CD4+ cell counts between 200 and 400 per cu.mm. were enrolled in a multicenter US/UK prospective double-blind randomized trial to receive either IP 4.0 gm daily or placebo. Patients were followed at monthly intervals for six months of blinded study, then all patients were allowed to receive IP 4.0 gm. per day for six months of open-label therapy. The demographics of each group were similar except that more patients in the IP group had experienced a sexual exposure with a person later known to develop AIDS. 101 patients were discontinued from the double-blind portion leaving 595 evaluable patients. There were no significant differences in clinical endpoints (development of AIDS, or CD4+ cells <200 and 2 HIV-related signs or symptoms) between the IP and placebo groups. CD4+ lymphocyte counts were significantly lower in the IP treated patients during the first two months in the U.S. study centers, but this difference disappeared by six months. There was no signifcant toxicity of the drug; mild hyperuricemia was noted in the IP group. IP was not effective in delaying the progression of HIV-disease or decreasing the severity of incidence of lesser opportunistic infections and/or conditions in HIV-positive patients with CD4+ lymphocyte counts between 200 and 400 per cu. mm.

W.B.P.289 EFFECT OF ORAL DEXTRAN SULFATE ON THE MOUSE INTESTINE.

Wells, Carol L.; Erlandsen, S.L.; Rhame, F.S.
University of Minnesota, Minneapolis, Minnesota, USA.

Objective. Because oral dextran sulfate causes severe diarrhea in AIDS patients (typically occuring after several weeks of therapy), we investigated the effect of oral dextran sulfate on mice.
Methods. Dextran sulfate (7000-8000 MW, 17-20% sulfur) was placed in the drinking water (8 mg/ml) of Swiss Webster mice. Intestinal flora and histology were examined over various intervals.
Results. Light microscopy of ileal and colonic segments indicated that oral dextran (38 days) caused shortening and blunting of villi, as well as a mild dysplasia of epithelial cells. Gram stains of intestinal contents of treated mice showed numerous large gram-positive bacilli resembling *Clostridia* or *Bacillus* species; similar morphologies were not observed in control mice. Dextran treated mice also had a leukocytic infiltrate in the intestinal lumen (Wright-Giemsa stains) and an overgrowth of facultative gram-negative bacilli (quantitative culture of intestinal segments on MacConkey agar).

Experiment	Treatment	Days	No. of mice	Tissue segment	Avg±SD $\log_{10}$ viable facultative gram-negative bacilli/gram
1	H_2O	38	4	cecum	3.4 ± 0.5
	dextran	38	4	cecum	5.8 ± 0.4[a]
2	H_2O	21[b]	3	ileum	3.3 ± 0.7
	dextran	21	3	ileum	5.5 ± 1.4
	H_2O	21	3	colon	3.2 ± 0.7
	dextran	21	3	colon	7.5 ± 1.5[c]

a. Significantly increased compared to control, p = 0.006.
b. Mice sacrificed at 7 days had no differences in the numbers of viable ileal or colonic bacteria.
c. Significantly increased compared to control, p = 0.041.

Conclusion. Oral dextran was associated with qualitative and quantitative changes in the intestinal flora, as well as histological alterations of the mouse intestinal mucosa.

W.B.P.290 IMMUNOLOGICAL DATA FROM AN ISOPRINOSINE (IMUNOVIR) DOUBLE BLIND, PLACEBO CONTROLLED STUDY

Seeberg, Bjørn*, Dickmeiss, E.' and Skinhøj, P.*
*Department of Infectious Diseases and 'Tissuetyping lab., University Hospital (Rigshospitalet), Copenhagen, Denmark.

Objective: To evaluate possible differencies between baseline, midway and final outcome values for mitogen-induced lymphocyte proliferation on 85 HIV-infected persons without AIDS. Theese persons are a one-center-subgroup of Scandinavian Isoprinosin double blind, placebo-controlled study.

Methods: PHA and PWM was used a stimulant for lymphocytes before, during and at end-point of 6 months treatment-period.

Results: Baseline values were similar for treatment/placebo-group, PWM at 27.5%, and PHA at 68.5% relative value. At mid-point and end-point of treatment-period only a positive trend for the active treatment group was observed, but no significant difference was reached.
Conclusion: The results of mitogen-stimulated lymphocyte proliferation during Isoprinosin treatment are not strong predictors of the clinical benefit found as reported elsewhere.

W.B.P.291 INTRAVENOUS IMMUNOGLOBULINS IN ADULTS WITH ARC AND WR5 - A DOUBLE BLIND LONGITUDINAL TRIAL

Matthias Schrappe-Bächer; H.Rasokat; S.Degenhardt; G.Fätkenheuer; B.Salzberger and the ARC-IVIG-Study-Group Cologne/Berne (Depts. of Internal Medicine II, Pathology, Dermatology, Virology, Med. Microbiology and Biostatistics, Univ. of Cologne, FRG, Central Laboratory Swiss Red Cross, Berne, Switzerland)

Objective: Evaluation of the influence of Intravenous Immunoglobuline (IVIG) on T4-cell-count and clinical status in advanced HIV 1-infection.
Methods: Inclusion-criteria were (1) < 400 T4-cells/µl and (2) oral thrush or cutaneous anergy or (3) two clinical ARC-criteria (fever, diarrhea, weight loss, fatigue, night sweats). Thirty patients (28 m, 2 f, median age 40 (24-64) years) with ARC (8), WR5 (12) and both (10) were stratified according to T4-cell-count (> versus < 300/µl). Fifteen patients received 0,4g/kg IVIG and 15 patients placebo (albumine 0,03%) every two weeks for 28 weeks. All patients were followed up for another 28 weeks. The clinical status was defined as a score consisting of fever, diarrhea, night sweats, fatigue, weight loss, oral candidiasis, mucosal or cutaneous herpes simplex. Clinical examination and routine laboratory assessments were performed before each application, lymphocyte subsets every four weeks and cutaneous reaction, microbiological serology and tests of phagocytosis and lymphocyte stimulation every 12 weeks.
Results: Results of the treatment period are presented. Both groups were comparable in initial clinical symptoms and laboratory values. Seven patients developed AIDS (3 treatment-, 4 placebo-group), 1 patient died by homicide. In the treatment group the clinical score (particularly fatigue and fever) improved significantly, while T4-cell-count and other clinical and immunological parameters did not show any difference.
Conclusion: IVIG can improve clinical status of patients with ARC and WR5. Further follow-up for 28 weeks may reveal a better insight into the significance of the results reported.

W.B.P.292 CLINICAL EFFICACY OF TWO KINDS OF KAMPO MEDICINE ON HIV INFECTED PATIENTS

Fujimaki,M.1); Hada,M.1); Ikematsu,S.1); Mori,K.2); Takahashi,H.3); Inagaki,M.4); Matsuda,J.5); Mimaya,J.6); Sakuragawa,N.7); Yoshioka,A.8); Fukui,H.8); Kakishita,E.9); Shirahata,S.10); Hattori,T.11); Takatsuki,K.11) and Maruyama,I.12).
1)Tokyo Medical College, Tokyo, 2)Tohoku Univ., Miyagi, 3)Niigata Univ., Niigata, 4)Keio Univ., Tokyo, 5)Teiko Univ., Tokyo, 6)Shizuoka Children's Medical Center, Shizuoka, 7)Toyama Medical and Pharmaceutical Univ., Toyama, 8)Nara Medical Univ., Nara, 9)Hyogo College of Medicine, Hyogo, 10)Univ., of Occupational and Environmental Health, Fukuoka, 11)Kumamoto Univ., Kumamoto, 12)Kagoshima Univ., Kagoshima, Japan

Objective. Two kinds of Kampo Medicine (Sho-saiko-to : SST : Ninjin-to : NT) were administered to HIV infected patients in attempt to improve their immunoabnormalities.
Methods. SST or NT were administered to 56 patients whoes CD4/CD8 ratio pointed below 1.0. And lymphocyte proliferation reaction, single and dual color analysis of lymphocyte were obsereved for 24 weeks.
Results. Clinical data were statistically analyzed for 18 cases which were completed for 24 weeks observation. Immunological improvements were observed in SST treated 7/13 patients and NT treated 9/10 patients from scored analysis used CD4, HLADR$^+$ CD8$^+$ cells and PHA.
Conclusion. The results of this expanded study strongly suggest that especially NT might be a mixture of immunomodifing components.

W.B.P.293 THE EFFECT OF THE POLYENE MACROLIDE ANTIBIOTIC AMPHOTERICIN B AND ITS METHYLATED DERIVATIVE (AME) ON HUMAN IMMUNODEFICIENCY VIRUS AND PHAGOCYTOSIS IN MACROPHAGE CULTURES

Coye, Molly*; Pontani, D.*; Sun, D.**; Wolf, B.*; Bryant, P.*; Shahied, S.*; Brown, J.***; Et Al.
*New Jersey State Department of Health, Trenton, New Jersey; **Laboratory of Tumor Cell Biology, National Institutes of Health, Bethesda, Maryland; ***Roche Biomedical Laboratory, Nutley, New Jersey. U.S.A.

The polyene antibiotic amphotericin B and its methylated derivative AME were tested in continuous macrophage cell lines for activity against HIV-1. At non-cytotoxic levels the expression of HIV-1 was inhibited as shown by the measurement of antigen with both a fluorescent and enzyme marker. At 10 ug/ml there was complete inhibition of virus activity.

To examine the effect of these drugs on the enhancement of monocyte activity, phagocytosis was measured using primary murine adherent cells. Either Sheep red blood cells, naked or coated with antibody, or Listeria monocytogenes were added to the cultures which had been incubated in the presence of each drug at concentrations of 0.1, 1, and 10 ug/ml. Tuftsin was added as a positive control. With both systems there was a significant increase in phagocytic activity in the presence of the polyenes.

These compounds may provide an alternative to AIDS therapies due to their multifunctional cellular activities.

W.B.P.294 Activation of Methionine-Enkephalin (MEK): Enhancement of Cytotoxic T cells in HIV + patients .

N.P. Plotnikoff[1], G.C. Miller[2] and J. Wybran[3].
[1]University of Illinois at Chicago, IL., [2]Immuno-Diagnostics Laboratory, Tulsa, OK, [3]Hospital Erasme, Universite Libre de Bruxelles, Brussels, Belgium.

Asymptomatic HIV + patients were administered infusions of methionine enkepahlin (MEK) at a dose of 60 µ/kg once a week for four months. Numbers of cytotoxic T cells CD3, CD8, CD16 and Leu19 were increased. No side effects were observed. ARC patients receiving MEK, 25-100 µ/kg, 1 to 3x a week also showed increases in numbers of cytotoxic T cells with accompanying reductions in constitutional symptoms (fever, night sweats, lymphadenopathy, weight loss, and diarrhea). Zurawski et al. reported that MEK is a lymphokine that is derived from T helper cells. We are proposing that MEK is a "second messenger" in the expression of receptor numbers and levels of interleukin 2. The resultant increases of NK-K cell activity has been reported to facilitate the inactivation of HIV. MEK may be considered to be an "antiviral immunomodulator".

W.B.P.295 THERAPEUTIC EFFECT OF INTRAVENOUS IMMUNOGLOBULINES (IVIG) IN HIV INFECTED HEMOPHILIAC CHILDREN AND ADOLESCENTS

Wagner, Norbert; Bialek, R.; Radinger, H.; Becker, M.
Dept. of Pediatrics, University of Bonn (FRG)

Objective. To evaluate the effect of long-term application of IVIG in early stages of HIV infection of hemophiliac children and adolescents.
Methods. 36 HIV infected, hemophiliac patients aged 5-20 years (median:15 years) were enrolled in this study. Inclusion criteria were LAS,ARC or a decreased ratio of T helper cells to lymphocytes (<0,35). No patient had AIDS. A group consisting of 18 patients received IVIG, 18 patients served as controls. Stage of HIV infection and age were comparable in both groups, matched pairs were used for analysis.
In the beginning the first group received 0,4g/kg IVIG (Venimmun)on five consecutive days, followed by 0,3 g/kg IVIG given at 14 days intervals. Every 3 months clinical, routine and immunological data, such as incidence of infections, lymphocyte subpopulations, skin reactivity to antigens and lymphocyte response to mitogens and antigens were recorded.
Results.From June 88 until November 88 patients entered this study. At the entry the staging of HIV infection according to the CDC classifications was as follows:

<13 years	>13 years	
P1B 4 patients	IIA 8 patients	III B 4 patients
P2A 7 patients	IIIA 12 patients	IV A 1 patient

Preliminary results 6 months after recruiting the last patient will be presented, including stage progress of the HIV infection, rates of infections as well as development of lymphocyte subpopulations, skin reactivity and lymphoyte stimulation test.

(Supported by the Bundesministerium für Arbeit und Soziales)

W.B.P.296 LONG-TERM ADMINISTRATION OF DITIOCARB IN HIV-SEROPOSITIVE SUBJECTS.

Lang, Jean-Marie; Kirstetter, M.; Livrozet, J.M. and Touraine, J.L.
For the AIDS-Imuthiol French Study Group. Strasbourg, Paris, Lyon. France

Objective. To assess the effects of prolonged administration of ditiocarb (Imuthiol) in HIV-seropositive subjects after double-blind, placebo-controlled short-term trial has shown both clinical and immunological benefit.
Methods. 43 consecutive HIV-infected male homosexuals entered the present open-label study on the basis of CD4+ cell counts ≤ 400/microL and absence of AIDS symptoms as defined by the CDC. Mean CD4+ cell number at entry was 298/microL (± 87). 8 out of 43 subjects had constitutional symptoms at entry. Ditiocarb was given at the dose of 10 mg/kg orally once a week for 4 to 60 months with a median follow up of 22 months. Clinical and immunological evaluation was carried out at 4 month intervals.
Results. During the follow up period 7 patients progressed to AIDS (3 with Kaposi sarcoma and 4 with opportunistic infection) including 3 with initial IVA symptoms. 5/8 with initial constitutional symptoms clinically improved, including 2 with the longest follow up (54 and 60 months). The mean CD4+ cell count at last visit was 310/microL (± 168).
Conclusion. Since about 50 % of asymptomatic male homosexuals with CD4+ cell counts less than 400/microL progress to AIDS in 3 years, the present study cohort given ditiocarb compares favorably with historical untreated cohort. Our data futher suggest that ditiocarb may delay progression to AIDS and demonstrate that the drug can be given safely in HIV infection for a prolonged period of time.

W.B.P.297 SIDE EFFECTS OF IMUTHIOL® (DITHIOCARB, DTC, DIETHYLDITHIOCARBAMATE) IN THE THERAPY OF EARLY STAGE HIV-1 INFECTION.

K. Reisinger*, A. Gottesleben+, G. Götze+, S. Schwander*, A. Dörlemann*, A. Plettenberg§, W. Meigel§, P. Kern*, M. Dietrich*
* Clin. Dptm. Bernhard-Nocht-Inst. for Tropical Med., Hamburg, FRG
+ Dptm. of. Neurol. AK Ochsenzoll, Hamburg, FRG
§ Dptm. of. Dermatol. AK St. Georg, Hamburg, FRG

Objective. We report on the side effects of DTC seen during a prospective randomized placebo-controlled double blind study in 54 HIV-positive male patients. Methods. 13 pat. were treated orally with DTC, 14 pat. orally with placebo (10mg/kgBW once per week) and 13 pat. were treated i.v. with DTC and 14 pat. i.v. with placebo (5mg/kgBW once per week) for 24 weeks. Side effects were reported weekly, clinical, neurological and dermatological examinations were performed in 6 weeks intervals. Results. In oral as well as in i.v. DTC groups, 77% of the patients reported on metallic taste in the mouth for some hours after i.v. medication and for as long as one day after oral medication. Nausea, gastric complaints, flatulence, diarrhea and fatigue were seen with a lesser frequency in both DTC groups. A superficial gastritis was diagnosed in one patient after 24 weeks of oral DTC administration. Due to the antabus-activity of DTC, intolerance to alcohol (palpitation of the heart, skin rush, dizziness, nausea, headache) was realized. In the placebo group, imaginary side effects were seen in a low frequency and irregularly. No allergic-toxic reactions nor neurologic or haematopoetic side effects could be found.

W.B.P.298 CLINICAL EVALUATION OF GLYCYRRHIZIN ON HIV-INFECTED ASYMPTOMATIC HEMOPHILIAC PATIENTS IN JAPAN

Ikegami, Nobuko; Yoshioka, K. and Akatani, K. Osaka National hospital, Osaka, 540, Japan.

Objective. To evaluate the clinical effectiveness of glycyrrhizin (GL) by long -term oral administration on HIV-infected asymptomatic patients.
Methods. Glycyrrhizin is one of the biologically active components present in extract of glycyrrhiza glabra roots. The chemical structures of GL and its aglycone component, glycyrrhetinic acid (GA) are known. Both GL and GA have the ability to induce interferon in mice received the drugs orally (a report by Abe et al.), and GL has the antiviral activity on HIV infection in cell culture system (a report by Ito et al.) In this clinical trial, HIV-infected asymptomatic patients were divided into two groups, untreated and treated with GL. The patients in the latter group have received daily oral dose of 150 to 225mg of GL for 12 to 24 months. Lymphocyte and lymphocyte subsets counts of peripheral bloods of the patients were carried out at least twice a year, and immunologic abnormalities were compared among the patients by the scale scores, as described by Zolla-Pazner et al. (PNAS, 84: 5404, 1987).
Results. It has been found that the long-term oral administration of GL to the ten asymptomatic HIV-infected patients whose immunologic abnormalities are the score 1 or 2, is effective to maintain their asymptomatic stages. Neither progression of immunologic abnormalities nor development of diseases has not been seen upto now. Of the ten untreated patients, two have developed AIDS (score 3) and died. One has developed lymphadenopathy (score 3).
Conclusion. The treatment with GL appears to be effective to the patients in preventing disease development from their asymptomatic stages.

W.B.P.299 INTRAVENOUS VERSUS ORAL APPLICATION OF PENTOSAN-POLYSULFATE (HOE/BAY 946) IN HIV INFECTED PATIENTS.

Peters, Malte; Ruf, B. and Pohle, H.-D.
II. Department of Internal Medicine, Rudolf Virchow University Hospital (Wedding), Freie Universität Berlin, FRG.

Pentosan-polysulfate has been shown to have HIV-1 inhibitory properties in vitro and perhaps in vivo. It is poorly absorbed through the gastrointestinal tract. Therefore, with oral application, effective intracellular concentrations will be achieved only after a long period. This implicates high oral dosages. We performed a prospective clinical study in HIV infected patients with an initial two week period of intravenous (IV) application of pentosan-polysulfates before oral maintenance therapy. The aim of the study was to compare clinical status and immunological parameters of orally treated patients and of patients with initial IV application of the drug.

We compared patients who had initial IV treatment (1 x 100-300 mg/d) with patients who were only treated orally (3 x 150-450 mg/d). Patients were in stages LAS or ARC. Changes of blood coagulation parameters after onset of therapy and transiently impaired liver function have been noted in IV treated subjects. Patients who had oral application only did not show any side effects. Differences concerning the data of clinical examinations, immunological data, and some serum kinetics will be presented.

Initial IV application of pentosan-polysulfate with a subsequent oral maintenance therapy may be recommended, because of a probable initial cellular loading effect. However, more detailed clinical data are needed. Since almost every patient with IV treatment developed side effects, IV therapy should be performed only in careful clinical trials in hospitalized patients.

W.B.P.300 TWO YEAR CLINICAL TRIAL WITH PENTOSAN-POLYSULFATE (HOE/BAY 946) IN HIV INFECTED PATIENTS.

Ruf, Bernhard*; Peters, M.*; Schürmann, D.*; Rübsamen-Waigmann, H.** and Pohle, H.-D*.
*II. Department of Internal Medicine, Rudolf Virchow University Hospital (Wedding) Freie Universität Berlin; **Chemotherapeutisches Forschungsinstitut, Frankfurt, FRG

Pentosan-polysulfate has been shown to be effective against HIV-1 in vitro. We performed an open clinical pilot study with pentosan-polysulfate (HOE/BAY 946) in HIV infected patients in order to find an appropriate dosage, investigate antiviral properties, reveal possible side effects, and to determine whether subsequent clinical studies are needed.

We examined a total of 40 patients over a period of two years. 15 patients were stage LAS, 10 stage ARC, and 15 patients were in the stage of AIDS (CDC classification). Pentosan-polysulfate was given orally three times a day with an increasing dosage from 150 mg to 450 mg. Full clinical status was obtained on every clinical examination; additionally routine laboratory data and immunological examinations (lymphocyte counts and subsets, neopterin, β_2-microglobulin) were performed.

None of the patients changed the stage of HIV infection. Three patients in stage ARC, and 12 AIDS patients developed opportunistic infections. Eight of the 15 AIDS patients died. Immunological parameters showed increasing lymphocyte counts and lymphocyte subsets in LAS patients, stable cell counts in ARC and decreasing cell counts in AIDS. None of the patients developed side effects caused by pentosan-polysulfate.

Pentosan -polysulfate could be an effective agent against HIV in early stage disease, whereas in AIDS beneficial effects have been seen only rarely. ARC patients remained stable. Our data justify longer examination periods and randomized placebo-controlled trials.

W.B.P.301 Clinical influence of Imuthiol^{R} (sodium ditiocarb) in HIV-infected patients.

A review of 4 controlled studies and long term influence.

Caraux, Jean The International AIDS Imuthiol study group (France, Germany, USA.) Lyon France.

Between November 1983 and December 1988, more than 2,100 HIV-infected patients have been enrolled in double-blind, placebo controlled studies of Imuthiol^{R} (sodium ditiocarb, DTC). To date, results from three controlled studies in 170 ARC patients are available and results from a study in 267 ARC patients and 105 AIDS patients in 8 US medical centers will be available before June 1989. In France, 1,600 asymptomatic/LAS patients have been enrolled in a long term double-blind, placebo controlled study between July 1987 and July 1988. This study is ongoing.

From the first three controlled studies (US, France, Germany), three clinical end points have reached statistical significance :

1. Imuthiol delayed progression to AIDS in ARC patients : 15 patients progressed to AIDS in the controlled group vs 2 in the Imuthiol groups. This was statistically significant in the German study (6 progression vs none, $p < 0.05$, Logrank test).
2. Imuthiol slowed down progression in CDC class in ARC patients
3. Imuthiol induced regression in some constitutional symptoms of HIV-infection (group IV-A symptoms, lymphadenopathy, splenomegaly).

The US multicenter study on 372 patients is now terminating and results on major clinical efficacy endpoints will be available in June.

W.B.P.302 TWO MONTH DOUBLE BLIND PLACEBO CONTROLLED TRIAL OF CYCLOSPORIN IN HIV ASYMPTOMATIC SUBJECTS

J.P. Aboulker, J.M. Andrieu, J.A. Gastaut, P. Debré, B. Milpied-Homsi et al. Groupe INSERM CICLO-T4. FRANCE

OBJECTIVE : To evaluate, in a multicenter, double blind, placebo controlled trial, the short term effects of cyclosporin on peripheral CD4 counts.

METHODS : 98 HIV asymptomatic or lymphadenopathic seropositive patients with initial CD4 counts between 300 and 600/mm3 were randomly assigned to cyclosporin 7.5 mg/kg per day or placebo for a 9 week period of treatment. Doses were adapted in order to maintain trough whole blood levels ranging from 400 to 700 ng/ml. Cyclosporin dose was in average more than 6.9 ng/ml throughout the trial. The double blind design was preserved by adapation of placebo doses of matched controls.

RESULTS : A significant ($p<0.001$) CD4 cell increase was observed in cyclosporin group compared to placebo at week 1 (+107/mm^3) and week 2 (+98/mm^3). Similar increase was observed in CD8 cell and total lymphocyte counts, thus the proportions of CD4 and CD8 subsets and the CD4/CD8 ratio did not change. At week 9 CD4 cell counts were in average identical in the 2 groups. Side effects observed were mild and no adverse reaction or progression to AIDS or ARC occured during the 4 month period (treatment and follow-up) of the trial.

CONCLUSION : The effect of cyclosporin on circulating CD4 + lymphocytes was limited to a transient and weak increase, but it is not possible to come to a conclusion regarding the efficacy of a long term immunosuppressor treatment on the basis of the results of this 2 month trial.

W.B.P.303 ACUTE RESPONSES TO AMPLIGEN INFUSIONS IN HIV-INFECTED PEOPLE

Pazin George J, Huang XL, McMahon D, Armstrong JA, Rinaldo C, Ho M and Pittsburgh AIDS Clinical Trial Unit investigators, University of Pittsburgh, Pittsburgh, Pennsylvania, U.S.A.

OBJECTIVE: To report our clinical and laboratory observations in HIV-infected persons associated with acute reactions during intravenous infusions of synthetic mismatched double-stranded RNA (Ampligen).

METHODS: Ten acute reactions (flushing, diaphoresis, shivering, chills, fever and chest tightness) occurred in 3 of 17 persons receiving twice weekly infusions. Infusions were stopped temporarily during reactions then finished at a slower rate. No reactions required discontinuation of treatment.

RESULTS: Reactions were observed in 0/6 persons receiving 10 mg/M^2, 1/6 receiving 40 mg/M^2 (person #200g) and 2/5 receiving 120 mg/M^2 (persons #217c and #229j). Acute depressions of PMNs were observed as soon as reactions subsided (within 15 minutes) and at end of reinfusions and were followed by leukocytosis. Leukocyte counts ($x10^3/\mu l$) are summarized as follows:

Patient	Pre-infusion	End-reaction	End-infusion	1-2 hrs. later
#200g (3 obs.)	5.6	-	2.9	8.8
#217c (3 obs.)	6.7	3.1	7.5	9.3
#229j	3.3	2.1	3.2	4.3

Granulocytes were mainly responsible for these changes. During 6/7 reactions cytotoxic activity of peripheral leukocytes against K562, U937 and HIV-infected U937 targets were depressed 2 hr post-reactions as compared to pre-infusion values. CONCLUSIONS: Acute leukopenia associated with Ampligen-infusion-reactions was followed by leukocytosis 1-2 hrs. later. Cytotoxicity against three different targets was also suppressed at 2 hours.

W.B.P.304 Failure of isoprinosine in prevention of ARC to AIDS

Barbaro, Daniel and Fragua, H. University of Texas Southwestern Medical Center at Dallas, Texas, U.S.A.

Objective. To determine the effect of an immunomodulator, Isoprinosine(Inosine pranobex) in delaying the progression of disease in HIV seropositive male patients with CD4 counts of 200-400/mm^3.

Methods. A prospective, multicenter, randomized, double blinded, placebo controlled clinical trial. 202 seropositive homosexual males were screened in Dallas County and 50 patients were entered into the study.

Results. 21 patients completed 12 months of the trial. 19 patients were discontinued; of these 8 discontinued themselves to go on AZT, and 11 were lost to followup. 9 patients endpointed with AIDS. 1 patient developed interstitial nephritis-one of the four reported adverse reactions.

Conclusions. Isoprinosine was ineffective in preventing the progression of ARC to AIDS. Overall, there was no toxicity noted but the drug failed to prevent the destruction of CD4 lymphocytes, development of HIV antigenemia and clinical deterioration. Further studies combining this agent with other antivirals need to be performed.

W.B.P.305 Neopterin and T-helper/neopterin ratio in the monitoring of long-term treatment of HIV-infected patients by Imuthiol^{R} (sodium ditocarb, DTC)

Myriam Kirstetter*, André Burkel*, Anne Felten***
*Hôpital St-Antoine (Service Prof. Frottier), **Laboratoire Burkel, ***Institut Merieux, Paris and Lyon, France.

Objective. To investigate whether urinary neopterin (UN) and T-helper (T4) / UN ratio correlates with prognosis in long-term therapy by Imuthiol^{R}.

Methods. 36 HIV-infected male homosexuals (age 37, range 22-45 years, weight 71 kg, range 57-84) were treated with Imuthiol^{R} (10 mg/kg once a week) for a mean duration of 17 months (range 6-30 months), starting in August 1986. 21 belonged to group III and 15 to groups IV-A and IV-C2 at entry. 27 had less than 400 T4 cells at entry. Patients were monitored every 3 months. UN (μ mol/l) was assayed by HPLC and T4 cell counts by cytofluorometry.

Results. Among over 100 evaluations, the T4/UN ratios correlated well with absolute T4 levels. In 3 instances, an elevation of UN was seen without decrease of T4 counts. This was related to associate viral infections. Under Imuthiol therapy, T4/UN ratios increased in 10/36 patients, was stabilized in 20/36 patients and dropped in 6/36 patients. Only one of those 6 progressed to an Aids-OI.

Conclusion. T4/UN ratio is useful in monitoring progression of HIV-infected patient. It remains stable or increases in 30/36 patients treated with Imuthiol for prolonged periods of time.

W.B.P.306 TIMOMODULINE AND LITHIUM CARBONATE FOR HIV PATIENTS

BUCHOVSKY G,POPESCU B,LEVIN C,CORRALES J,SANZ M,ESBIVEL G,
HOSPITAL Gral.san Martin ; Corrientes, ARGENTINA.

OBJECTS: It is well known the trophism of HIV, which affects the lymphocytes T4 and Monocytes; leading to immunosuppresion. A study was undertaken using Timomoduline, a stimulator of lymphocytic maturation and a Granulocytic-Monocytic colony forming unit activator(GMF-CSF) and Interleukina II in vitro, Lithium Carbonate.

METHODS: (7) seven patients infected with HIV,(2) two with demential complex,(I) one with ARC,(I) one with AIDS and (3) three with LAS were (5 homosexuals, 2 sevral blood transfusions; they were all males with an age average of 37 years). They had a positive serology for HIV and immunosuppresion was showed up, caused by a fall of CD4 under 400 cel./ mm3. They were treated with Timomoduline 60 mg/day/orally and LITHIUM Carbonate 900mg./day during a I6 week period.

RESULTS: during the study period (2) two of the seven patients died because of demential complex. The remaining ended the treatment protocol. All of the patients experienced physical improving. Four of them gained weight. None of the patients experienced any kind of side-effects. There was an increased in the lymphocyte total level, monocyte and CD4.

CONCLUSIONS: After this study period we can conclude that; the anti-HIV treatment is necessary for patients who experienced a demential complex. The remaining ones manifested a clinical improving. We conclude that Timomoduline and Lithium Carbonate should be used for Pre-AIDS,and Anti-HIV association for patients on advanced AIDS stages.

W.B.P.307 CASE REPORT OF DISULFIRAM AS FIRST LINE THERAPY IN SEROPOSITIVE PATIENTS ATTENDING A COMMUNITY CLINIC

Davis, Iris; Leibel J; Paroski P; Morgan A; Norris B; et al. Woodhull Medical and Mental Health Center, Brooklyn, NY, USA

Objective: To use disulfiram in treatment for HIV seropositive asymptomatic patients and explore if there is a significant correlative change between T4/T8 ratio and/or absolute T4 count. Method: Seropositive patients with T4/T8 ratios less than 1.20 or absolute T4 counts <500 were started on disulfiram - a split weekly dosage of 1000 mg. T4/T8 counts and ratios were followed every three months for a period of six months. Pre-treatment and post-treatment differences were evaluated by the student T test. Results: In a sample of 10 patients on disulfiram alone, a comparison of initial and nine month followup in the ratio of T4/T8 cells, absolute T4 and absolute T8 counts reveals a statistically significant improvement at the .05 level with a one sided T test. Of these 10 patients, 8 had documented improvement in T4/T8 ratio. Assuming a population probability of .5 the power to detect a difference is less than 50%. Graph and data will be presented. Conclusion: Although the sample size is small, a statistically significant difference was noted in seropositive patients on disulfiram treatment. These results suggest a large scale study of disulfiram should be initiated to further delineate the treatment effect.

W.B.P.308 IMMUNOLOGIC AND VIROLOGIC PARAMETERS IN 100 HIV-INFECTED PATIENTS (PTS) TREATED WITH ISOPRINOSINE (ISO) OR PLACEBO (PLB) AS PART OF A MULTICENTER PHASE III CLINICAL TRIAL

Stein, Marcelo; Schalof, R.; Mai, D.; Simon, G.; Parenti, D.; Courtless, J.; et al.
The George Washington University Medical Center; Washington, DC, USA

Objective: To provide confirmation that ISO (inosine pranobex) exhibits immunorestorative effects, and establish whether it exhibits HIV suppressive effects in a large scale double-blind placebo-controlled clinical trial.

Methods:

Study Design: Randomized double-blind, placebo-controlled multicenter (19 centers in the USA/UK) phase III clinical trial. Subjects: HIV-seropositive males, aged 18-75 years; CDC Groups II, III, IV-A, IV-C2; CD4 counts between 200-400/mm^3.

Treatment: ISO - 4 gm/day po (1 gm QID) or PLB for up to 6 months.

Results: A total of 696 PTS were enrolled, of which 100 were treated at our center. Baseline and post-treatment parameters of 79 PTS who completed 6 months of therapy are shown in the table below.

Treatment Group		Mean CD4/mm^3	Mean MLR (% Control)	Mean Tetanus (% Control)	Mean IL-2 (% Control)	Mean NK (% Control)	# DTHS Anergic	# p2[illegible]
ISO	pre-rxn	333	37	18	69	92	13/32	[illegible]
(n=37)	post-rxn	264	28	11	71	87	8/32	9/37
PLB	pre-rxn	333	49	20	70	93	14/40	18/39
(n=42)	post-rxn	261	37	20	97	84	16/40	19/40

On serial monitoring (Q 2 months), no significant differences were seen on virologic (p24), or in vivo (DTHS) or in vitro immunologic parameters [lymphoproliferative responses to alloantigens (MLR), soluble antigens (tetanus), PHA-induced IL-2 production, or NK activity], in PTS treated with ISO or PLB. Mean CD4 counts, and in vitro immune reactivity tended to decrease gradually with time in both groups. No drops in serum p24 levels were observed.

Conclusions: We could not confirm that ISO exhibits immunorestorative effects in HIV-infected PTS.

W.B.P.309 RECOMBINANT HUMAN GRANULOCYTE-MACROPHAGE COLONY-STIMULATING FACTOR (GM-CSF): A PHASE I TRIAL IN NEUTROPENIC AIDS PATIENTS.

Krown, Susan E., O'Boyle, K., Gold, JWM, Flomenberg, N., Anselmo, W. and Bonnem, E.* Memorial Sloan-Kettering Cancer Center, New York, NY, USA and *Schering Corporation, Kenilworth, NJ, USA.

Objective. To evaluate the safety, efficacy and biological activity of subcutaneously (SC) administered GM-CSF in AIDS patients (pts) who were neutropenic as a result of treatment or their underlying disease. Methods. AIDS pts with ANC<2000/mm^3, PS≥60, Hb≥9, platelets ≥75,000 and SGOT≤50 were eligible. GM-CSF was given by daily SC injection for 10 days. After an 18 day rest, treatment was resumed for 28 days. Pts were then evaluated for maintenance treatment. Results. Twelve pts have been entered at GM-CSF doses of 0.3, 1, 3 and 10 µg/kg/d. The median ANC was 900/mm^3 (range 400-1700). Five pts were receiving AZT and 7 had sustained neutropenia after stopping AZT treatment. Dose-dependent increases in ANC were seen. Mean maximum ANCs were 3467 (0.3 µg), 3833 (1µg) and 6520 (3µg). At each dose there was considerable variation in the ANC response and the degree of eosinophilia. Peak ANCs were generally lower in pts receiving AZT, but in some who had previously discontinued it, AZT could be reinstituted at reduced doses. Fever, malaise, weight loss and increased liver enzymes were observed in some pts. We saw no evidence for stimulation of HIV, as measured by serum p24 antigen or cultures of peripheral blood cells, nor were there consistent effects on T cell subsets or the functions of NK cells, neutrophils or monocytes. Conclusions GM-CSF can reverse established neutropenia in AIDS pts. Given the variable response, optimal treatment may require dose titration.

W.B.P.310 REESTABLISHMENT OF A NORMAL IMMUNOREGULATORY MECHANISM IN HIV-INFECTED PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA (ITP)

Snyder, Harry W., Jr.; Jones, F.R. and the PROSORBA Clinical Trial Group. IMRÉ Corporation, Seattle, WA, USA, 98109.

Objective - To modulate activity of platelet-directed IgG (PDIgG) and circulating immune complexes (CIC) by PROSORBA® column treatment of plasma from patients with ITP. Methods - Ninety-seven patients with chronic ITP (39 patients with HIV-infection) received 4-8 treatments, involving adsorption of 250-2000 ml plasma, with the U.S. FDA approved PROSORBA column over a 4-6 week period. Results - PDIgG and CIC were significantly reduced in both HIV-infected and uninfected ITP patients. In HIV-infected patients this was shown to be in response to stimulation of broadly cross-reactive anti-F(ab')$_2$ antibodies which bound to both PDIgG and CIC and enhanced their clearance from the circulation. In uninfected ITP patients, this was shown to be in response to stimulation of specific anti-idiotypic antibodies which neutralized the activity of idiotypic PDIgG. In both patient populations, these activities were associated with normalization of platelet counts in many patients (47% overall) which are continuing to be sustained over a mean follow-up period of 8 months. Conclusion - PROSORBA column treatment of plasma to remove IgG and CIC induces reestablishment of normal immunoregulatory mechanisms which suppress autoantibodies and prevent development of ITP. This leads to long-term remission from disease.

W.B.P.311 AMELIORATION OF DETERIORATED POLYMORPHONUCLEAR LEUKOCYTE(PMN) PHAGOCYTI FUNCTION OF HEMOPHILIACS WITH HIV INFECTION BY ADMINISTRATION OF LONG-TERM POLYSACCHARIDE IMMUNOPOTENTIATOR (LENTINAN)

Matsuda, Juzo, Gohchi,K., Kinoshita,T. and Abe,T.
Department of Medicine, Teikyo University School of Medicine, Tokyo, Japan.

ObjectivePMN phagocytic function(PMN-PF) of hemophiliacs(H) was evaluated in vitro and the effect of long-term treatment with lentinan on impaired PMN-PF was studied. Method.PMN-PF of 39 H, including 22 cases with HIV infection, was measured as the intensity of PMN chemiluminescence(PMN-CL) evolved from PMN when stimulated with opsonized zymosan(OZ) and/or phorbol myristate acetate(PMA). Ten mg of lentinan was injected(iv) to 7 H(5AC, 1ARC & 1 HIV negative) with an impaired PMN-PF. Results. OZ stimulated PMN-CL of 22 HIV positive as well as 17 HIV negative H was revealed to be deteriorated to 0.68 ±0.31 & 0.74±0.22(normal range;0.8-1.2) respectively. This tendency of deterioration was confirmed with PMA stimulated PMN in both HIV positive(0.74± 0.31) and negative(0.96±0.24) groups. PMN-CL in 6 out of 7 H on long-term lentinan treatment was recovered to the near normal range within less than 3 months and this normalized PMN-CL was maintained for 6 to 28 months after cessation of the medication. Moderate to marked increment in CD4/CD8 ratio was observed in 3 cases. Conclusion. Long-term treatment with lentinan offers a therapeutic potential for HIV infected individuals with impaired PMN-PF by by which PMN dysfunction is corrected and the onset of oppotunistic infection is prevented. On the basis of these results, open trial of lentinan for HIV infected patients has just started in 16 medical universities and hospitals throughout Japan.

W.B.P.312 AN OPEN LABEL DOSE-RANGING TRIAL OF AL721 IN PGL AND ARC.

Mildvan, D.[1]; Armstrong, D.[2]; Antoniskis, D.[3]; Sacks, H.[4]; Balfour, H.[5]; Buzas, J.[6]; Pettinelli, C.[7]; et. al.
[1]Beth Israel Med. Cent., NY; [2]Memorial Sloan-Kettering Cancer Cent., NY;U.S.A. [3]U. of S.Cal., LA; [4]Mt. Sinai Med. Cent., NY; [5]U. of Minn.; [6]Res. Triangle Inst., NC; [7]AIDS Clin. Trials Group, NIAID. Objective: To assess the safety and tolerance of escalating doses of AL721, a lipid compound with reported anti-HIV activity via cell membrane or virion cholesterol depletion. Methods: The study was a multi-center open label dose-ranging trial in patients with PGL and ARC. AL721 was administered for 8 weeks at 20, 30, 40, or 50 grams twice daily to 10 patients at each dosage level. Patients were evaluated for toxicity and disease progression. Immunologic (T-cell subsets), virologic (HIV cultures, p24 antigen levels), and serum lipid profiles were also monitored. Results: 40 patients were treated. Toxicities were confined to the GI tract: 60% of patients across doses experienced mild, and 10%, moderate diarrhea. Mild to moderate nausea and abdominal pain occurred in 40-50%. Reactions were usually self-limited, and none led to termination of therapy. Disease progression was not noted in this short-term study. No consistent trends were observed in T-cell quantitation or HIV cultures. 3 patients were p24 antigenemic (≥70pcg/ml) at entry; all remained so on treatment. Statistically significant increases over baseline were noted in weight (2%), total cholesterol (13%), HDL (10%), and LDL levels (14%). Conclusions: AL721 was well-tolerated, even at high doses, over 8 weeks, and resulted in modest wt. gain. One consequence of therapy, however, was a significant increase in serum cholesterol levels. No preliminary indication of an antiviral or immunorestorative effect was noted in this trial. Additional p24+ patients are being treated to assess antiviral endpoints.

W.B.P.313 INOSINE PRANOBEX THERAPY IN HIV SEROPOSITIVE PATIENTS AT RISK OF DEVELOPING AIDS.

Murphy Robert; Von Roenn J; Pottage, J; Williams L; Benson, C; Kessler, H; and Phair J. Northwestern University Medical School and Rush Medical College, Chicago, IL. U.S.A.

Inosine Pranobex(ISO), a synthetic immunopotentiating agent, was administered orally in a prospective, placebo-controlled, randomised, double-blind trial to 122 HIV seropositive, non-AIDS, male patients(pts) with an absolute CD4 count between 200-400 cells/mm^3 at entry. Objectives were to determine whether ISO can delay progression of disease and/or decrease severity and incidence of lessor opportunistic infections and conditions associated with HIV. Study pts received ISO 1.0g PO QID or placebo(c) for 6 months(mo). After 6 mo, all pts were offered ISO for an additional 6 mo.

CD4 count (cells/mm^3)

Results:	Baseline	6 mo.	Δ0-6 mo.	12 mo.	Δ 6-12 mo.	Δ 0-12 mo.
ISO Pts:	322.8	287.6	-35.2	248.1	-51.6	-73.4
C Pts:	322.8	291.3	-31.5	261.8	-43.7	-64.9

3 ISO and 3 C pts developed AIDS during the study. There were 4 adverse reactions in each group. 8 ISO and 11 C pts were antigen(AG)⊕ at baseline. By the end of the study, 4/7 Ag⊕ ISO pts converted to ⊖ and 3/47 Ag ⊖ pts became ⊕ 3/11 Ag⊕ C pts converted to ⊖ and 3/47 Ag ⊖ pts became ⊕.
Conclusions: There were no statistically significant differences between the groups at baseline, 6 months or 12 months in regard to CD4, P24 antigen or clinical status. ISO was ineffective in altering the immunologic and clinical findings associated with HIV infection in this moderately immunosuppressed seropositive group of patients at risk for developing AIDS. Other study sites have reported similar findings.

W.B.P.314 EFFECT OF PASSIVE IMMUNIZATION IN PATIENTS WITH ARC AND AIDS

Karpas, Abraham*; Hill, F*; Youle, M**; Gray, J*; Oates, JK**; and Gazzard, B**.
*Dept. of Haematology, University of Cambridge Clinical School, UK.
**St. stephen's Hospital, London, UK.

Objective: To determine the benefits of passive immunization in ARC and AIDS.
Methods: Plasma was collected from healthy HIV positive donors who had high titres of antiviral antibodies as monitored in the Karpas cell test. β-propiolactone was used to inactivate viruses. ARC and AIDS patients received monthly transfusions of 500 ml pooled plasma. Level of HIVp24 antigen, antibody titre, T-4 cell counts, weight as well as other parameters were measured at monthly intervals.
Results: Plasma transfusion to the 10 consistently viral-antigen-positive patients (mean 76 months) resulted in sustained clearance of HIV|p24 antigen. All patients maintained or increased their antiviral antibody titres. Two ARC patients had a significant increase in endogenous antibody synthesis. Only in the ARC patient with the rapid increase in antibody levels was there a noticeable increase in T4+ cells. Four of the remaining 8 patients (one went abroad and one died) did not require hospitalization during the past 10 months. No toxicity was observed in patients receiving plasma from donors of the same ABO group.
Conclusion: The above beneficial observations combined with no obvious toxicity merits further evaluation in ARC and AIDS patients. The significant increase in antiviral antibody level (synthesis) in two ARC patients suggests that an early institution of passive immunization might prevent the deterioration to ARC and AIDS.

W.B.P.315 A PHASE I/II DOSE RANGING TRIAL OF ORAL DEXTRAN SULFATE IN HIV p24 ANTIGEN POSITIVE INDIVIDUALS (ACTG 060): RESULTS OF A SAFETY AND EFFICACY TRIAL

Abrams, Donald; Pettinelli, C; Power, M; Kubacki, VB; Grieco, MH; Henry, WK; and the NIAID ACTG 060 Protocol Co-Investigators; NIAID AIDS Program, Bethesda, Maryland, USA.

Objective. To evaluate the long-term toxicity, establish the maximally tolerated dose (MTD) and evaluate the antiretroviral activity of oral dextran sulfate (DS) (MW 7,000-8,000, 17-20% sulfur, Uendex) in HIV p24 antigen positive patients.
Methods. A multi-center unblinded 6 month trial of at least 2 doses of DS was designed. HIV p24 antigen positive patients were enrolled and stratified into 3 different cohorts: AIDS, ARC and asymptomatic. Ten patients were enrolled in each of these cohorts at 2700 mg/day. At least 5 of the asymptomatic and 5 of the ARC patients retained CD4 lymphocyte counts of greater than 200/mm^3. The next 30 patients were begun on DS at 5400 mg/d. Patients were monitored with physical examinations and laboratory testing every other week for 3 months, then monthly for 3 months. Toxicities were graded using the standard Recommendations for Grading of Acute and Subacute Toxic Effects. An MTD was defined as the highest dose for which less than 5 of the 10 patients in a cohort developed toxicity of Grade 3 or above. Dose escalation beyond 5400 mg was planned if the MTD had not been reached by that dose level.
Results. To date 60 pts have been accrued since the study began in August 1988. The mean and median duration of therapy is 12 weeks. Nine patients have developed Grade 3 episodes of diarrhea; however a significant additional number also report intolerable bloating and crampy abdominal pain. Five patients report polyuria; 4 developed skin rashes and pruritus; 3 mental status changes. The most common laboratory toxicities reported include elevated hepatic transaminases (9 patients); granulocytopenia (5 patients); and Grade 3 thrombocytopenia (2 patients). Twenty-two patients are currently off study drug; 5 because of toxicities; 9 voluntary dropouts; 4 others and 4 because of physician advice after preliminary data from a pharmacokinetic study suggested poor bioavailability of oral DS. Immunologic and virologic parameters are currently being analysed.
Conclusion. Oral DS is not without toxicity despite the current lack of conclusive evidence of systemic absorption. Lymphocyte subsets and HIV p24 antigen are being evaluated.

W.B.P.316 *EFFET DU MM1 SUR LES MALADES ATTEINTS DU SIDA*

Z. LURHUMA, A. SHAFIK, N. DIESE, J.NANE, K.TSHIAMALA & B. BINAMISANA, Kinshasa, ZAIRE

Nous avons suivi 464 patients atteints de SIDA du 13 mai 1987 au 20 mai 1988. Ces patients sont soit ambulants soit hospitalisés aux CUA ou à la Clinique Ngaliema. Parmi eux, il y a 196 hommes dont l'âge est entre 19 et 56 ans et la moyenne d'âge est de 38.5 ans; et 268 femmes dont l'âge est situé entre 15 et 50 ans avec une moyenne d'âge de 29 ans.

Les manifestations cliniques sont dominées par l'amaigrissement (88.5%), l'asthénie (99.9%), la diarrhée (63.7%), le prurit (40%), la candidose digestive (60.9%), le prurigo (40%), les pneumopathies (70%), le sarcome de Kaposi (20.1%), le zona (20.4%), l'herpès cutanéo-muqueux (20%), la fièvre (68.7%), la furonculose (10.3%), la méningite à cryptocoque (7.1%).

Après 20 injections de MM1 administré soit par IM soit par IV (perfusion) et un traitement classique des infections opportunistes, nous avons noté l'évolution suivante: un gain pondéral dans 90.4% de patients; une disparition de l'asthénie dans 97.1% de cas; un amendement de la diarrhée dans 62.9%, du prurit dans 83.4%, du prurigo dans 52.9%, de la fièvre dans 97%: une réduction de l'adénomégalie dans 90.7% et une guérison de la méningite à cryptocoque dans 40.2%. Au contraire, le sarcome de Kaposi ne semble pas être influencé par le MM1. Nous avons aussi remarqué l'amélioration des paramètres biologiques suivants: le nombre total des lymphocytes "helper" dans 80% des cas; tandis que l'hémogramme, les fonctions rénales et hépatiques aussi bien que les protéines sériques ne sont pas perturbées. Dans le cas des patients dont le taux des transaminases était augmenté, nous avons remarqué une diminution.

Thérapie et évaluation clinique : tests contrôlés
Therapy and Clinical Evaluation: Controlled Trials

W.B.P.317 USE OF ZIDOVUDINE IN INJECTION DRUG USE (IDU) RELATED HIV INFECTION - DRUG COMPLIANCE AND CLINIC ATTENDANCE.

Cowan FM, Jones ME, Flegg PJ, MacCallum LR, Brettle RP, Gray JA, et al. Infectious Diseases Unit, City Hospital, Edinburgh.
UNITED KINGDOM

Objective: The evaluation of drug compliance and clinic attendance in zidovudine treatment of injection drug use related HIV infection (IDUHIV).
Method: 322 HIV seropositives were assessed at the City Hospital, of which 253 (79%) were infected between 1983-85 by IDU. Of 51 treated with zidovudine, 37 were male (22 IDUHIV, 15 homosexuals [HO]) and 14 were female (13 IDUHIV, 1 heterosexual partner of IDUHIV). Drug use included opiates, benzodiazepines and cannibis. Compliance was assessed by attendance records, weight (wt) and mean corpuscular volume (mcv).
Results: 27 (75%) of 36 were on oral opiates (19 methadone, 8 other opiates) 8 were ex IDUHIV, (but 5 continued with cannibis/benzodiazepines). Six patients continue to inject.

Group No. ( )		Homos. (15)	Ex/non-users(8)	Oral Opiates (27)	Inject/Oral Opiates (6)
No of Defaults:	0	14	4	15	3
	1-3	1	5	10	3
	>4	0	0	2	0
Mean Wt gain [kg](Range)		0.4(-11to13)	2.7(-2to10)	-0.1(-13to9)	1.0(-5to9)
Mean mcv gain[fl](Range)		19.2(-8to32)	15.5(4to25)	16.6(-1to38)	27.7(20to30)

Conclusions: Rise in mcv and wt were comparable in both groups. IDUHIV were worse attenders than HO patients and the most reliable attenders were those prescribed methadone by ourselves and was unrelated to continued IDU.

W.B.P.318 EFFECTIVENESS OF LOW-DOSE-COMBINATION THERAPY WITH ACIDOTHYMIDINE (ZIDOVUDINE) AND ACYCLOVIR IN AIDS- AND ARC-PATIENTS

Walser, Peter, P. Baumgart, G. Wilke, U. Kupfer, A. Schwaaf, E.G. Dorst et al. Medizinisce Poliklinik, University of Munster FRG.

Objective: Examination of effectiveness of AZT/ACV low-dose therapy in regard to clinical, virological and immunological parameters in AIDS- and ARC-patients.
Methods: Open prospective study of 54 patients (19 AIDS, WR6; 35 ARC, WR 4-5) receiving low-dose-comb. of AZT/ACV (200 mg 4x daily). We evaluated clinical and labor. data (red and white cells, OKT 4, P-24 Ag, immunolog. paramet.) and influence on quality of life due to side effects.
Results: After an average treatment-duration of 36(20) weeks, we evaluated data of 50 patients (mean age 33,4,8,4y). 4 patients died within the first 4 weeks. No serious side effects were observed. Therapy had to be interrupted in 17 cases, in 11 cases because of leukopenia and/or anemia. 10 patients required transfusions, in 7 cases due to AZT/ACV therapy. Mortality was 8% (4/50). Morbidity caused by opp. Inf. was 12% (6/50). We observed 4 of these OI after therapy interruption > 4 weeks. 4 patients suffered from a lymphatic neoplasia, lethal in 2 of them. In 8 of 10 cases initially high P-24 Ag concentrations were suppressed during therapy. Effects on parameters of cellular (OKT 4) and humoral immunity (CIC,B-2M) were transitory.
Conclusion: A low-dose therapy with 800 mg AZT and 800 mg ACV seems to have similar positive effects on reduction of mortality and prevalence and severeness of opp.Inf. as standard AZT monotherapy. Toxicity seems to be reduced. Effects on compliance are positive.

W.B.P.319 ALLOGENEIC BONE MARROW TRANSPLANTATION (BMT) PLUS AZIDOTHYMIDINE (AZT) IN AN AIDS PATIENT WITH NON-HODGKIN'S LYMPHOMA (NHL)

Holland HK*, Rossi JJ**, Donnenberg AD*, Zaia JA**, Santos GW*, and Saral R*
*The Johns Hopkins University, Baltimore, MD, USA
**City of Hope National Medical Center, Duarte, CA, USA

Objective. To evaluate the effect of combined modality therapy (AZT plus allogeneic BMT) on HIV-1 infection in a lymphoma patient with AIDS.
Methods. The patient, a 41 yo HIV-1 culture+ man with NHL, received cyclophosphamide and total body irradiation to ablate tumor, bone marrow and marrow derived cells. AZT (5 mg/kg q 4h) was begun 2 wks prior to BMT. Nine days after initiation of ablative therapy he received 4x10^8 nucleated BM cells/kg from his HLA identical sister. At this time AZT was reduced to 1.3 mg/kg q 4h and maintained at that level for the duration of treatment. HIV-1 was monitored by culture and polymerase chain reaction gene amplification (PCR, LTR and ENV, DNA and reverse transcribed RNA).
Results. Despite continuous AZT, engraftment was prompt (17 days to neutrophils>500/mm^3). Peripheral blood mononuclear cells and BM samples became HIV-1 negative by culture and PCR 32 days after BMT. The patient died of tumor relapse 47 days after BMT. Complete autopsy showed no evidence of HIV-1 by PCR (brain, BM, spleen, tumor, heart, kidney, liver, lung, colon) or culture (brain, BM, lymph node, tumor).
Conclusions. 1) The patient tolerated intensive therapy associated with BMT 2) Prompt engraftment was attained despite AZT therapy 3) PCR and culture data suggest clearance of host cells harboring virus and prevention of infection of repopulating donor cells.

W.B.P.321 EFFECT OF COMBINATION OF ZIDOVUDINE AND INTERFERON-ALPHA COMPARED WITH ZIDOVUDINE AND ACYCLOVIR ON HIV-ANTIGENAEMIA IN ASYMPTOMATIC PATIENTS

Weber, Rainer; Bonetti, A.; Lüthy, R.; Putzi, R.; Spacey, B.* and Siegenthaler, W.
Department of Medicine, University Hospital, Zürich, Switzerland; *Wellcome Research Laboratories, Beckenham, UK.

Objective: To assess the antiretroviral effect of zidovudine (AZT) in combination with either lymphoblast interferon-alpha (INF) or acyclovir (ACV) in asymptomatic HIV infected pts.
Methods: 15 pts in CDC stage II/III with positive p24 antigen were randomized to receive 12 weeks of AZT 2x250 mg/d and either ACV 2x800 mg/d or INF 1.5 Mu s.c. 3x weekly. Following a washout period of one month, 6 pts (pts 1,2,4,6,8,10) agreed to continue with a crossover phase. Antiretroviral activity was assessed by measuring serum p24 antigen levels.
Results: p 24 antigen levels (Abbott EIA) recorded as a coefficient were:

	AZT+INF		wash-	AZT+ACV	
	wk 0	wk 12	out	wk 0	wk 12
pt 1	11.35	1.63	|	4.74	4.45
pt 2	1.30	0.99*		1.92	0.99*
pt 3	2.50	1.14	|		
pt 4	2.13	1.28		1.87	1.87
pt 5	1.94	0.99*	|		
pt 6	3.94	1.01		2.37	NEG**
pt 7	1.50	1.42	|		

	AZT+ACV		wash-	AZT+INF	
	wk 0	wk 12	out	wk 0	wk 12
pt 8	5.52	3.37	|	9.07	4.46
pt 9	1.59	1.17			
pt 10	1.41	NEG**	|	2.73	1.29
pt 11	4.97	3.90			
pt 12	1.08	NEG**	|		
pt 13	2.86	1.23			

*0.99 = cut off
**NEG < 0.99
pts 14 and 15 discontinued due to side effects

P 24 antigen was transiently negative during AZT+INF at wk 1 and 6 in pts 2 and 7, respectively. Temporary mild neutropenia occurred in 3 pts with AZT+INF.
Conclusions: P 24 antigen declined in all pts with the above dose regimens. Preliminary results suggest a superior antiretroviral activity of AZT+ACV, but require dose range finding studies and continuation of treatment to evaluate clinical long term benefits.

W.B.P.323 AN OPEN-LABEL STUDY OF THE SAFETY AND EFFICACY OF CO-ADMINISTRATION OF ZIDOVUDINE AND RECOMBINANT IFN-BETA.

Borucki, Michael J. and Pollard, R.B.. Division of Infectious Diseases, University of Texas Medical Branch at Galveston. U.S.A.

Objective. A phase I study of the long-term tolerance of recombinant interferon-beta-ser (Betaseron) at doses of 45 or 90 million units when administered subcutaneously on a daily basis to HIV-infected individuals receiving 200mg of Zidovudine (ZDV) every four hours.
Methods. Seventeen patients who had previously been maintained on ZDV alone, for standard indications, were enrolled in the study; 8 patients at 90 million and 9 patients at 45 million units per day (MU/D).
Results. Seven of the 17 patients have terminated from the study; 1 expired, 4 of the remainder terminated due to local skin reactions and/or systemic symptoms such as fevers and malaise. Four of 8 patients enrolled at 90 MU/D underwent dosage reduction, 3 of these secondary to increased hepatic transaminases. In the entire group, an overall two-fold increase in transaminases was seen, which peaked at 12 to 16 weeks of therapy. Other toxicities, particularly myelotoxicity (1 of 17 patients) were infrequently observed. The total white blood cell counts after 36-44 weeks of therapy were approximately equivalent to the patients' entry values. An AIDS-associated opportunistic infection or neoplasm occurred in 7 patients.
Conclusion. Full-dose ZDV and Recombinant-IFN-Beta-ser at doses of 45 to 90 million units/day are well tolerated for periods in excess of 40 weeks. Unlike IFN-alpha, patients receiving IFN-beta tolerated full dose ZDV well, without significant myelotoxicity. Prospective, controlled studies are needed to assess the efficacy of this combination.

W.B.P.320 AS 101 IN ASSOCIATION WITH AZT IN AIDS PATIENTS : A PHASE I PILOT STUDY.

J.Ph.LAPORTE*,J.FROTTIER*, D. DUMONT**, J.C.IMBERT*, M.ALBECK***,A. NAJMAN* et al.
* St Antoine Cooperative Group on AIDS 75012 PARIS FRANCE
** Centre de Recherches du Service de Santé des Armées, antenne CRA Fontenay aux roses FRANCE
*** Bar Ilan University, Ramat Gan ISRAEL

Interesting clinical and biological results have been obtained with AS 101 (a new immunomodulating agent, Nature 1987,330:173-176) in AIDS patients. However in an effort to further improve patients with advanced disease, we tried to associate AZT with AS 101. 5 patients (all male - median age 30 y ; range 26-37) stage IV entered the study. AS 101 and AZT were given respectively ; IV 5 mg/m² x 3/week and per os 1 gr/day. 4/5 have had previous toxicity of AZT (severe pancytopenia). Results : one patient with pulmonary Kaposi sarcoma died from progression of K. S. .The 4 others patients are alive. The median duration of the association was 3 months (3-5). We did not observe any clinical sign of intolerance. 1 patient experienced neutropenia and AZT was stopped. Hematological tolerance in the 3 other patients was good. 1 patient increased ASAT or ALAT level but he had tuberculosis of the liver. We observed no change of the other biological parameters. In 3 patients the clinical status improved. Further data of AS 101-AZT association will be provided.

W.B.P.322 ZIDOVUDINE VS. ALPHA INTERFERON VS. THE COMBINATION IN PATIENTS WITH EARLY HIV INFECTION.

Zunich, Kathryn M.; Davey,V.; Metcalf,J.A.; Masur,H.; Fauci, A.S.; Lane,H.C.; et al. National Institutes of Health, Bethesda, MD, USA.

Objective. To compare the effects of zidovudine (AZT), alpha interferon (αIFN), and a combination of these 2 drugs in delaying the progression of HIV disease.
Methods. HIV-infected persons with >500 CD4+ cells/mm3 and no history of opportunistic infection (OI) are being entered in this trial. Following a screening evaluation that includes HIV serology, HIV culture, p24 antigen, polymerase chain reaction (PCR), and immune profile, patients are randomized to either AZT alone (200 mg q4h), αIFN alone (5x10^{6}u qd x 2wks then increase as tolerated), or a combination of the 2 (AZT 100 mg q4h + αIFN 1x10^{6}u qd x 2wks then increase as tolerated). End point criteria include a decline in CD4+ cells to < 200/mm3 or the first occurrence of an AIDS-defining OI.
Results. The patients enrolled thus far (n=30) have a mean age of 35 (26-49) and a mean CD4 count of 696 cells/mm3 (515-1293). Eight of 30 have had a positive (+) culture for HIV and 2/30 have been p24 antigen +. Utilizing primer pairs from env, LTR and gag regions, 26/28 have been + by PCR.
Conclusion. Patients with early HIV infection and CD4+ cells >500/mm3 almost uniformly have demonstrable virus by PCR testing. However, HIV culture and p24 antigen are generally negative, suggesting that the patients have a low viral burden. The data generated over the next 6 months should permit an evaluation of the relative toxicities and a preliminary evaluation of the efficacies of AZT, αIFN, and the combination in delaying the progression of HIV disease.

W.B.P.324 EFFECT OF A COMBINED DEXTRANESULFATE/ZIDOVUDINE THERAPY COMPARED TO ZIDOVUDINE MONOTHERAPY IN AIDS

BROCKMEYER N.H., MERTINS L., GOOS M.
Dept. of Dermatology, University of Essen, FRG

18 HIV infected patients (status WR 6) were randomly attached to a combined dextranesulfate (1800 mg/d)/ zidovudine (800 mg/d) therapy (DZ) or a zidovudine (800 mg/d) monotherapy (Z). Each group consisted of 9 patients, age 23 to 35 years, with equivalent amounts of CD4+ lymphocytes in both groups prior to therapy. Before and every 8 weeks during the treatment period we performed a complete history and physical examination, standard medical tests of enzymes, kidney, liver and blood parameters, isolation and enumeration of lymphocytes and lymphocyte subsets, assessment of complement components, immunoglobulins and immune complexes in serum as well as measurement of in vitro lymphocyte blastogenic response to mitogens.

Evaluation of the first 6 months of the study revealed 1 relapse of pneumocystis carinii pneumonia in each group. No alterations were found concerning the individual HIV antibodies and p24 antigen levels. Apart from an initially more profound improvement of immunostatus after 8 weeks of DZ compared to Z there were no differences between the two groups within the first 6 months of study. Dextranesulfate application did neither enhance adverse drug effects of zidovudine nor induce severe disorders of blood coagulation. The study is still in progress.

W.B.P.325 THE SAFETY OF ZIDOVUDINE AND INTERLEUKIN 2 IN ASYMPTOMATIC HIV INFECTED PATIENTS

Bartlett, John A.; Blankenship, K.D.; Greenberg, M.; Tyler, D.S.; Weinhold, K.J. and the ACTG; Duke University Medical Center, Durham, NC, U.S.A.

Objective: To study the safety of combining zidovudine (ZDV) and interleukin 2 (IL2) in patients with asymptomatic HIV infection.
Methods: Patients with WR2 HIV infection were given ZDV 200 mg po 5x/day for 8 wks, 4 wks of both ZDV and 100,000 u/m^2 IL2 qd, and finishing with 8 wks of ZDV alone. Four patients have completed the study; additional patients at higher IL2 doses will be included.
Results: All developed mild hematologic toxicity; mean HGB fall 0.5 gm/dl and mean WBC fall 500/mm^3. One patient developed transient neutropenia (nadir=912/mm^3) at wk 12. Non hematologic toxicity essentially occurred only during IL2. Two patients developed fevers, 1 chills, 1 myalgias and 1 nausea. One additional patient was dropped due to severe nausea at wk 2. Absolute CD4 counts fell over the 20 study wks (mean -146/mm^3) but during the 4 wks of ZDV and IL2 rose transiently (mean +360/mm^3). Interestingly, using in vitro assays virus-specific non-MHC restricted cellular cytotoxicity, NK activity and LAK activity were significantly augmented in all 4 patients during IL2 administration, and have remained elevated in 1 patient. One patient was p24 Ag and virus culture positive at entry; both remained positive throughout the study. No patient became antigenemic or viremic during IL2.
Conclusions: ZDV and IL2 are well tolerated by patients with asymptomatic HIV infection. IL2 related toxicities were minor and the mild hematologic toxicity of ZDV was not worsened by IL2. Reactivation of latent HIV infection did not occur with IL2 in the presence of ZDV as assessed by stable CD4 counts, p24 Ag levels and virus cultures. Given the promising evidence of stimulated immunologic reactivity, this combination deserves further clinical study.

W.B.P.326 COMBINED TREATMENT WITH ZIDOVUDINE AND LYMPHOBLAST INTERFERON ALPHA IN PATIENTS WITH HIV-RELATED KAPOSI's SARCOMA

[illegible], Reinhard, for the Swiss Clinical Task Force on AIDS
Department of Medicine, University Hospital of Zürich, Switzerland

Objective: To assess efficacy and side effects of combination therapy with low dose zidovudine (AZT) and lymphoblast interferon alpha (IFN) in patients (pts) with AIDS-related Kaposi's sarcoma (KS).
Methods: In an ongoing study 16 homosexual HIV-positive men with histologically confirmed KS are treated initially with 10 MegaU IFN/d s.c. and 2 x 250 mg AZT/d. Evolution of KS (CR = disappearance of all lesions, PR = ≥ 50% of lesions resolved, MR = minor remission, <50%), adverse effects, immunological parameters and effect on p24-antigenaemia are assessed. Follow up ranges from 4 weeks to 8 months.
Results: 11/16 pts responded: 2 pts with CR, 2 pts with PR, 4 pts with MR, 3 pts with stabilisation of progressive disease. No effect was noted in 5/16 pts: 3 pts had progressive disease, KS-lesions were unaffected in 2 pts.
P24-antigenaemia was present in 10 pts at the beginning of the study, p24 became undetectable in 7 pts, 5 of them showed also tumor regression. No substantial rise in CD4 counts was noted.
Marked anemia (< 10g/dl) occurred in 8 pts, minor decreases in hemoglobin developed in all other patients. Neutropenia (0.6<PMN<1.2 [x10^9/l]) was observed, but required no dosage modifications. Alterations in liver function tests were frequent, but less than 2 times base line values. No effect was seen on platelet counts, electrolytes and renal function. Full dosage was tolerated by 2 pts for 3 and 6 months, respectively. In 5 pts IFN dose was reduced because of adverse experiences attributable to IFN (3 pts) and anemia (2 pts). Treatment duration after dose adjustment ranges from 3 to 4 months.
Conclusions: Antitumor as well as antiretroviral effects of combined AZT/IFN-treatment can be demonstrated at considerably lower doses than used in previous trials. However, progressive anemia is a limiting factor and adverse effects attributable to IFN require further dose range finding studies.

W.B.P.327 LONG-TERM (18 MONTH) TREATMENT OF SEVERE HIV INFECTION WITH AN ALTERNATING REGIMEN OF AZT AND 2',3'-DIDEOXYCYTIDINE (DDC)

Yarchoan, Robert; Pluda JM; Thomas RV; Perno CF; McAtee N; and Broder S.
Clinical Oncology Program, National Cancer Institute, Bethesda, Maryland, USA.

Objective. AZT and ddC are 2 pyrimidine dideoxynucleosides (ddN) with activity against HIV and different limiting toxicities. AZT can cause bone marrow suppression, while continuous high-dose ddC can cause painful peripheral neuropathy after 6 to 11 wks. We explored whether an alternating regimen of AZT and ddC would reduce toxicity from both drugs.
Methods. 18 patients (pts) with AIDS or poor-prognosis ARC (median 118 T4 cells/mm3 at entry) were given AZT (200 mg orally every 4 hrs for 7 days) alternating with ddC (0.03 mg/kg every 4 hrs [10 pts] or every 8 hrs [8 pts] for 7 days).
Results. Of the 18 pts, 9 are on the original regimen 42-85 wks after entry (mean 61 wks) without developing substantial toxicity. Of the 9 pts who were taken off, 4 developed complications of HIV infection (1 *M. avium* sepsis, 1 lymphoma, 1 thrombocytopenia, 1 increased KS) and 5 pts developed drug toxicity (1 rash at wk 5, 1 arthralgias at wk 10, and 3 neuropathies at wks 25, 27, and 61). One pt died of KS; 16 are known to be alive. In pts receiving ddC every 4 hr, mean T4 cells increased 62/mm3 above entry at wk 18 ($p<0.05$) and were still 40/mm3 above entry at wk 54. In pts receiving ddC every 8 hr, the mean T4 cells were 38/mm3 above entry at wk 18 (wk 54 data not available as the 1st 10 pts entered received ddC every 4 hr). Serum HIV p24 Ag declined substantially in both groups. Overall, pts noted increased energy upon starting the regimen and gained a mean of 3.9 kg by wk 24.
Conclusion. Alternating regimens of AZT and ddC can be tolerated for at least 18 months in some pts. The regimens have clinical activity against HIV and appear to be less toxic than either drug used alone.

W.B.P.328 DAILY SUBCUTANEOUS RECOMBINANT GRANULOCYTE-MACROPHAGE COLONY STIMULATING FACTOR IMPROVES THE NEUTROPENIA INDUCED BY AZIDOTHYMIDINE IN PATIENTS WITH AIDS/ARC; Follow-up.

James D. Levine, J.D. Allan, J.H. Tessitore, N. Falcone, R. Israel, J.E. Groopman, New England Deaconess Hospital, Harvard Medical School, Boston, MA 02215; Schering Laboratories, Kenilworth, NJ U.S.A.

OBJECTIVE - To determine safety and efficacy of subcutaneous recombinant Granulocyte-Macrophage Colony Stimulating Factor in patients with AZT induced Neutropenia.
METHODS - We have studied the use of once daily subcutaneous (GM-CSF) in 17 patients who developed neutropenia (<1000 Neutrophils) on full dose (1200 mg/d) AZT therapy.
RESULTS - Prior to beginning rGM-CSF, the mean neutrophil count was 790 (range 378-1023) and the mean T4 count was 38 (range 0-139). 14/17 patients required 1.0 mcg/kg/d rGM-CSF to maintain an absolute neutrophil count (ANC) of >1000. 2/17 required 3.0 mcg/kg/d and 1/17 required 5.0 mcg/kg/d. ANC was >1000 (mean 3111 - range 1376-7476) within one week in 15/17 patients. There was no stimulation of HIV by serum p24 antigen or culture of peripheral blood mononuclear cells. 14/17 patients required red cell transfusions for AZT induced anemia. Toxicities were mild and included fever responsive to ibuprofen 11/17, erythema at the injection sites that resolved after continued use in 14/17 and thrombocytopenia (platelet count <50,000/ul) in 5/17. There was one episode of OI (PCP) and 3 episodes of documented bacterial infections (2 with ANC >1000/ml one with ANC 225/ml). All responded to appropriate therapy.
CONCLUSION - rGM-CSF is well tolerated in patients who become neutropenic on full dose AZT.

W.B.P.329 THE USE OF AN ALTERNATING REGIMEN OF AZT AND SUBCUTANEOUS (SC) GM-CSF IN PATIENTS WITH SEVERE HIV INFECTION AND LEUKOPENIA

Pluda, James M*; Yarchoan, Y*; McAtee, N*; Thomas, .*; Oette, D**; Broder, S*. * NCI, Bethesda, Md, USA, ** Sandoz Research Institute, East Hanover, NJ, USA.

Objective. To evaluate the toxicity and activity of an alternating regimen of AZT and GM-CSF in patients (pts) with severe HIV infection and leukopenia.
Methods. SC GM-CSF was administered to four pts who had used prior AZT and 5 who had not on a continuous basis 3 times a day for 12 days. Following a 2 day rest period, 200mg of AZT orally every 4 hours was given for 7 days, followed by 5 days of SC GM-CSF as before, followed by a 2 day rest period. This 14 day cycle was administered repeatedly.
Results. During the initial 12 days of continuous GM-CSF, there was an increase in serum HIV p24 antigen (1413 ± 1195 pg/ml at wk 2 vs. 505 ± 384 at entry, $p=0.05$) in each of 6 patients who had detectable levels. Subsequently, these levels fell on AZT. All pts had significant elevations in their leukocyte counts while on GM-CSF. During alternating therapy, the WBC increased during GM-CSF and declined on AZT. Pts' Hgb values declined, and their MCV's rose, but less than was reported using continuous AZT alone. The T4 cells in pts with no prior AZT treatment rose significantly ($p=0.05$), while those with prior AZT usage did not. Toxicity from GM-CSF was minimal and the regimen was well tolerated. Most pts reported improvements in their sense of well-being.
Conclusion. GM-CSF given SC increased WBCs in pts with severe HIV infection and leukopenia. However, an increase in HIV p24 Ag was seen after 2 weeks of continuous GM-CSF. When GM-CSF was then given alternating with AZT, there was less hematologic toxicity than seen with full dose AZT. Also, rises in T4 counts were seen, particularly in pts with no prior AZT use. Combination therapies with concurrent GM-CSF and AZT may be worth exploring further.

W.B.P.330 AUGMENTATION OF NON-MHC RESTRICTED CELLULAR CYTOTOXICITIES IN PATIENTS RECEIVING ZIDOVUDINE PLUS INTERLEUKIN 2

Weinhold, Kent; Tyler, D.; Austin, A.; Lyerly, K.; Bolognesi, D., Bartlett, J., and the ACTG. Duke University Medical Center, Durham, NC, USA.

Objective. To correct defects in cellular cytotoxicities among asymptomatic HIV-1 infected individuals by administration of IL-2.
Methods. Patients entered onto ACTG Protocol 042 received 200mg Zidovudine (ZDV) orally 5 times daily for 21 weeks. During weeks 9-12, patients received 10^5 BRMP units/M^2 of recombinant IL-2 by I.V. bolus injection. At specific timepoints before, during and after IL-2 administration, peripheral blood mononuclear cells (PBMC) were obtained and tested for cytotoxic reactivity in 6-hr ^{51}Cr release assays against gp120 expressing cells as well as K562 (NK) and Daudi (LAK) targets.
Results. Administration of recombinant IL-2 produced significant augmentation of HIV-1 gp120 specific non-MHC restricted cytotoxicity in all 4 patients. Peak levels of cytotoxicity were observed between the first and second weeks of IL-2 administration. Parallel increases in NK and LAK activities were observed. Augmentation was transient and apparently not linked to significant changes in CD16$^+$ effector cell populations. Slight improvements in the proliferative responses to mitogens and/or recall antigens were noted in a few of the patients.
Conclusions. Administration of IL-2 produces a significant increase in generalized cytotoxic reactivities in the absence of any overt toxicities. The augmentation is, most likely, due to a transient correction of an effector cell defect which appears early in the course of HIV-1 infection.

W.B.P.331 ZIDOVUDINE (AZT) TREATMENT OF THE AIDS DEMENTIA COMPLEX (ADC): RESULTS OF A PLACEBO-CONTROLLED, MULTICENTERED THERAPEUTIC TRIAL

Price, Richard W; Koch, MA; Sidtis, JJ; Feinberg, J; Collier, A; Kennedy, C; Singer, E; Price, S; and AIDS Clinical Trials Group, NIAID, Bethesda, MD, U.S.A.

Objective: To determine the efficacy of AZT in alleviating mild to moderate ADC in HIV-1-infected patients with relatively preserved $CD4^+$ cells.
Methods: 40 patients with mild to moderate ADC from 9 centers were randomized to 3 treatment arms: AZT 400mg 5/day, AZT 200mg 5/day, or placebo 5/day. We report the results of preliminary analysis of the initial 16-week phase of the trial comparing the 2 AZT groups (which remain blinded) to the placebo group. Therapeutic efficacy was evaluated using standardized neurological assessments and 8 "screening" neuropsychological tests.
Results: This phase of the trial was administratively aborted before the planned accrual. 27 patients completed 8 weeks and 24 completed 16 weeks of the trial; 12 patients were prematurely terminated when the trial was aborted while 2 suffered adverse events and 4 withdrew from the study. The 3 groups were well balanced with respect to baseline parameters including $CD4^+$ counts (entry mean, 525). While there was no appreciable change in the overall classification of ADC severity across the 3 groups and individual test comparisons were significant ($p<.05$) in only 2 of 8 neuropsychological tests at 16 weeks, the placebo group exhibited the least favorable change in 7 of the 8 tests at 8 weeks and in all 8 tests at 16 weeks.
Conclusion: Despite the small sample size, these data support a therapeutic effect of AZT in improving neuropsychological performance in ADC patients. Further analysis will be needed to determine whether this is dose-related.

W.B.P.333 SURVIVAL OF PATIENTS WITH HIV DISEASE TREATED WITH ZIDOVUDINE (AZT)

Shepp, David; Kaplan, M; Muggeo, C; Smith, M; Lesser, M.
Cornell U. Medical College, North Shore U. Hospital, Manhasset, NY., USA.

Objective. To determine the probability of survival in patients with HIV disease treated with zidovudine (AZT).
Methods. From 11/86 through 12/87, patients meeting current USFDA indications for treatment received AZT. Initial dose used was 1-1.2g/day with reductions made at the discretion of the physicians when patients experienced toxicity. Survival was calculated using Kaplan-Meier plots.
Results. 116 patients with the following characteristics were treated: 96 men, 20 female, 54 gay, 47 IVDA, 15 other risks, 100 white, 16 non-white, median age 35. The indication for treatment was AIDS in 60 and T-helper depletion (THD) in 56. The median follow-up was 68 weeks. Survival at 26, 52, and 78 weeks was 88, 76, and 64%, respectively. Median survival was 94 weeks. Patients with THD had better survival than those with AIDS (89 vs. 63% at 52 weeks, $p=0.02$). Among patients with AIDS, those starting AZT within 8 weeks of the AIDS-defining OI survived better than those starting later (80 vs. 44% at 52 weeks, $p<.01$). When those starting later were excluded, survival was 92, 84 and 76% at 26, 52 and 78 weeks. Survival was not different when analyzed by sex, risk factor, or age ≥ 40. A trend toward worse survival in non-whites did not reach significance.
Conclusion. This study provides survival data useful for prognostication in patients treated with AZT according to current practices. Because survival is improved in those treated for THD or early after diagnosis of AIDS, initiation of AZT therapy should not be delayed.

W.B.P.335 A PHASE I/II TRIAL OF THE COMBINATION OF ZIDOVUDINE AND INTERLEUKIN-2 IN THE TREATMENT OF HIV-RELATED KAPOSI'S SARCOMA

Kovacs, Joseph A.; Davey, R.; Polis, M.; Zunich, K.; Fauci, A.S.; Lane, H.C.; et al.
National Institutes of Health, Bethesda, Maryland, USA.

Objective. To evaluate the toxicity and efficacy of the combination of zidovudine and interleukin-2 in the treatment of HIV-infected patients with Kaposi's sarcoma. Methods. In an open study, patients with HIV infection documented by ELISA, western blot, or culture, and biopsy-documented Kaposi's sarcoma were begun on zidovudine 200 mg q4H. After six weeks, the patients were begun on continuous infusions of IL-2 for 3 weeks, during which time zidovudine therapy was continued. Groups of three patients were enrolled at increasing doses of IL-2, beginning at 250,000 U/d, until the the maximum tolerated dose was determined. The combination of drugs was evaluated for toxicity and efficacy by weekly monitoring of routine blood values, including CBC and chemistries, as well as CD4 count, p24 antigen and HIV cultures. Results. Three patients have completed the study to date, all at a dose of 250,000 U/d of IL-2. No significant toxicity has been seen, although 1 patient had recurrent bacteremia due to infected central lines. No significant immunostimulating or anti-retroviral effects have been seen at this dose of IL-2. Two patients remained HIV culture positive, and 1 patient with p24 antigenemia had no change in antigen levels during IL-2 therapy. Conclusions. IL-2 can be safely administered at a low dose in combination with zidovudine. Completion of the study will determine if higher doses of IL-2 can also be safely administered, and if there is a beneficial effect seen during combination therapy.

W.B.P.332 STUDY COMPLIANCE AMONG ASYMPTOMATIC HIV SEROPOSITIVES (ASX HIV+) BEING TREATED WITH AZIDOTHYMIDINE (AZT)

Jacobsen, Paul B; Vassalos, C.; Brown, D.; Gorfinkle, K.; Philogene, G.; & Polsky, B. Memorial Sloan-Kettering Cancer Center, New York, New York, U.S.A.

Objective. To measure compliance and identify factors related to degree of compliance among participants in an experimental trial of the efficacy of AZT in preventing/slowing the development of AIDS.
Methods. Twenty (19 male, 1 female) ASX HIV+ enrolled in a double-blinded, placebo controlled trial in which 5 doses (3 capsules each) per day of high or low dose AZT or placebo were prescribed (ACTG Protocol 019) completed daily forms assessing missed doses and physical symptoms for an average of 60 days (Range=10 to 162) and underwent brief psychological assessment.
Results. Subjects reported missing an average of 6% (Range=0-24%) of all doses. Average number of missed doses per day was approximately 1 of 15 capsules, with the last dose of the day the most frequently missed - average of 13% of the time. No subject dropped out or reported using other nonprescribed treatments during the period of study. More missed doses was significantly ($p<.05$) correlated with younger age, nausea, diarrhea, psychological distress, and health beliefs.
Conclusions. Data from one center indicate that, while drop-out among ASX HIV+ enrolled in a placebo-controlled AZT study is not encountered, missed medication doses are common. Patient self-monitoring provides a useful means of estimating missed doses and investigating the determinants of noncompliance.

W.B.P.334 Reduction of Zidovudine Side Effects by an intermittent Therapy Scheme

Staszewski S., Odewald J., Gottstein A., Rehmet S., Helm E.B., Stille W., Universitätsklinik Frankfurt, Zentrum der Inneren Medizin, Infektions-Ambulanz, FRG

In a dosage from 1000 - 1200 mg/d, Zidovudine (AZT), in spite of its life prolonging effect, causes myelotoxic side effects. By an intermittent therapy scheme with a drug-free regeneration period, these side effects on hematopoesis might be avoided.
We therefore report on 16 patients (7 AIDS, 9 ARC) with an intermittent AZT regimen. Therapy scheme consits of application intervalls (AI) of 4 wks (1000 - 1250 mg/d), followed by a 4 weeks' break. At present, 16 patients have finished 2 AIs, and of these, 10 pts. have finished 3 AIs. Total observation time is 176 ds (median); min. 120, max 254 ds. Initial symptoms (nausea, headaches) mainly occured during 1st. AI and in only 2 cases also at early 2nd AI. Mean body weight increased > 10 % of inital value (from median 59 to 67 kg). Also the patients' physical and mental abilities increased significantly. CD4+ cell count increased by 37 % (median) after 1st AI, by 7 % after 2nd AI. During 3rd AI, it went down to initial value. Hb and leucocytes were normal; anemia or leucopenia was not found. MCV was only slightly increased. Up to now, there have been no opportunistic infections nor death cases.
Conclusion: Intermittent AZT regimen, as continuous therapy, led to an increase in patients' well-being, and to transient increase in CD4+ cell count. However, the lack of any myelotoxic side effects was remarkable.

W.B.P.336 ZIDOVUDINE USE IN INTRAVENOUS DRUG USERS.

Slim, Jihad*, Perez, G., Forrester, C., Tonnesen, G. Johnson, E.S., Saint Michael's Medical Center, Newark, New Jersey, U.S.A.

Objective: To describe characteristics and effects of zidovudine usage in an intravenous drug user population.
Methods: A retrospective review of 43 patients studied from 2/87 through 7/88 who were followed bi-weekly in a clinic environment with complete cell counts (CBC) chemistry profiles and physical examinations.
Results: Seven patients never filled their prescriptions. Of the remaining 36 (30 males, 6 females) the mean duration of therapy was 6 months. CBC testing showed 14/36 with a significant decrease in white cell count, and 4/36 with a significant decrease in hemoglobin (all four with Mycobacterium Avium-Intracellulare infection). Subsequently 6/36 felt improvement with four showing greater than 10 pounds of weight gain, 7/36 had worsening of their condition with five developing Mycobacterium Avium-Intracellulare infection. No patients showed improvement in CD 4 cell counts and 50% showed decreases.
Conclusion: Leukopenia was the primary effect noted and Mycobacterium Avium-Intracellulare infection the principal documented reason for deterioration on therapy. Side effects however are comparable to those reported in the homosexual cohorts studied.

W.B.P.337 OUTCOMES OF TREATMENT WITH AZT OF PATIENTS WITH AIDS AND SYMPTOMATIC HIV INFECTION (ARC)

Cox, Patricia, MN; Martin, M, MN; Styer, C, MN, & Beall, GN, MD Dept Med, Harbor-UCLA Med Ctr, Torrance, CA, USA

Objective. To assess the effectiveness of AZT and the incidence of hematological toxicity in a standard clinical practice.
Method. A retrospective chart review of 101 patients with AIDS (73%) and ARC (27%) treated with AZT at a public hospital clinic in Los Angeles County. The patients have been followed for a mean of 7 months (range 1-20) by MD's and NP's. Initiation of AZT required a CDC-defined diagnosis of AIDS or an absolute CD-4 lymphocyte count of $<200/mm^3$. The AZT dose was 200 mg q4h.
Results. The patients are 60% Cauc., 21% Hisp. and 20% Blk., mean age 37 and predominant risk factor of homo/bisexuality (76%). After 7 months (mean) of AZT therapy, 77% of the patients survive, 18% are dead and 5% lost to follow up. Decrease in AZT dose due to anemia, neutropenia or both was necessary in 33 patients. Transfusions were required for 23. Five modified their dose for personal reasons. In most instances, (84%) the need for modification was permanent. Most of the patients who required dose modification had AIDS and/or CD4 lymphocyte counts $<150/mm^3$. AZT treatment had been carried out for an average of 11 months in the patients that died; most had already discontinued AZT.
Conclusion. Compared to historical controls, AZT prolongs life for patients with HIV infection. Drug toxicity and the progression of immunodeficiency limit survival.

W.B.P.338 AZT THERAPY IN INFECTED PEOPLE: EFFICACY AND SIDE EFFECTS.

Francesco Chiodo*, P.Costigliola*, E.Ricchi*, R.Borderi*, R.Manfredi*, A.Guariento**, P.Boni**
*Istituto Malattie Infettive; Universita' di Bologna - **Laboratorio Centralizzato; Policlinico S.Orsola-Malpighi - Bologna, ITALY

Objective. To study the efficacy and toxicity of long term administration of Zidovudine (AZT).
Methods. From August 1987 to December 1988, 40 HIV Ab +ve subjects with various clinical features (5 OI-AIDS, 2 SK-AIDS, 27 ARC-CDC IVa, 14 GF/PGL (WR5) were treated with AZT (10 mg/Kg/d) for an average period of 9 months.
Results and conclusion. Nine/40 patients (5 AIDS + 2 ARC) developed Opportunistic Infections during the treatment period. An important improvement of lymphocytes number was found in 26/40 patients, but the CD4+ cells have raised significantly in 10 patients. Clinical side effects occurred in 19 patients as follow: slight fever (11), nausea (7), headache (4), rash (4) and convulsions (2). The most important adverse reactions were haematologic - TABLE I. After 4 months five/25 patients needed blood transfusions for severe anemia and therapy became discontinue and then was stopped. A raise of MCV was seen in 20/25 subjects. Analysis of red cells volume hystogram showed a progressive appearance of a double peak picture due to the arise of a new population of red cells with higher size, although the average MCV could be within normal values. We underline the opportunity of including this analysis to monitorize the haematologic side effects of AZT therapy.

W.B.P.339 ZIDOVUDINE TREATMENT OF HIV INFECTION: CLINICAL&IMMUNOLOGICAL EVALUATION.

ME VALENCIA, MCG RODRIGUEZ, P LAVILLA, V PINTADO, A GIL, JJ VAZQUEZ. Hospital La Paz. Madrid. Spain.

Objective: To evaluate the effect of zidovudine in HIV infection.
Methods: 33 HIV-patients were included: 24 with AIDS and 9 with ARC. Mean age was 30 y (r:24-59). There were 24 IV drug abusers, 5 homosexuals, 2 bisexuals and 1 heterosexual contact. The AZT dose was 1.200 mg/d,adjusted to the haematologic parameters. The patients were divided in 2 groups: A) AIDS, B)ARC. The mean follow-up time was 20 weeks (8-28). A monthly clinical evaluation was performed and an immunological evaluation was done every 8 weeks.
Results: Group A) The incidence of tumors and infections was not significantly lower than previous treatment. 10 patients died (42%) (6 opportunistic infections, 2 progressive encephalopathy, 2 non-Hodgkin linphoma). A transient improvement in the immunological parameters in the 8th. week was observed with subsequent decrease to lower levels than pretreatment ($\bar{x}$ CD4 week 0: $111/mm^3$; $\bar{x}$ CD4 week 24: $39/mm^3$). Group B) Neither opportunistic infection nor tumors were seen. No patient died and the general clinical state was better than the beginning of treatment. There was an improvement in the immunological parameters during the first weeks followed by a impaired in the later weeks ($\bar{x}$ CD4 week 0:$165/mm^3$; $\bar{x}$ CD4 week.16: $466/mm^3$; $\bar{x}$ CD4 week 48:$253/mm^3$).
Conclusions: AZT did not show useful in the advanced disease. In previous stage it seems to be clinically effective, but it did not produced immunological improvement. It's necessary to establish a patient selection.

W.B.P.340 ZIDOVUDINA(AZT) TREATMENT IN AIDS AND ARC

Raise,Enzo;Vannini,V;Schiattone,M.L*, Pulsatelli,L*Gualandi*G Cioognani,A*Procaccio,L*Martuzzi,M*Dip.Infectious Diseases and Immunopathology Unit,Clinical Pathology,Maggiore Hospital,Bologna,Italy.

Objective.To evaluate efficacy of AZT (2.8mg/kg/q4h) on lymphocyte subset and antigenaemia(HIV1Ag) in an open controlled trial.
Methods. The study concerns 58 AIDS with Candida Esophagitis,P.Carinii pneumonia,chronic mucocutaneous ulcers due to HSV,AIDS dementia complex,Wasting Syndrome,disseminated CMV or Criptococcosis,and Toxoplasma encephalitis.Every pt. had at least two major infections associated.AZT treatment included also 54 ARC belonging to CDC group 4A or 4C2,with CD4<200mm3.Peripheral lymphocytes(PL) CD4 and CD8 determined by monoclonal antibody with Epics C cytofluorimeter and the optical density(OD) of HIV1Ag,by Abbott Elisa(cut-off 0.86±0.19),were evaluated before and during AZT treatment.
Results.AIDS cases:PL,CD4 and CD8 did not improve on AZT,but HIV1Ag showed significant reduction with 4-8 weeks from the beginnig of treatment (OD 0.28±0.35 v.s. 0.64±0.62;P>0.001,by the Wilcoxon's test for coupled data).53.3% of pts became HIV1Ag negative.ARC cases:an imrovement of CD4 was present on day 90 of AZT therapy(299±162 mm3 v.s.125±58,P>0.05)and HIV1Ag was reduced within 4-8 weeks (OD 0.12±0.05 v.s. 0.44±0.46,P>0.001).
Conclusion.AZT treatment determines a significant reduction of HIV1 antigenaemia in AIDS and ARC pts. with or without immunological improvement.

W.B.P.341 NEUROLOGICAL AND IMMUNOLOGICAL EVALUATION OF A PATIENT TREATED WITH AZT WITH ACUTE HIV INFECTION AND ENCEPHALOPATHY.

Zangerle, Robert*, Pohl, P.** Felber, S.** Fritsch, P.*
*Dept. of Dermatology, University of Innsbruck, Innsbruck, Austria; **Dept. of Neurology, University of Innsbruck, Innsbruck, Austria.

Objective: We describe a 30-year-old patient with signs of acute HIV infection treated with AZT because of persistent neurological dysfunction.
Methods: HIV serology, CD4 count, neopterin, β2 microglobulin, delayed hypersensitivity, MRI and neuropsychological evaluation regularly.
Results: A 30-year-old man with high risk homosexual behaviour months before was admitted with a one month history of severe weakness, lethargy, weight loss, mild fever, severe dysarthria and gait disorder. CSF revealed aseptic meningitis. MRI showed high signal intensity on T2 weighed images in the white matter of the cerebellum. A CT-scan was normal. HIV serology was repeatedly inconclusive for one month (only p 17 in WB) and thereafter positive. Immunological evaluation showed an immunosuppressed patient (WR 4). Because of the severity of the neurological dysfunction (AIDS dementia complex, stage 2) with corresponding findings in the MRI, AZT was started. In the following months, he slowly recovered clinically and immunologically (WR 1); even the MRI findings seem to be slightly improved.
Conclusions: (1) Persistent encephalopathy could follow seroconversion. (2) AIDS dementia complex and meningoencephalitis of acute HIV infection could be difficult to differentiate. (3) Immunological markers could be markedly changed during seroconversion and improve thereafter possibly under the influence of AZT.

W.B.P.342 FOLLOW UP AND TREATMENT OF 58 HIV-INFECTED PATIENTS IN GREECE.

Stergiou, G.D.*; Ploumidis, G.M.*; Papadopoulos, A.I.*; Roumeliotou, A.N.**; Georgopoulou, S.A.*; Papaevangelou, G.L**
*1st IKA Hospital, Athens; **National Center of AIDS, Athens, GREECE

Objective: To present our experience from the follow up and treatment of 58 patients with HIV-infection in Greece.
Method: 58 patients with AIDS or ARC were studied, according to their clinical and laboratory findings, their CDC classification, their course in a period of 9 months, their response to treatment with AZT and their adverse reactions to therapy. AZT was administered to all patients with AIDS (14 subjects) and to those with ARC and a T4-lympocyte count <200 (10 subjects), initially at a dose of 1000 mg qd p.os which was gradually reduced to 300 mg qd within 6 months. The group of patients with AIDS consisted of 3 patients with P.carinii pneumonia, 5 with disseminated M.tuberculosis infection, 3 with HIV encepalopathy and 3 with Kaposi's sarcoma.
Results: The study lasted 9 months. The patients tolerated AZT well. Five of them showed a decrease of their Hct that led to early dose reduction and required multiple blood transfusions. Six patients with AIDS and all with ARC showed a clinical improvement.
Conclusions: 1. The patients in good physical condition and normal haematologic profile responded favorably to AZT.
2. The AZT-induced anemia was not severe enough to prevent us from administering the drug.
3. The platelet count was not significantly altered.
4. The 34 patients with ARC, who did not receive AZT showed a clinical deterioration but never fulfilled our criteria for administering AZT.

W.B.P.343 UPDATE ON AZT THERAPY IN AN INNER CITY POPULATION.

Samuels, Jonathan*, Hendrix, J. Hilton, M., Sloan, V., and Small, C.B. North Central Bronx Hospital/Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, New York, U.S.A.

OBJECTIVE: To evaluate efficacy, toxicity and compliance (comp) with AZT therapy among patients (pts) of poor, minority and intravenous drug use (IVDU) background in a clinic in New York City.
METHODS: Prospective data was derived on all AIDS and ARC pts on AZT for at least 4 weeks from 7/87-1/89.
RESULTS: 99 pts were evaluable:75 males,24 females;64 hispanic,25 black,8 white, 2 Asian: IVDU 59,homosexual 18,heterosexual contacts 15,transfusion 1, no known risk 6; 72 AIDS,27 ARC with low CD4(mean 138);mean age 35(range 22-59): mean Hct 34.3(range 21-54),WBC 4400(range 1.8-10.7);baseline mean Karnofsky score 83.6(range 50-100). 87/99(88%) were comp and received AZT for a mean of 30.3 wks(range 2-95 wks) total 2636 pt wks. All pts eventually received PCP prophylaxis. 57% had ≥1 adverse drug reaction (ADR) requiring dose reduction (44%) or cessation(13%). ADRs included: anemia 37%(18% required transfusion): leukopenia 33%: GI complaints 29%: headache 14%: fever 11%: rash 5%. Rates of anemia,transfusion,leukopenia,myalgias and insomnia were comparable, and nausea and headache less frequent than in published studies of other populations ($p<.05$). 83/87(95%) comp pts tolerated AZT for ≥ 4 wks. 17 opportunistic infections (OIs) occurred in 14/83 pts(17%) at mean of 35 wks (range 6-63 wks). 13/17(76%) OIs occurred in pts on reduced AZT. 6/83(7%) comp pts died (only 1 on full-dose AZT) vs 9/16(56%) noncomp or intolerant pts ($p<.05$). 85% of pts kept > 75% of clinic appointments: 10% kept 50-75%: only 5% kept < 50%.
CONCLUSION: AZT can be administered to IVDUs and others in inner city clinic settings with acceptable efficacy, tolerance and compliance.

W.B.P.345 EXPERIENCE WITH ZIDOVUDINE IN A CITY HOSPITAL AIDS CLINIC

Miller, Laurel ; Peterson, K; Davidson, A; Cohn, D;
Denver Disease Control Service, Denver, CO, USA

Objective: To evaluate the efficacy and toxicity of zidovudine (AZT) in patients (pts) with AIDS and ARC at Denver Department of Health and Hospitals (DHH).
Methods: A retrospective chart review of clinic and hospital records at DHH was done for all pts started on AZT between Nov. 1986 and June 1988. Follow-up was obtained through Dec. 1988. Product limit method was used for survival analysis (SA). Pts analyzed included those who survived >60d after Pneumocystis pneumonia in both the AZT and pre-AZT periods.
Results: A total of 137 pts received AZT, 11 for less than 28d. Of the remaining 126, 93 had AIDS and 33 ARC at the time of initiation of AZT. AIDS pts were diagnosed 0-608d (mean 83d) before starting AZT, ARC pts 0-1121d (mean 160d). Pts took the drug for 35-580d (mean 254d). Of 126 pts, 81(64%) experienced at least one adverse event (AE) requiring dose adjustment (mean 2.7 AE, range 1-10AE). AE included granulocytopenia (90), anemia (57), thrombocytopenia (4), malaise (18), GI intolerance (16), fever (10), rash (8), CNS effects (7), headaches (5). Of 126 pts, 27 (21%) required blood transfusions (range 2-12 units, mean 5 units/pt). AZT was discontinued (DC) in 31 pts (25%) 41-580d after initiation (mean 182d). Reasons for DC included malaise (6), granulocytopenia (5), GI intolerance (4), fever (3), other myelosuppressive treatment (6), hospice placement (4). Of the AIDS pts, 24 were followed from diagnosis to death at DHH and were hospitalized 0-8 times (mean 2.9). Twenty nine similar pts previously studied at DHH from 1982 through 1986 (pre-AZT) were hospitalized 1-16 times (mean 3.1). SA showed mean survival of 333d in pre-AZT pts compared to 593d in the AZT pts ($p<0.01$).
Conclusions: AZT significantly prolongs survival in AIDS pts although it is associated with frequent side effects leading to dose adjustments and DC of therapy. A retrospective analysis reveals no decrease in the number of hospitalizations since AZT has become available.

W.B.P.347 BENEFITS OF AZT WHEN STARTED AT INCREASING TIMES AFTER AIDS/PCP DIAGNOSIS.

SD Nightingale, SM Pounders, V Orcutt, B Collins & JD Jockusch. Parkland Memorial Hospital, Dallas, TX, USA.

The survival of 172 patients who had PCP at AIDS diagnosis and received AZT was compared, by a retrospective case control analysis, to survival of 149 controls who had PCP at AIDS diagnosis but never received AZT. Case survival was calculated from day AZT was begun or day of AIDS diagnosis, whichever came later. Control survival was calculated from day after AIDS diagnosis its matched case started on AZT. Survival of subjects who received aerosolized pentamidine (AP) was censored at the day AP was begun. We specifically examined the difference in survival between cases and controls as a function of how long after AIDS/PCP the cases were started on AZT:

Days After PCP AZT Begun	N	Case Survival	Control Survival	P (Wilcoxon)
0-90	88	508	172	<.03
91-180	37	681	157	<.02
181-270	17	411	59	<.001
271-365	13	189	195	NS
>365	17	210	123	NS
All Cases	172	411	158	<.0001

Within the limits of a retrospective case-control method and in the population studied, a statistically significant benefit of AZT was found only in the subset that began AZT within 270 days of AIDS/PCP.

W.B.P.344 DEVENIR DE 365 MALADES ATTEINTS D'ARC OU DE SIDA ET TRAITES PAR AZT PENDANT 4 A 18 MOIS

*Eric Dournon, Matheron S. Rosenbaum W. Michon C. Perronne C et Groupe D'Etude de l'AZT. Hopital Claude Bernard, Paris, France

Objectif. Apprécier à moyen et long terme l'activité de l'AZT.
Méthodes. 365 malades atteints d'ARC (80) ou de SIDA (285) depuis 0.5 à 36 mois (médiane 4) ont été inclus dans cette étude prospective. La posologie initiale a été de 200 mg/4h chez 260 malades, de 200 mg/8h chez 105 en raison de leur état hematologique. L'age moyen était de 36 ans (extrêmes: 20-66). 71.5% des malades étaient homosexuels. Parmi les malades atteints de SIDA, 19 avaient un sarcome de Kaposi (SK) isolé, 190 une ou plusieurs infections opportunistes (IO), 72 un SK et une ou plusieurs IO, 2 un lymphome, 2 une encephalopathie VIH. Au début du traitement le nombre de T4/mm^3 était de 75±90 chez les SIDA, 140±105 chez les ARC. Le recul moyen depuis le début de l'AZT est de 50 semaines (médiane 40, extrêmes 24-77) pour les ARC et 59.4 semaines (médiane 60, extrêmes 16-78) pour les SIDA.
Résultats. Chez les ARC, 6 SK, 3 lymphomes et 27 IO sont apparus 27.4±16.3 semaines après le début de l'AZT. Dix (12.5%) malades sont décédés. Parmi les 32 malades suivis pendant ≥ 52 semaines (médiane 58), 9 (28.1%) sont morts, 8 (25.0%) sont au stade de SIDA. Chez les malades atteints de SIDA, 281 IO (chez 162 malades), 18 lymphomes, et 23 SK sont apparus et 56 des 91 SK préexistants se sont aggravés. Au total, 115 (40.4%) malades sont morts et 106 (37.2%) se sont aggravés. Chez les 213 malades suivis ≥52 semaines, sont apparus: 242 IO (chez 135 malades), 15 lymphomes et 18 SK: 44 (81.5%) des 54 SK préexistants se sont aggravés. 105 (49.3%) de ces malades sont morts.
Conclusion. En dépit du traitement par AZT, le pronostic des formes symptomatiques de l'infection par le VIH reste très sombre.

W.B.P.346 EFFECTS OF ZIDOVUDINE DIFFERENT DOSE REGIMENS ON CLINICAL, IMMUNOLOGICAL AND VIROLOGICAL INDICES OF ARC PATIENTS FOLLOWED FOR ONE YEAR.

Cuneo-Crovari Piera *, Cassola G. **, Crovari P. *, Guida B. **, Icardi G.C. * and Piersantelli N. **
* Inst Hyg Prev Med, Univ of Genoa, Italy ** Dpt Infect Dis, Galliera Hosp, Genoa, Italy

Objective The aim of this study was to assess the progression of clinical symptoms and laboratory indices in HIV infected patients (intravenous drug users = IVDU) who received Zidovudine for 12 months at least in different dose regimens with or without Acyclovir in comparison with untreated subjects
Methods The trial included 60 IVDU (mean age 27.1 years) belonging to groups III and IV (AIDS excluded) of the CDC classification system. For all the subjects the number of peripheral blood CD4 lymphocytes was more than 150/cmm. The IVDU were allocated at random in groups of 20 subjects each, to one of the 3 following strategies: group A, AZT 200 mg/4 h; group B, 200 mg/6 h; group C, AZT 200 mg + Acyclovir 300 mg/6 h. Other 17 IVDU- ARC patients (ma = 26,7 y) who refused any antiviral therapy were considered as control (group D). During the follow-up, clinical and laboratory data were regulary collected (including CD4 cell number, virus isolation, serum HIV-Ag and anti-p24 titres, B2 microglobulin and Neopterin serum levels
Results During the trial 4 subjects dropped out the study (2 in group A, 1 in group C and 1 in group D) and no patient died. Among the treated subjects only 1 in group B (5%) developed AIDS in comparison with 3/16 (18.7%) in control group D. CD4 number significantly increased in treated subjects if compared with control group. The mean number of CD4/cmm in groups A and B changed from 221 and 196 at beginning of the study to 330 ($p=0.04$) and 337 ($p = 0.03$) respectively at month 12 of the follow-up; similarly, CD4 increased in group C (m0 = 303; m12 = 383; $p=0.02$). A decrease was observed, on the contrary, in the control group: m0 = 323; m12 = 244. Initially, 21 patients were HIV-Ag positive (6 in group A, 7 in group B, 5 in group C and 3 in group D). The appearance of HIV-Ag was not observed in anyone of the treated subjects, while it occurred in 2 untreated patients. A statistically significant decrease of HIV-Ag geometric mean titre was observed in the 3 groups of treated patients while it increased in group D. Anti-p24 titre was initially similar in all the 4 groups examined even if lower than in asymptomatic subjects (CDC II). This titre was constantly low in treated subjects while progressively decreased in untreated patients even if not significantly. The frequency of HIV isolation from peripherial blood lymphocytes was similar in treated and untreated patients. No significant change in B2M and Neopterin serum level was observed in the 4 groups. During the study no severe side-effect was observed and, consequently, no adjustment of the therapy was necessary. Nevertheless, a significant increase of MCV ($p<0.0001$) was noted in groups A, B and C; this often is an early sign of AZT toxicity.
Conclusions After 1 year AZT treatment of 60 ARC patients, no disease progression was observed (except 1 case) even in the groups who received drug every 6 h (instead of 4 h). Immunological and virological indices too, showed that HIV infection progressed slower in treated patients in comparison with untreated subjects.

W.B.P.348 PROGRESSION OF HIV INFECTED HEMOPHILIAS UNDER AZT TREATMENT ONE YEAR FOLLOW UP STUDY.

Mandalaki,Titika *;Karafoulidou, A.*;Gialeraki, A.*;Economidou,J.**;Makris,P.***;Potamianou,A.**;Psarra, K.**; Karabinis,A.*. *Laikon Hosp. Athens,Greece, **Evangelismos Hosp. Athens, Greece, ***AHEPA Hosp. Salonica, Greece.

Objective. To evaluate the tolerance, safety and effectiveness of zidovudine (AZT) treatment according to the clinical stage (Walter-Reed system) at the beginning of the treatment.
Methods. 15 HIV(+) Hemophiliacs aged 17-62 years,classified to WR 3,4 (n=11)(group A) and WR5(n=4)(group B) were under AZT(1 gr/day) for 6 to 15 months and evaluated clinically and laboratory monthly.
Results and Conclusions. All patients showed clinical and laboratory improvement during the follow-up months 1-3. 2 out of 11(gr. A) and 3 out of(gr.B) patients developed opportunistic infections at 6-12 months. Laboratory findings (see table). During the follow-up 2 out of 11(gr. A) and 2 out of 4 (gr. B) showed rising titers of HIV-Ag after the initial decrease.

Time (months)		0	1	3	6	9	12
Group A:	T4 (/mm3)	129	207	220	266	282	211
	Hct(%)	41	37	37	37	38	37
	WBC	4.200	3.800	2.300	3.000	3.300	3.500
Group B:	T4 (/mm3)	45	175	89	48	70	31
	Hct(%)	33	33	31	27	27	29
	WBC	3.400	3.500	2.300	2.400	1.700	1.900

These data suggest an early initiation of AZT treatment.

W.B.P.349 ZIDOVUDINE(AZT) IN HIV POSITIVE HAEMOPHILIACS

Lim, Seng Gee, Lee, CA, Hales, M, Giangrande P and Kernoff, PBA
Haemophilia Centre and Haemostasis Unit, Academic Department of Haematology, Royal Free Hospital, London, United Kingdom

Objective. To review the effect of zidovudine in HIV positive haemophiliacs

Methods: A retrospective analysis of 21 patients treated with zidovudine at the Haemophilia Centre of the Royal Free Hospital was performed. 14 were CDC IV, 1 was CDC III with thrombocytopenia, 4 had oral candidiasis, and 2 were CDC II but elected to purchase zidovudine privately. Median age was 33yrs(range 21-69) and they had been known to be HIV Ab positive for 42 -107 months (median 73 months) They received zidovudine for 1 - 55 weeks (median 20 weeks)

Results. 9 patients tolerated full dose zidovudine(1000 mg/d) without a change in dosage or side-effects. 12 patients required dose modification or cessation of medication due to anemia requiring transfusion(3), granulocytopenia(5), pancytopenia requiring transfusion(1), vomiting(1), poor compliance(1) and conversion to alternative medicine(1). Other side-effects were anorexia, headaches and fatigue. Opportunist infections that occured whilst on zidovudine were oral candidiasis(2), a possible relapse of PCP(1), Salmonella typhimurium septicaemia(1), cryptosporidiosis(1) and E. Coli sepsis from a UTI(1). 3 patients improved their T4 counts, 6 deteriorated, and 11 remained the same - some of these had a non-sustained rise in their T4 counts. 4 of 5 thrombocytopenic patients responded to zidovudine. 5 of 8, P24 Ag positive patients became negative, 2 remained positive and 1 has only had therapy for 1 week.

Conclusion. zidovudine is an effective treatment for symptomatic HIV infection in haemophiliacs, particularly for thrombocytopenia. However, there were significant side-effects anemia in 3/21(14.3%),granulocytopenia in 5/21(23.8%), and pancytopenia in 1/21(4.7%)

W.B.P.350 ZIDOVUDINE THERAPY IN HOMOSEXUAL/BISEXUAL PATIENTS WITH AIDS-RELATED COMPLEX (ARC) IN AUSTRALIA.

Swanson, Cheryl E; Cooper, DA.
NHMRC Special Unit in AIDS Epidemiology and Clinical Research, University of New South Wales, Sydney, NSW, Australia.

Objectives: To monitor the efficacy, toxicity and safety of zidovudine (ZDV) therapy in patients with AIDS-related complex (ARC) in a multi-centre clinical trial in Australia. Methods: Patients with ARC have been enrolled in the study since June, 1987. By June 1988, 301 homosexual/bisexual males had been enrolled, 95% of whom were still alive by 30 November, 1988. Using time to development of an AIDS-defining condition (TTAIDS) as a measure of the efficacy of ZDV, Kaplan-Meier survival curves were prepared for baseline clinical and laboratory values for these patients (Hb, WCC, CD4, age, time from diagnosis (Dx) to ZDV therapy, Karnofsky performance status (PS), and compared using the log rank test. A multivariate analysis of these same variables was performed using Cox regression analysis. Safety and toxicity were evaluated in terms of mean dose level of ZDV tolerated and need for transfusions during therapy. Results: Sixty-nine of the patients (23%) had developed AIDS conditions. Significant differences (< 0.05) in survival curves for TTAIDS were found for CD4 counts < 50 x 10^9, Hb < 12g/dl, Dx to ZDV time > 12/52 and PS <80. CD4 counts < 50 x 10^9 was the only baseline variable independently associated with poorer TTAIDS in this analysis. The mean dose of ZDV was 1.0g. Sixty-five patients (21%) required transfusions during therapy, of whom 27 were transfused only once.

Conclusion: ZDV appears to be well-tolerated in this group of ARC patients and baseline CD4 counts is independently associated with TTAIDS.

W.B.P.351 CESSATION OF ZIDOVUDINE (AZT) THERAPY LEADS TO INCREASED FREQUENCY OF VIRAL ISOLATION.

Wainberg, Mark A.; Fanning, M.; Gill, J.; Gelmon, K.; Montaner, J.S.G.; O'Shaughnessy, M.; Tsoukas, C.; and Ruedy, J.
Jewish General Hospital, Montreal, Quebec, Canada, and the Canadian Multicentre Study.

Objective: To carry out a dose-finding-toxicity study on 72 HIV-infected adults (CDC stages II and III) and to assess viral burden in such individuals.

Methods: HIV-1 was isolated from the circulating mononuclear cells of each subject at regular intervals throughout the study. Subjects received 600 mg drug per day for 18 weeks, 900 mg for 9 weeks, and 1200 mg for an additional 9 weeks. After 36 weeks, drug was withheld for 6 weeks and restarted at 42 weeks at 1200 mg/day.

Results: HIV was isolated from patients about 40% of the time both prior to treatment and at the end of 36 weeks, with average time to culture positivity of 19 days. At the end of the wash-out and following re-initiation of therapy, HIV was isolated in 75% of cases, with time to positivity of 12 days. These data correlate with the results on circulating p24 levels in these patients, and suggest that a 6-week drug wash-out period may result in increased viral burden.

Conclusion: Shorter wash-out periods should be used, when appropriate, to overcome the toxic effects of this drug.

W.B.P.352 IMPROVEMENT OF SURVIVAL IN AIDS PATIENTS WITH ZIDOVUDINE THERAPY.

Arici, Claudio; Rizzi M.; Pinazzi, MO. and Minola, E..
Department of Infectious Diseases, Ospedali Riuniti, Bergamo, Italia.

Objective. To compare survival after AIDS diagnosis, in patients admitted to our department before and after the introduction of zidovudine therapy.

Methods. We evaluated survival after the diagnosis of AIDS (Kaplan-Meier method) during 1985-1986-1987 (before zidovudine became available at our department) and in 1988 (when zidovudine was available for routine therapeutic use). Zidovudine was administered according to the Italian National AZT Programme (200 mg every four hours).

Results. Out of 100 patients, 93 were evaluable (minimal follow-up of 2 months); most of them (89%) were IVDA. 49 patients, observed in 1985-1987, did not undergo zidovudine therapy, regardless of their clinical condition. 43 patients, observed in 1988, were treated with zidovudine if responding to the inclusion criteria of the Italian National AZT Programme.

SURVIVAL FROM AIDS DIAGNOSIS % (Kaplan-Meier method)

month	3	6	12
1985-1987 ("pre-AZT era")	61.4	38.6	27.3
1988 ("AZT era")	76.4	69.4	59.5

Conclusions. Earlier diagnosis of AIDS and improvement in treating opportunistic infections, probably contributed to the observed increase of survival rates. Nevertheless, our results seem to confirm the favourable effect of zidovudine treatment on the survival of AIDS patients, also in IVDA, for which a poor compliance to long term therapies is to be expected.

W.B.P.353 EFFICACY OF AZT IN A MUNICIPAL HOSPITAL CLINIC

Cohn, Jonathan; McMeeking, A; Schlamm H; Vogler M; Allen S; Holzman, R. New York University-Bellevue Hospital, New York, New York, U.S.A.

Objective. To evaluate survival of AIDS and ARC patients treated with zidovudine (AZT) at a municipal hospital clinic.

Methods. Patients (pts) eligible for AZT under the Treatment IND or the FDA's licensed indications were treated in a specially designated clinic at Bellevue Hospital. Records of patients with at least one follow-up visit between Dec 86 and Nov 88 were reviewed using a standardized data form.

Results. 245 pts fulfilled the criteria for analysis: 220 males, 25 females; 141 whites, 61 hispanics, 39 blacks and 4 others; 146 homo/bisexual men, 82 with history of IV drug abuse; 82 pts had ARC and 163 AIDS. Median age was 37. Median survival (ms) of the entire group by the product limit method was 529 days (range 6-721) from the time of starting AZT. There was no difference in survival by sex. ARC pts lived longer than AIDS pts (ms 553 v 480, p=.01). Pts with 1 opportunistic infection (OI) prior to AZT lived longer than those with more than 1 OI (ms 501 v 357, p<.02). Initial absolute lymphocyte count above 1188/cu mm, absolute CD4+ lymphocyte count above 110, and albumin over 4 g/dl were associated with significantly longer survival by univariate analysis. Pts who started AZT within 90 days of their first AIDS diagnosis lived significantly longer. Those who tolerated an average AZT dose above 5.6 grams/week survived longer than pts treated with lower doses (p<.003). Adverse reactions included anemia in 80 pts, leukopenia in 51, nausea in 28, thrombocytopenia in 25, hepatitis and myositis in 16 each, and other toxicity in 36.

Conclusion. Patients from a municipal hospital population treated with AZT survived at least as long as those reported in other trials.

W.B.P.354 THE EFFECT OF ZIDOVUDINE (AZT) ON SURVIVAL OF AIDS PATIENTS IN SAN FRANCISCO

Lemp, George F.; Payne, S.F.; Neal, D.P.; Rutherford, G.W.
San Francisco Department of Public Health, San Francisco, CA, U.S.A.

Objective. To evaluate the effect of zidovudine (AZT) on survival trends for AIDS patients diagnosed in San Francisco (SF) in 1986 and 1987.

Methods. Information on antiviral therapy was available for 668 (25%) of 2,723 AIDS patients diagnosed in 1986 or 1987 in SF. We evaluated survival for 172 AIDS patients treated with AZT at some point during the course of their illness compared with survival for 485 AIDS patients who were not on any antiviral therapy at time of diagnosis (and, if known, subsequent to diagnosis). Eleven patients using other antivirals were excluded. Median survival was calculated using the Kaplan-Meier product-limit method.

Results. The median survival for patients on AZT (21.3 months) was significantly longer than for patients not on any antiviral therapy (13.9 months) (p<0.001). Improved survival for patients on AZT was found for both patients with (21.6 vs. 14.9 months) and without (21.3 vs. 13.1 months) Pneumocystis carinii pneumonia within 3 months of diagnosis (p<.001). Improved survival for patients on AZT was found for all subgroups of patients when stratified by initial diagnosis, year and hospital of diagnosis, age, race/ethnicity, or risk group, suggesting that the improved survival for patients on AZT was probably not due to biases inherent in the sample.

Conclusion. Survival for patients on AZT was significantly longer than that for patients not on antiviral therapy in a sample of AIDS patients in SF.

W.B.P.355 ZIDOVUDINE (AZT). PREVENTIVE TREATMENT OF AIDS IN HIV SEROPOSITIVE PATIENTS ?

Tourani, Jean-Marc ; Stern, M. ; Volstein, M. ; Lowenstein, W. ; Andrieu, J.M. for the Laennec HIV Study Group - Laennec Hospital, 42 rue de Sèvres - 75340 PARIS CEDEX 07 - FRANCE)

To assess the efficacy of Zidovudine (AZT) in the prevention of AIDS we conducted, in September 1987, an open study in 75 non AIDS/HIV seropositive patients with a low T4 cell count (CD4 < 300/ul). 39 patients (groupe I) received AZT (20 mg/kg/d) and 36 patients (groupe II) received no treatment. At entry, group I and II patients were comparable in terms of age, sex and risk factors.

	Asymptomatic	PGL	ARC	P24 Ag	P24 Ag pg/ml mean	CD4 cell/ul mean
Group I (n=39)	12	11	16	15	387	180
Group II (n=36)	7	17	12	14	285	185

During the first 12 months of follow-up, AIDS occurred in 10 group II patients (7 opportunistic infections (OI) ; 3 Kaposi's sarcoma (KS)) and in 2 group I patients (2 OI). The 12-month actuarial rate of AIDS occurrence was 12% and 36% in groups I and II respectively (P=0.089) AZT related side effects occurred in 33% of patients. Major side effects included 1 case of hepatic toxicity (temporary discontinuation of AZT) 5 cases of hematological complications (blood transfusions were necessary in 4 of these patients).
In conclusion, at 12 months follow-up, AZT seems to prevent the occurrence of AIDS in HIV patients with low CD4 cell counts. However, a study enrolling a larger number of subjects is needed to confirm such a trend and a longer follow up period might eliminate the fact that the drug only postpones the occurrence of AIDS.

W.B.P.357 DISEASE STATUS AND HIV ISOLATE REPLICATION IN 31 HAEMOPHILIACS INCLUDING 11 AZT TREATED PATIENTS

Elio Boeri*; Mori,P.G.*; Franchini, E.**; Lanza, T.**; Ferrari,G.***; Varnier O.E.***.
*Dept. Haematology & Oncology, **Blood Bank, G. Gaslini Institute, ***Lab. Human Retrovirology, Genova, Italy.

Objective. Correlation of disease status to the replicative properties of HIV isolates in 31 infected haemophiliacs including 11 AZT treated patients.
Methods: 31 haemophiliacs contracted HIV infection between 1980 and 1984; at present, 10 are classified CDC group II and 21 group III. Clinical, immunological and virological analysis have been routinely done since 1984.
Results: Although no overt disease was observed, a low percentage (<30%) and number (<400) of T4 cells occured in most of them. HIV was isolated from 27 haemophiliacs and isolates showed high, moderate and low replicative properties. Eight highly replicating HIVs were isolated from patients, who showed signs of disease progression (trombocytopenia, T4 cell loss or antigenemia). On the contrary 7 subjects, with relatively good clinical status and immunological parameters, released slow replicating viruses and no detectable p24 in the serum. Independently from the type of HIV isolate, AZT therapy slightly improved the clinical and immunological conditions.
Conclusions: Antiviral treatment should be started immediately after virus isolation regardless the clinical status.

W.B.P.359 AN OPEN TRIAL OF ZIDOVUDINE(AZT) IN 17 ZAIRIAN PATIENTS WITH AIDS.

Kapita, Bila*; Milangu, M.*; Nyst, M.*/**; Musongela, K.*; Chalhoub, E.***; Ryder, R.**/****; *Mama Yemo Hospital, Zaire; **Projet SIDA, Kinshasa; ***CDC, Atlanta, GA.U.S.A.

Objective. To observe the clinical efficacy of AZT in African patients with AIDS hospitalized at Mama Yemo Hospital (MYH), Kinshasa, Zaire.
Methods. Between March and December, 1988, at MYH, 17 patients with AIDS were treated with AZT in a dosage of either 200 mg/4 hours or 600 mg/12 hours. To have parameters which could be used to quantify drug efficacy, patients fulfulling the WHO clinical criteria for AIDS and presenting with a history of persistent diarrhea and/or pruritic dermatitis and/or Kaposi's sarcoma were included in the trial. Patients were followed weekly. Clinical and hematological parameters were monitored for evidence of AZT-induced toxicity.
Results. Ten women and seven men (age range 27-46 years) were included in the trial. All 17 patients experienced weight gain during the first several weeks of treatment (average weight gain=6 kgs; average time between start of treatment and maximum weight gain=4 months). The 17 patients have now been followed for a total of 321 weeks. Anemia and/or leukopenia requiring temporary drug cessation occurred in 5(29%) of the 17 patients for a total of 29 weeks(9% of the total length of time of enrollment of patients in the trial). Total treatment time was 292 weeks. During the trial patients have collectively experienced fever for 6% of the total observation period. They have had 30 episodes of diarrhea (average duration=6 days) for an incidence of 102 episodes/100 years of patient observation. There were 18 episodes of dermatitis giving an incidence of 62/100 years. The two cases of Kaposi's sarcoma which were present at the start of therapy both progressed while on treatment. Herpetic infection (35% of patients), oral candida (18%), deep skin abscess (24%) developed during therapy.
Conclusion. AZT induced a transient amelioration in the overall clinical status. Nevertheless, while on therapy many patients continued to experience diarrhea, dermatitis and opportunistic infections.

W.B.P.356 OPEN TRIAL OF THE LONG-TERM SAFETY OF ZIDOVUDINE - INTERIM ANALYSIS

Houle, Linda*; Peake, Joanne*; Fletcher, Malcolm*; and the Canadian Zidovudine Collaborative Group* Burroughs Wellcome Inc., Kirkland, Québec, CANADA

Objective.To present an interim safety analysis of this ongoing Canadian "Open Trial of the Long-Term Safety of Zidovudine."
Methods. There are 9 provincial study centres in Canada. Follow up is required on each patient entered every 2 weeks for the first 2 months and then once every month afterwards.
Results.On January 6, 1989 the study, which began in November 1986, had enrolled 2 482 patients. At baseline they were grouped according to the following CDC classifications: 850-4C1(post PCP);98-4C1(post other OI's);718-4C2;272-4A; 480-3(PGL). Sixty-four patients were transferred into this study from another Zidovudine study which ended in 1988. There are 2 131 (85%) patients taking Zidovudine. Approximately 75-80% of them are not on the full daily dose (1200mg). There are 212 patients deceased and 139 patients who are permanently discontinued. The most frequent adverse reaction reported requiring treatment was anemia. The number of patients transfused per province varies and there appears to be a declining trend in incidence of transfusions.
Conclusion.This Canadian Zidovudine study will generate much useful data on the safety and use patterns of patients taking Zidovudine. An effort must be made to improve the overall rate of follow-up.

W.B.P.358 MAJOR OPPORTUNISTIC INFECTIONS IN AIDS PATIENTS AFTER EIGHT TO ONE HUNDRED FIFTY WEEKS OF ZIDOVUDINE THERAPY

Causey, Dennis M., Leedom, J. M., and Melancon, H.
University of Southern California, Los Angeles, CA USA

Objective. To describe the incidence and types and outcomes of AIDS-defining opportunistic infections (OI's) in patients treated with ZDV for 8-150 weeks.
Methods. Twenty-two patients with previous Pneumocystis Carinii pneumonia (PCP) were enrolled. Nineteen of the 22 completed more than 8 weeks of ZDV therapy. Eleven received ZDV 250 mg every four hours for 10-12 weeks and then 200 mg every four hours thereafter. The other 8 patients received ZDV 200 mg every 4 hours. ZDV was reduced to 100 mg every 4 hours for granulocytopenia (PMN's <750) or discontinued (PMN's <500). ZDV was resumed when the toxicity was reversed.
Results. Fifteen of the 19 patients (79%) developed recurrences of PCP between weeks 10 and 130. Most of these recurrences were mild. However, fatal complications developed in 3 of the recurrent PCP patients. Three patients developed cryptococcal meningitis between weeks 12-60. Two were ultimately fatal. Four developed cytomegalovirus (CMV) retinitis, another CMV viremia with wasting syndrome, and another CMV colitis. Four developed disseminated Mycobacterium Avium. Two developed central nervous system toxoplasmosis. One developed cryptosporidial diarrhea. Two developed chronic peri-rectal herpes simplex. Adverse reactions to ZDV were minimal except for bone marrow toxicity. Dosage interruptions were required in all patients but seldom lasted over 7 days.
Conclusion. Eighteen out of 19 patients (95%) developed major OI's during long-term ZDV therapy. Ten of these OI's were fatal. While ZDV therapy may decrease the incidence of OI's initially, such OI's continue to occur and can result in fatalit y. However, Six of 19 patients have demonstrated long-term (> 3 years) survival. Patients tolerate well long-term ZDV therapy with occasional dosage modifications if significant granulocytopenia occurs.

W.B.P.360 ZIDOVUDINE DELAYS DEVELOPMENT OF AIDS FOR PATIENTS WITH 4C-2, 3 and 4A HIV DISEASE

Rachlis, Anita*; Bonner, M.*;Fletcher, M.**;Houle, L.**
*Sunnybrook Medical Centre and the University of Toronto, Toronto, Ontario, Canada, **Burroughs Wellcome Inc., Kirkland, Quebec, Canada.

Objective: To establish drug use patterns and the rate of progression to AIDS in a group of 4C-2, 3 and 4A patients treated with zidovudine.
Method: A group of patients was followed for at least 6 months in the Ontario Canada open zidovudine treatment study: 136 4C-2 patients, 67 category 3 patients and 23 patients in category 4A.
Results: At a mean follow-up of 38.5 weeks, 75% of the sample remained on zidovudine at full or reduced dose. On average, of each 100 days, patients received full dosage for 30 days, a reduced dose for 40 days and had therapy suspended for 30 days. The majority of dose reductions and discontinuations were due to drug-related hematologic toxicity. Eight patients experienced 4C-1 opportunistic infections (OIs): 6 developed PCP and 2 had CMV disease. One had died at follow-up. Patients with previous 4C-2 OIs had AIDS diagnosed at a mean of 249 days after the original minor OI. For the rest of the 4C-2 patients the mean number of days without major infection was 512. The following did not appear to be predictive of progression to AIDS: anemia, thrombocytopenia, neutropenia or a severely depressed CD4 count at entry or the length of time at a reduced dose or time off zidovudine.
Conclusion: Progression to AIDS for 3.5% of the sample duplicates results of the initial placebo-controlled trial and is lower than rates obtained from historical controls. Of note is the fact that patients were at reduced dose or off the drug for 70% of the follow-up period. Further study is warranted to establish if a lower, less toxic dosage is, in fact, an efficacious one.

W.B.P.361 TREATMENT WITH RETROVIR IN DIFFERENT STAGES OF THE HIV INFECTION

MAIO G., IZZO C.M., MANZILLO E., BUONOCORE S., MANZILLO G..
"D. COTUGNO HOSPITAL"-USL 41- NAPOLI - ITALY.

54 HIV-Ab positive patients(6of II group,13 of III group,35 of IV group of CDC classification)received AZT in doses of 1200mg/die for 6-20 months:48 of these patients(89%)were drug abusers(d.a.); 16 of then(33%)resulted dropped out(d.o.)during the first three months(1 of II group,6 of III group and 9 of IV group):there weren't d.o. among those who aren't d.a..47% of the followed since the beginning(time 0)showed n° of CD4 > 400.There were serious side effects in 26% of the patients,which resulted in interruptions of the treatment.There were none in those from II and III groups. In spite of the treatment,40% of the patients of the II group and 29 of those of III group showed development in more advanced stages of the syndrome,without correlation with the number of CD4 at time 0.Among the followed 26 patients of IV group,73% showed stationary conditions during the time and 19% died(we have registered deaths in 54% of other 39 patients of IV group,who didn't receive AZT).Among 32 d.a. followed,we observed a development of the syndrome in more advanced stages in 60% of those who went on taking drugs and only 30% of those who had given up this habit (P > 0.01).Of the six patients not d.a.,66% have remained stationary and 1(16.6%)died.

W.B.P.362 EFFICACY AND TOLLERANCE OF ZIDOVUDINE IN PATIENTS WITH ASYMPTOMATIC HIV INFECTION OR WITH PGL.

A.Chirianni, F.Tullio Cataldo, S.Noce, G.Bonadies, L.Picciotto, M.Piazza. Clinic of Infectious Diseases University Naples-Italy.

Objective. Evaluation of the effects and tolerance of Zidovudine (ZDV) in HIV seropositive patients..
Methods. 10 asymptomatic patients (CDC group II) and 10 with PGL (CDC group III) all with initial T4 counts ranging between 150 and 300/mmc were given ZDV 7 mg/kg for 4 times a day for the first month and 3.5 mg/Kg for 4 times a day for an additional seven months.
Results. No patients showed OO.II. and/or tumor. Nausea and headache were not frequently observed. All subjects developed mild decrease in hemoglobin (mean Hgb=14.38 gm/dl at entry and 14.04 at month 8) and in PMN cell counts (mean PMN=2532/mmc at entry and 2407 at month 8). Anormal CPK values were observed in 3 subjects during treatment. In 2 patients GPT values 3 times the normal value was observed in the first month followed by normalisation. HIV Ag was detected in serum of 3 patients at entry and 2 became persistently HIV Ag negative during the treatment. Mean T4 count was 198/mmc at entry and 179/mmc after 8 months.
Conclusion. ZDV at the dose indicated was fairly well tolerated during first 8 months of therapy. The slight T4 cells decrease is an expression of the efficacy of the treatment. Further study will be needed to determine the long-term effect of therapy.

W.B.P.363 LONG TERM ASSESSMENT OF TOXICITY AND CLINICAL OUTCOME IN TREATMENT OF HIV INFECTION WITH ZIDOVUDINE

Dyner, Toby; Lang, W.; Geaga, J.; Bender, J.
AIDS Clinical Research Project,Children's Hospital of San Francisco,California, U.S.A.

Objective. To evaluate the toxicity and assess the long term clinical outcome of Zidovudine therapy in HIV infected individuals diagnosed with AIDS or who have been symptomatic with less than 200 CD4 cells.
Methods. A prospective, open-ended uncontrolled study of Zidovudine therapy began in December of 1986. By the end of December 1988, we enrolled and treated 27 patients with AIDS and 19 patients with HIV related symptoms and less than 200 CD4 cells (CDC stage IVa disease).
Results. Mean follow-up of 69 weeks is available for 26 patients with AIDS and 56 weeks for 12 of 19 patients with CDC stage IVa disease. Neutropenia with less than 750 cells per cubic millimeter occurred in 37% of patients (11 with AIDS; 3 with stage IVa disease). Transfusions were required in 24% of patients (8 with AIDS; 1 with stage IVa disease). Recurrent opportunistic infections including PCP, CMV retinitis, CMV colitis, and disseminated MAI were noted in 50% of the AIDS patients. 3 of 12(25%) evaluable CDC stage IVa patients have progressed to AIDS. 56% of patients diagnosed with AIDS at start of therapy have died while 27% remain on drug. 8% of evaluable patients with symptoms and less than 200 CD4 cells at start of therapy have died while 75% remain on drug.
Conclusion. Our experience with Zidovudine therapy in HIV infection is similar to that of other investigators. Zidovudine prolongs survival in this population by decreasing morbidity from recurrent OIs. The major limiting factor in prolonged use remains the hematologic toxicities.

W.B.P.364 ZIDOVUDINE TREATMENT IN 100 CONSECUTIVE PATIENTS WITH AIDS OR AIDS RELATED COMPLEX.

Roudot F, Hargous ML, Sobel Alain , Cassinat B, Rekacewicz I,Lyonnet F et al. Hôpital Henri Mondor, 94010 Créteil, France.

Objective. To analyse Zidovudine treatment in severe HIV infection in terms of survival, toxicity and dose maintenance.
Methods. 100 consecutive patients with AIDS and ARC received Zidovudine at a starting dose of 600-1200 mg per day. The drug was always given orally every 6 hours. The patients comprised 55 AIDS patients (30 O.I., 16 isolated K.S., 7 with boths, 2 with neurologic disorders) and 45 ARC patients. The mean duration of follow-up under treatment was 8,2 mo (0,2-18). 15% of the patients were IVDA.
Results. At 6 mo after beginning AZT only 35% of the patients (63% of ARC) received the initial dose. The causes of regimen alteration included hematological toxicity (41%), intercurrent events (10%), combination therapies.9 ARC patients progressed to AIDS under treatment. 42 O.I. were observed in 24 patients. The 12 mo survival rates from the beginning of AZT treatment were 70.4% in ARC patients, 69.4% in AIDS with I.O., 72.4% in KS patients, 42.9% in KS + O.I. patients. The 18 mo rates were 70.4 % in ARC but only 55.5 % in AIDS.
Conclusion. Zidovudine provided a better quality of survival which might be slightly prolonged. But starting doses are reduced in 2/3 of the patients within 6 mo because of toxicity. Moreover 20% of ARC patients moved to AIDS while treated although the initial dose had been maintained in most.

W.B.P.365 CORRELATION BETWEEN P24 ANTIGENAEMIA AND CD4+/NEOPTERIN RATIO IN AZT-TREATED PATIENTS

Crocchiolo Paolo,Lizioli A.,Panzeri MP.,Filippi C., Arcidiacono I.,Nardella ML. - Ospedale Maggiore - 20075 LODI (Italy)

Objective: to verify whether CD4+/neopterin ratio (R) correlates with clinical course and p24 Antigenaemia (p24Ag) in AZT-treated patients infected with HIV.
Methods: 14 HIV-positive pts (10 males,4 females,mean age 24.3,range 20-32 years; 6 p24Ag pos.,8 p24Ag neg. at enrolment) were daily administered 10 mg/Kg AZT per OS for 1 year. Every 3 months they were clinically evaluated (according to CDC criteria) and tested for serum Neopterin levels (SNL), CD4+ cell counts and p24Ag; R was also 3 monthly calculated for each patient.
Results: Clinical condition did not worsen in any of the 14 pts during the 12 months' treatment; in fact clinical improvement was noted in 4. According to "between-variance" analysis,however,no statistically significant immunological improvement (CD4 and R increase,SNL decrease) was observed in our pts,regardless of their initial p24Ag status.
Conclusion: in our experience,R proved to be the most sensitive index of immunological response to treatment correlating, to a certain extent,with p24Ag. In fact,it may be proposed as the only immunological index (replacing p24ag) in the monitoring of AZT-treated patients.

W.B.P.366 Suivi clinique et biologique de 106 malades traités par ZIDOVUDINE sur une période de 12 à 18 mois.

BOILLOT, Corinne ; PESCE, A ; QUARANTA,J.F.; VINTI, H. ; TAILLAN, B. ; CASSUTO, J.P. ;
C.H.R.U. de NICE, FRANCE. Ligue Régionale Française de Lutte contre le SIDA.

Objectif : évalué à long terme, la survie, l'apparition des infections opportunistes et la modification des lymphocytes T4 chez 106 malades du groupe 3 et 4 traités par ZIDOVUDINE.
Méthode : suivi clinique et biologique mensuel des 106 malades sur une période de 12 à 18 mois.
Résultat : - pourcentage de survie : stade 3 et 4 confondus.

6 mois	12 mois	18 mois
88 %	78 %	65 %

- à 6 mois:78 % sous placébo (Wellcome Mai 87)

- apparition ou récidive d'infections opportunistes :

	6 mois	12 mois	18 mois
Stade 4C1	33 %	44 %	61 %
Stade 3+4	18 %	32 %	48 %

- à 6 mois, 48 % sous placébo (Wellcome mai 87)

- Pourcentage de patients en fonction des taux de T4 et du temps :

	1e	2e	3e	4e	5e	6e	7e	8e
↗>20%	64%	52%	39%	24%	21%	38%	21%	8%
Stable	20%	18%	17%	30%	41%	19%	25%	32%
↘>20%	16%	30%	44%	46%	38%	43%	54%	60%

Conclusion : malgré une baisse progressive des lymphocytes T4 et d'un pourcentage important d'apparition ou de récidive d'infections opportunistes la survie sous ZIDOVUDINE est appréciable (65 % à 18 mois).

W.B.P.367 AZT THERAPY IN INTRAVENOUS DRUG USERS (IVDU'S) AND THEIR SEXUAL PARTNERS

Spears,Alice; Landesman,S; Shafer,R; Chirgwin,K; Dehovitz,J.
Kings County Hospital Center and SUNY - Health Science Center at Brooklyn, U.S.A.

Objective: Describe the experience of our clinic in administering AZT to IVDU's and to sexual partners of IVDU's.
Methods: 59 consecutive pts who were IVDU's or who were sexual partners of an IVDU were begun on AZT between 1/87 - 3/88.
Results: 35 were male IVDU's (mean age:37.5, range:23-54). 24 were female (mean age:33.2, range:24-39); 10 females were IVDU's and 14 were sexual partners of an IVDU. 46 had AIDS (pneumocystis pneumonia-39, other opportunistic infection-7); 13 had ARC with a mean T4 of 135 (range:60-292). 39/59(66%) pts were compliant with therapy for a mean of 10.9 months of follow-up (425 pt-months): 16 died after a mean of 10.5 months (range:5-19), 12 are alive after a mean of 15.8 months (range:10-24), 7 required discontinuation of AZT due to adverse reactions after a mean of 8.7 months (range:1-19), and 4 transferred to another facility after mean of 9.8 months (range:2-24). 20/59(34%) were lost to follow-up after mean of 5.7 months of therapy (range:1-15)(114 pt-months). 23 developed an opportunistic infection while on AZT. 16 required RBC transfusions. 22 required dose reductions due to anemia (11) or neutropenia (11).
Conclusions: Most pts in this cohort of IVDU's and sexual partners of IVDU's were compliant with AZT therapy as judged by their record of clinic attendance. Efficacy can not be assessed due to the lack of a control group. Adverse reactions to AZT were similar to those previously described in other groups of pts.

W.B.P.368 TREATMENT OF SYMPTOMLESS HIV SEROPOSITIVE SUBJECTS BY AZIDOTHYMIDINE (AZT). A CONTROL STUDY IN 56 PATIENTS.

Vittecoq,Daniel*, Lefrère, J.J.**, Lambin, P.**, Mettetal, J.F.*, Rouzioux, C.*, Courouce, A.M.**, Bach, J.F.*.
* Dpt of Immunology, Hôpital Necker ; ** I.N.T.S., Paris, France.

Objective. To determine the effect of AZT in symptomless HIV seropositive subjects.
Methods. Comparison of 2 cohorts of 28 asymptomatic subjects (CDC II ou III) matched according to CD4 cell count (+/- 20/mm^3) and p24 antigenemia (ag) (detectable or undetectable). A group of subjects was untreated while the other received AZT (300mg every 6 hours) + acyclovir (800mg/day) during one year. Clinical and biological (CD4 and CD8 cell count, p24 ag) evaluation was performed at 0, 6, 12 months.
Results. 26 treated subjects were evaluated ; 2 subjects were excluded due to drug induced anaemia. No significant modification of haemoglobin level and total leucocyte count occurred in the others. No modification of clinical staging was noticed in treated subjects while 3 untreated subjects became CDC IV ; p24 ag, initially undetectable in 11 subjects in both groups, remained undetectable in all treated subjects while it became detectable in 2 untreated subjects. A decrease of p24 ag level was noticed in treated subjects when p24 ag was initially detectable (respectively 210,78 and 80 pg/ml at 0,6,12 months; $p<0.001$). No modification of total lymphocyte count was noted in either groups. A CD4 cell count increase was noted in treated subjects (350,429 and 445/mm^3 at 0,6,12 months; $p<0.05$), contrasting with a decrease in those untreated (354,286 and 274/mm^3; $p<0.01$). A CD8 cell increase was also noted in treated subjects (701,927 and 999/mm^3; $p<0.01$).
Conclusion. AZT is of interest in symptomless HIV infection despite the risk of anaemia.Placebo controlled trials requiring long follow-up are warranted and ethically suitable only in subjects having CD4 cells >400/mm^3 and an undetectable p24 ag.

W.B.P.369 AN INTERMITTENT ZIDOVUDINE REGIMEN: TOXICITY AND EFFICACY

Rodsworth Neil, Cooper David A. NHMRC Special Unit in AIDS Epidemiology and Clinical Research. U NSW, Australia.

Objective. To assess the efficacy of an intermittent regimen of zidovudine.
Method. 21 men (6 with AIDS, 15 with ARC) who developed hematotoxicity on continuous zidovudine therapy despite dose reduction (1.2g → 0.75g/day) were followed on an intermittent regimen of AZT (4 weeks of 1 g per day, 4 weeks without drug). The effect of zidovudine on clinical response, transfusion requirements, blood counts, viraemia and CD4 cells was analyzed on continuous therapy (26.1 weeks) compared with intermittent therapy (23.4 weeks).

Results.	Pre AZT	Continuous AZT	Intermittent AZT
New OIs or KS	-	3 (2 subjects)	3 (2 subjects)
p24ag no +ve	10	10	9
pg/ml	377 ±136	112 ±38	272 ±20
CD4 cells x10^6/l	131 ±18	105 ±17	63 ±15
Transfusions patients	-	14	2
number (units)	-	36 (240)	4 (16)
Hb g/l	13.4 ±.31	7.9 ±.42	11.6 (11.2* 12.1†)
WCC 10^9/l	4.29 ±.34	2.53 ±.20	2.95 (2.81* 3.09†)
G'cytes 10^9/l	2.44 ±.23	1.30 ±.13	1.64 (1.61* 1.67†)

all values are mean ±SE. * on zidovudine. † off zidovudine.

Conclusion. Anaemia improved markedly on intermittent AZT and transfusion requirements were minimal. Despite more severe immunodeficiency and anaemia consistent with more advanced disease at the time of commencement of intermittent therapy, the occurrence of new opportunistic disorders was similar for both regimens. On the basis of these findings, studies of the efficacy of intermittent zidovudine as initial therapy should be undertaken.

W.B.P.370 LONG-TERM SAFETY AND EFFICACY OF ZIDOVUDINE IN LARGE COHORTS OF IV DRUG ABUSERS: 20 MONTH EXPERIENCE WITH 200 AYMPTOMATIC, 500 ARC AND 400 AIDS PATIENTS.

Vella, Stefano*; Menniti Ippolito, F.*; Agresti, M.G.* and The Italian Zidovudine Evaluation Group.
* National Institute of Health, Rome, Italy.

Objective. To evaluate the long term safety and efficacy of zidovudine (ZDV) when administered in I.V. drug abuser HIV-infected patients.
Methods. Data contained in the Italian National Registry of ZDV-treated patients have been analyzed. The Registry prospectively collected enrollment and quarterly follow-up forms of 1100 patients referring to 105 clinical centers involved in ZDV open therapy, which started in Italy in July 1987. Multivariate analysis has been performed in order to evaluate the effect of possible co-factors on therapeutic response and survival patterns, and on the occurence of adverse events in this particular population.
Results. Frequency of adverse effects appeared to be similar to frequency reported in other risk categories of patients, haematological adverse reactions beeing minimal in AIDS and ARC patients who initiate therapy with over 200 CD4/cells. ZDV also appeared to be very well tolerated in asymptomatic patients, with no unexpected adverse reactions. One-year overall survival of AIDS patients was 90.9%. The 18-month actuarial progression rate to ARC and AIDS has also been evaluated for the studied population.

W.B.P.371 USE OF ZIDOVUDINE (AZT) IN INJECTION DRUG USE (IDU) RELATED HIV INFECTION - CLINICAL OUTCOME

Cowan FM, Jones ME, Flegg PJ, MacCallum LR, Brettle RP, Gray JA, et al. Infectious Diseases Unit, City Hospital, Edinburgh, UNITED KINGDOM

Objective: To evaluate clinical outcome of AZT therapy with IDU-related HIV infection (IDUHIV) in view of increased AZT levels in opiate users.
Method: 322 HIV seropositives were assessed of which 253 (79%) were infected between 1983-85 by IDU. Of 51 AZT treated patients 37 are male (22 IDUHIV, 15 homosexuals [HO]) and 14 female (13 IDUHIV, 1 heterosexual). Outcome was assessed in terms of clinically significant opportunistic infections (OI), side effects (SE) attributable to AZT and survival since starting AZT.
Results: 22 patients started AZT when they developed AIDS (CDC 4C1/4B/4D). 13 were HO (mean duration of treatment [D]=48 weeks) and 10 were IDUHIV (D=36 weeks). SE requiring dose reduction developed in 5 (50%) IDUHIV and in 6 (46%) HO. Significant OI 6 weeks post start of AZT occurred in 3 (30%) IDUHIV and in 8 (62%) HO. Three (23%) HO with AIDS have died of their disease (mean time after starting AZT=56 weeks). Two HO started AZT when they had ARC (CDC 4C2/4A/4E) (D=43 weeks) compared with 19 IDUHIV (D=39 weeks). SE requiring dose reduction developed in 6(32%) IDUHIV and in 1(50%) HO. Significant OI developed in 3(16%) IDUHIV but in neither HO. As yet no ARC patients have progressed to AIDS. One (6%) IDUHIV has to date died from non HIV causes. Four IDUHIV were CDC status 3 (D=44 weeks). None of them developed SE or OI.
Conclusion: The frequency of serious events (OI and SE) is not greater or efficacy less in IDUHIV despite opiates/benzodiazepines having an effect on AZT pharmokinetics.

W.B.P.372 ZIDOVUDIN IN ARC AND AIDS PATIENTS: CLINICAL, IMMUNOLOGICAL AND VIROLOGICAL EFFICACY.

Höffken,Gert*,Petri,R.*,Deppermann,K.M.*,Ludwig,W.D.*,Mielke,M.**,Jarr,B.*** et al.
*Medical Clinic Klinikum Steglitz,**Institute of medical microbiology and *** clinical and experimental virology, 1000 Berlin 45,F.R.G.

Objective. To evaluate the clinical,immunological and virological efficacy of Zidovudin (AZT) in ARC and AIDS patients (pts).
Methods. Open, non-comparative prospective trial. Evaluation criteria (3-months interval): (1)clinical: incidence of AIDS-indicative diseases and disease progression,resp., (2)immunological: T-lymphocyte phenotyping with immunofluorescence by flowcytometry (CD4+,CD8+,CD8+Leu7+) and whole-blood lymphocyte proliferation assay with pokeweed mitogen and tetanus toxoid stimulation, (3)virological: HIV culture in primary blood lymphocytes and p24 antigen capture test (Dupont Co.).
Results. Until 1/1988 38 HIV seropositive (ELISA,WB) ARC and AIDS pts. (all male homosexuals, [illegible]) are treated with 1.0g/d AZT orally for a mean duration of 276±174 days, 16 pts >6 months.In 12 and 10 pts dose reduction and cessation because of drug toxicity (leukopenia,anemia,hemolysis) became necessary,resp..12/38 pts.(16/19 with AIDS) developed CDC-C1/D classified diseases, 5 pts died due to infectious complications. CD4+(CD8+ and CD8+Leu7+,resp.) lymphocytes decreased from 116±86 (902±431 and 438±234/µl,resp.) before therapy to 48±53 (376±333 and 179±104,resp.)after 6 months. No change in lymphocyte proliferation could be detected (PWM 4027±4313 vs.2886±4404,tetanus 1300±2304 vs.1737±3600, normal >60.000 and 8000cpm,resp.).HIV could be cultured in 13/20 (65%) before and in 11/16 (69%) after 6 months of therapy.

Conclusion. The efficacy of zidovudin in AIDS pts was limited. No improvement of immunological,functional and virological parameters could be seen. Only in ARC pts AZT demonstrated some clinical value.

W.B.P.373 COMPLIANCE WITH ZIDOVIDINE (AZT) THERAPY IN AN INNER-CITY HIV-INFECTED POPULATION.

Williams, Ivetta Y.*; Noel-Connor, J.* and El-Sadr, W.*.
*Harlem Hospital Center, New York, N.Y.U.S.A.

Compliance to AZT was retrospectively evaluated in HIV-infected outpatients. Eighty-two patients (pts) were prescribed AZT between 11/86-7/88. Thirty-five are alive and on treatment (Rx), 7 were refered elsewhere, 1 requested stopping AZT and 11 never started AZT. Twenty-eight pts were followed from start of Rx to their death. There were inadequate data on 4 pts. Charts of 24 of the latter group were reviewed. All 24 pts were black and 22 (92%) were men. The mean age was 40.4±9.4 yrs (range 25-63 yrs). Eighteen of the 24 (75%) were Intravenous Drug Users (IVDUS), 5 of 24 (20.8%) were homosexual men and 1 (4%) denied all risks. The primary diagnoses were esophageal candidiasis in 10 of 24 (41.6%), P. carinii pneumonia in 8 of 24 (33.3%), cryptococcal meningitis in 2 of 24 (8.3%) and 1 (4.1%) each of Kaposi's sarcoma, TB, salmonellosis and HIV positive. The pts were on AZT for a mean of 6.9±5.2 months (mths) before their death (range 1-18, median 9 mths). Four of 24 pts were excluded as they remained hospitalized. There were 222 scheduled appointments (Appt) for 20 pts and 42.3% were kept. The mean percentage (%) of appt. kept by pts was 24.2% (range 0-75%, median 35.5%). There was no statistically significant difference in compliance % between IVDUS versus homosexual men, those below and above 40 yrs, those living in and outside the hospital catchement. There was a significant association between compliance % and the duration of AZT Rx, 40.2% in those 9 months versus 28.5% in those 9 months. In conclusion, this study shows that acceptable though not ideal compliance was achieved in a subgroup of black predominantly IVDUS with HIV disease.

W.B.P.375 OUTPATIENT TRANSFUSION THERAPY FOR RETROVIR-ASSOCIATED ANEMIA

Weiss,Susan; Visser,E.; Rodgers,P.; McMeeking,A; Schlamm,H.
AIDS Program, Bellevue Hospital Center, New York, NY, USA.

Objective. To demonstrate the feasibility and safety of outpatient transfusion therapy for patients with Retrovir-associated anemia (RAA)
Methods. In a designated section of the general outpatient clinic of a large municipal hospital in New York, up to three patients with RAA, with a hematocrit between 18 and 30, were transfused during each of 1 or 2 weekly 8-hour sessions. The transfusion was initiated by an MD, who remained on call for emergencies. A RN observed the patient continuously. Adverse effects were managed by strict protocol.
Results. During the period from 7/87 until 1/89, a total of 604.5 units of packed RBC's were transfused in 66 patients with RAA (62 males, 4 females) including 51 homo/bisexual males, 10 patients with history of intravenous drug abuse, 3 with multiple AIDS-risks, 2 with other risks. 28 patients received transfusions on multiple occasions. Each patient was transfused an average of 3.7 units per session. Nine patients had indwelling catheters for access. Only 6 adverse effects were observed including 4 non-hemolytic febrile reactions, 1 severe allergic reaction, and 1 episode of hypotension caused by concurrent infection, resulting in hospital admission. There were 0.04 adverse reactions per patient transfusion session.
Conclusion. Transfusion therapy for patients with RAA can safely be provided in the outpatient clinic setting. Stable clinical status can be maintained in patients with RAA requiring transfusions without the need for admission to the hospital.

W.B.P.377 COMPLEMENTARY THERAPIES AT CASEY HOUSE HOSPICE: A MODEL FOR TRADITIONAL/ALTERNATIVE INTERACTION

William E. Berinati, M.A., D.C.
Chair, Complementary Therapies Committee,
Casey House Hospice Inc.
Vice-President, Casey House Hospice Inc.
Founding Board Member, Psychiatry Clinic for
AIDS-Related Concerns, Mt. Sinai Hospital, Toronto

The descriptors "alternative" and "traditional" regarding care of the HIV infected individual often suggests a dichotomy which can imply a rift between "medical" and "non-medical" orientation. Casey House Hospice made a firm commitment, from the outset, to utilization of "alternative" therapies in its hospital-affiliated program. This presentation will describe the philosophy, planning, and implementation of Complementary Therapies at Casey House, touching on the affiliation agreement with St. Michael's Hospital, educational aspects, and case studies involving a variety of therapies. The broader implications for both the overall treatment of HIV infected persons in the community or hospital setting and the marriage of the "traditional" and "alternative" health care systems will be introduced.

W.B.P.374 INTERFERON (IFN) ALPHA + AZT IN AIDS-ASSOCIATED KAPOSI'S SARCOMA (KS): FINAL RESULTS OF A PHASE I TRIAL.

Krown, S., Bundow, D., Gansbacher B, Gold J, Flomenberg N, Armstrong D. Memorial Sloan-Kettering Cancer Center, New York, NY USA.

Objective. To evaluate the safety, tolerance and maximum tolerated dose (MTD) of IFN-α + AZT in AIDS patients (pts) with KS; to assess antitumor, immunological and antiviral effects of the combination.
Methods. HIV-positive adults with biopsy-proven KS, PS≥70, ANC≥1500, Hb≥9.5 and no prior IFN or AZT were eligible. Cohorts of 4-6 pts were entered at various daily IM doses of IFN-α2a or N1 plus AZT, 100 or 200mg PO q4h.
Results. IFN-αN1 at a dose of 9x10^{6}U(MU) + 100 or 200mg of AZT induced dose-limiting toxicity in 4/6 and 4/4 cases, leading to discontinuation of this arm of the study; tumor response was seen in 3/6 and 1/3 evaluable pts, respectively. For IFN-α2a, a wider dose range was evaluated:

IFN Dose(MU/d)	AZT Dose(mg)	≥Grade 3 Toxicity/Eval.	CR+PR/Eval.	(%)
4.5	100	1/6	1/6	(17)
4.5	200	2/6	3/5	(60)
9	100	1/6	2/6	(33)
9	200	3/4	4/4	(100)
18	100	2/6	3/6	(50)

Two MTDs were defined: 4.5MU IFN-α2a QD + 200mg AZT q4h and 18MU IFN-α2a QD + 100mg AZT q4h. Neutropenia was the major dose-limiting toxicity. Skin test reactivity increased, while CD4 and CD8 cells declined. Of 7 pts with elevated serum p24 antigen, 6 showed a decline to undetectable levels.
Conclusion. IFN-α2a and AZT can be safely combined and induced a high tumor response rate and p24 suppression in some patients. (Supported by NIAID-ACTG)

Care

W.B.P.376 Self Care Nursing for AIDS/ARC via Computer Networks

Patricia Flatley Brennan, RN, PhD, Principal Investigator

Stefan Ripich RN, Project Director
Frances Payne Bolton School of Nursing, Case Western Reserve University

This three year study evaluates the use of a free, public access computer network as a vehicle for the delivery of nursing services in the treatment of Acquired Immune Deficiency Syndrome (AIDS) and AIDS-Related Complex (ARC). We proposed to augment traditional methods of nursing care delivery with a new approach that will (1) enable nurses to meet the informational needs of well persons concerned about AIDS/ARC; (2) foster self-care of people with AIDS/ARC ("PWA/PWARC") and their carepartners through in-the-home support, counselling, and education. Currently underway is a six month needs assessment involving 100 PWA's and their carepartners.

Computer networks create electronic links between remote sites. In this project we will put computers in the home of PWA/PWARC to provide links to clinical agencies or to other homes. Through these terminals people can access an existing computer system and use the special programs and communication services constructed to support the entire range of AIDS/ARC patients: healthy persons needing information, persons diagnosed with AIDS/ARC, and the informal care partners of PWA/PWARC. The messaging and support services will facilitate peer as well as professional contact, serving as a "support group without walls".

This intervention's effectiveness in disseminating information, enhancing problem solving skills, and diminishing isolation will be evaluated in a series of field studies. The increasing emphasis on non-institutional care demands new approaches to delivering treatment and support, while the availability of computer technology provides the means to do so. Preliminary findings from the needs assessment suggest that due to cognitive impairments computer interfaces employ icons (pictures) as well as text.

W.B.P.378 PROBLEMS IN AN AIDS HOSPICE SETTING

Bloom, Jeff A., Flannery, J.
Casey House Hospice, Toronto, Ontario, Canada

Casey House is a free standing hospice dedicated to people with AIDS. The Hospice has 13 beds (12 palliative, 1 respite care) and opened in March 1988. It was expected that the emphasis of medical/nursing care would be on symptom management (pain, nausea, skin problems and minor infections). Although the residents/legal guardians (for demented residents) accept the philosophy of palliative care, denial of their own situation often impacts on choices. In the first 11 months, Casey House has admitted 82 people. 58 have died and 12 have been discharged. The health and functional capacity of the residents in the House affect the criteria of the next admission. As acute health situations arise, residents may elect to be transferred to an acute care facility. Unexpectedly, some residents improve so they no longer require the level of care provided at the Hospice. Because their recovery was unexpected, discharge planning has been difficult. Community systems are not presently organized to assist these people. Problems occasionally arise regarding residents who wish to continue to use unapproved drugs or home remedies with which the care-providers are unfamiliar.
Conclusion: AIDS is much less predictable than cancer in the final stages. With everchanging approaches to therapy, all involved persons must be ever flexible in the definition and provision of palliative care. We must continually review the policies of the Hospice in accordance with changes in the disease and encourage change in the community to provide an effective continuum of care.

W.B.P.379 DEVELOPMENT OF A DAY FACILITY FOR PEOPLE WITH AIDS/HIV INFECTIONS

KELLY, ANN

Objective: The Kobler Centre, attached to St Stephen's Hospital, London, aims to provide day care for AIDS/HIV patients in order that the patients remain at home independently for longer than previously.

Method: A description of the commissioning and activities of the Centre during its first year of operation.

Result: The facility was constructed at a lost of £3.2 millions in eighteen months from planning to completion. It has 6 day beds and 5 consulting rooms for outpatients. The Centre performs endoscopies, minor procedures, blood transfusions and drug therapies.

Conclusion: The Centre has reduced pressure on hospital inpatient facilities and provided an environment that enables patients to maintain their independence and remain at home for longer than previously.

W.B.P.380 FONCTIONS DU PSYCHIATRE DANS UN HOPITAL DE JOUR POUR PATIENTS HIV+

LINARD Françoise ; SILVESTRE D.
INSERM U 158 - Hôpital Claude Bernard - PARIS

Objectifs : Evaluer le rôle du psychiatre dans un hôpital de jour recevant des patients HIV+, auprès des malades et au sein de l'équipe soignante.
Méthodes : 1) Consultations psychiatriques : 1/2 j/semaine x 2 ; 30 consultations/mois
Il s'agit d'entretiens psychiatriques soit uniques, soit répétés, voire de suivis psychothérapeutiques
2) Participation aux réunions de l'équipe soignante de l'hôpital (6 médecins et 10 para-médicaux...)
Résultats : Une année d'expérience montre que la demande a été en progression constante tout en se diversifiant. Il s'agit soit de traiter des manifestations d'angoisse et/ou de dépression souvent rencontrées chez ces patients, parfois même dans l'urgence ; soit de prendre en psychothérapie certains patients névrosés dont les symptômes ont été exacerbés du fait de la maladie et de son impact psychologique ; enfin de faire face à des décompensations psychiatriques graves, par un traitement médicamenteux. Le psychiatre peut être consulté aussi, à la demande du médecin, pour aider à discriminer la part psychogénétique et/ou organique de tel ou tel symptôme. Sa fonction ne peut se limiter à ces interventions. L'équipe soignante a besoin d'untiers dans la relation médecin-malade, même en l'absence de demande de soins spécifique. Lorsque règne une proximité trop grande avec les patients, une distance doit être rétablie pour le confort de chacun.
Conclusion : La fonction du psychiatre n'est pas univoque. Thérapeute de certains patients, il est aussi par rapport à l'équipe soignante en position de tiers, permettant une analyse déculpabilisante, ou désangoissante de certains comportements.

W.B.P.381 IMPLANTABLE INFUSION PORTS IN PATIENTS WITH AIDS

Johnston, Lynn*, Lynch, Y.**, Roy, P.***, Depts. of Medicine*, Nursing**, and Surgery***, Victoria General Hospital, Halifax, N.S. Canada.

Objective. To review our experience with the use of implantable infusion ports (PAC) in AIDS patients compared to their use in non-AIDS patients. Methods. Retrospective chart review of 15 AIDS and 16 non-AIDS (NA) patients who had a PAC inserted by the same surgeon. Results. Since 1987, 15 of our AIDS patients (all men, av. age 34.5 yrs.) have had PAC placement for future and current antibiotic use (15/15) and/or TPN (2/15) an av. of 30 (range < 1-120) wks. after their AIDS diagnosis. Ten were done under general and 5 under local anesthetic with antibiotic prophylaxis (11/15). The PAC remained in place an av. of 302.4 (range 9-706) days from the time of insertion to the endpoint (death, PAC removal, or Jan 31/89). Thirteen NA patients (all men; av age 40.4 yrs.) had hematologic or solid tumour malignancies. AIDS and NA patients had an equal number of readmissions (av. 3.3 vs 3.4) with use of PAC (77.6% vs 78.2%) and little need for other IVs (10.2% vs 10.9%). In 2 AIDS and 1 NA patients there were difficulties with PAC insertion; in all 3 the tubing was subsequently replaced or removed. None of the AIDS and 7/16 NA patients had PMN counts < 500; 6 AIDS and 2 NA patients had bacteremias (2 and 1 line-related, respectively). In only 1 (AIDS) patient was the PAC removed because of infection. There were no other complications in either group. Conclusion. PAC insertion provided safe and convenient longterm venous access in AIDS patients.

W.B.P.382 FOLLOW-UP OF INFANTS BORN TO HIV-INFECTED MOTHERS IN ARGENTINA.

Messa, B*; Gómez Carrillo, M**; Albani, M*; Reposo, N*; Sala, A*; Fernandez, M*; Balbaryski, J*; Boxaca, M**; Weissenbacher, Mercedes**.
*Pedro Elizalde Hospital; **Department of Microbiology, School of Medicine, Buenos Aires. Argentina.

Objective. To determine the risk factor and the serological, immunological and clinical evolution of the new-borns of HIV-positive women.
Methods. A group of 8 infants born to HIV-infected women were admitted to a Children's hospital in Buenos Aires City between December 1987 and March 1988. They were studied clinically, immunologically and serologically every 3 months. Anti-HIV antibodies were studied by EIA, gelatine agglutination IF and Western blot techniques.
Results. 6 of the infants studied were born to IVDA women, and admitted to the hospital 24 hours after births performed by caesarean. In 5 of these cases the father was IVDA - HIV-positive and in 1 case the father was unknown. The remaining 2 babies were abandoned at 20 and 30 days old, their mothers were prostitutes and the fathers unknown. The clinical follow-up performed until 9-14 months of age showed in 6 of the babies a ponderal and neurological development corresponding to normal standards (1 of them developed withdrawal symptoms). The immunological profile was normal in the 6 infants during the follow-up. The only baby to arrive undernourished died 1 month later of a sepsis and the last one abandoned the follow-up. The initially very strongly positive screening and supplementary tests changed to negative or with fading intensity in the following months.
Conclusion. Of 8 HIV positive babies interned in a Children's hospital of Buenos Aires City 75% were born to HIV-positive IVDA mothers and the remaining 25% to HIV-positive prostitutes. One of the 8 babies died 1 month after admission to the Hospital, another could not be followed further and the remaining 6 showed normal clinical and immunological development with disappearance or a drastic decrease in the anti-HIV antibodies.

W.B.P.383 THE IMPACT OF AIDS ON FAMILIES OF HAEMOPHILIACS IN WALES

Beese, Jacqueline, University of Wales College of Medicine, Cardiff, South Wales, U.K.

Objective. To describe the impact of Aids on the familes of affected Welsh Haemophiliacs.
Anyone involved with haemophiliacs has to be impressed by their courage in getting on with the business of living in spite of the debilitating nature of the disease. Now over fifty individuals living in Wales are facing a new obstacle - HIV infection as a result of contaminated blood products; five have already died. The sex linked mode of inheritance means that more than one family member may be affected. Method. The data on which the study is based was collected over a period of twelve months from the families of adult males and children attending a haemophilia centre. The qualitative holistic approach of grounded theory is used to explain the subjective dimensions of their human experiences. Results. At least one wife has seroconverted, others have not made love since their husbands were found to have contracted the Aids virus, largely due to the fact that their husbands recoil from physical contact for fear of infecting their wives. They are experiencing enormous strain. Parents have a huge burden to bear, some have experienced publicity surrounding the death of a child, several having other affected children face stigma and social isolation, others live in fear of being identified. Conclusion. Marriages are under stress, there is evidence of poor communication between partners who frequently keep the knowledge to themselves. A number have turned to drink or drugs in an effort to come to terms of their plight.

Th.B.P.1

LYMPHOCYTES CYTOCHEMISTRY BEHAVIOR IN HEMOPHILIC PATIENTS WITH HIV INFECTION.

Gabriella Gamba, S.Testa, L.Ponchio, R.Invernizzi P.Di Fazio, G.B.Ippoliti. Dipartimento di Medicina Interna e Terapia Medica, Sez.di Clinica Medica II. IRCCS Policlinico San Matteo. Università di Pavia. Italy.

The cytochemical and immunological characterization of lymphocytes of 31 hemophilic patients (6 of whom anti HIV positive without symptoms and signs of AIDS) chronically treated with commercial clotting factor concentrates were studied. In comparison to aged cross matched male controls, haemophiliacs presented significant increase of absolute number of lymphocytes and of subpopulation of T cells (CD_3 ,CD_4 ,CD_8) and of B cells (Ia_1 ,CD_{20} ,sIg). PAS reaction showed a lower grading score in haemophiliacs and the staining for α-naphtyl butyrate esterase(NBE), acid phosphatase(AP), N-acetyl-β-glucosaminidase (NABG), gave significant reduction of the percentage of the lymphocytes with coarse granules in the same pts. The percentage number of AP reactive lymphocytes with coarse granules was directly related to the percentage number of CD_3 and CD_4. The anti HIV positive pts presented lower percentages of CD_4 and of dot-like AP reactive lymphocytes. In conclusion we suggest that acid hydrolase cytochemistry, expecially the Dot-like AP reaction, may represent a useful, simple and unexpensive method for following modification of CD_4 subset in pts at risk of developing AIDS.

Th.B.P.2

ANTIPHOSPHOLIPID ANTIBODIES AND HIV INFECTION IN HEMOPHILIA.

Sofia Testa, L.Ponchio, N.Montani, C.M.Montecucco*, G.Cascone, G.Gamba. Dipartimento di Medicina Interna e Terapia Medica, Sez.di Clinica Medica II e *Sez. di Patologia Medica. IRCCS Policlinico San Matteo. Università di Pavia. Italy.

Objective: to study the presence of antiphospholipid antibodies: lupus like (LAC) and anticardiolipin (ACA) in Hemophilia. Patients: 30 pts. with Hemophilia A. 6 pts. with Hemophilia B; 9 pts. positive for anti-HIV antibodies, without symptoms and signs of AIDS. Methods: LAC diagnosed by prolongation of Russell Viper Venom Time (RVVT), not corrected by adding of normal plasma. ACA detected by Immunoenzimatic Test (ELISA), using POD coniugated with anti-murine antibodies against human IgG, IgA, IgM. Results: we detected ACA in 8 out the 9 pts. with HIV infection and in 4 of them also LAC. Among the anti-HIV neg pts. only 4 showed ACA and 2 LAC. In pts. with ACA no correlation was found between serum Ig levels and IgG ACA. Prevalence of IgG ACA was observed in anti-HIV pos pts. (87.5%) while IgM ACA in HIV neg ones(75%9). Conclusions: our data suggest that in Hemophilia: 1)HIV infection induces the production of antibodies against phospholipid components; 2)different behavior of ACA Ig Isotypes (IgG, IgM) was observed in relation to the presence of HIV infection; 3)HIV infection promoves the formation of ACA earlier than of LAC.

Th.B.P.3

ABSENCE OF HIV-2-INFECTION IN HEMOPHILIA IN BUENOS AIRES

María Belén Bouzas*; Simon, F**; Muchinik, G*; Picchio, G*; Brun Vezinet, F**. Mathov I. *
*IIHEMA, Academia Nacional de Medicina, Buenos Aires, Argentina, **Hopital Claude Bernard, Paris, France.

Objective. Since HIV-2 probably spread via the same transmission routes as HIV-1, and considering that our patients received American and European concentrates, we evaluated HIV-2 antibodies in hemophiliacs previously screened for HIV-1.

Methods. Presence of HIV-2 antibodies was investigated in the sera of 60 hemophiliacs: 33 HIV+, 27 HIV-. Sera were screened for HIV-2 antibodies by an ELISA assay (ELAVIA 2) (Diagnostics, Pasteur). Samples repeatedly positive or undeterminated were tested by RIPA.

Results. None of the 60 sera was HIV-2-positive when confirmed by RIPA; however, 21 samples were initially considered positive in the ELISA assay. No sample could be confirmed when tested by RIPA.

Conclusion. Although the number of tested sera does not allow to ascertain conclusions, it seems HIV-2-infection is very infrequent in this high-risk group in Argentina.

(Supported by a grant from Fundación Roemmers).

Th.B.P.4

HIV-INFECTION AND CHAGAS' DISEASE IN HEMOPHILIACS IN ARGENTINA

Bouzas, María Belén*; Corral, R**; Muchinik, G*; Grinstein, S**; Campestri, R*; Pérez Bianco, R*, et al.
*IIHEMA, Academia Nacional de Medicina, **Hospital de Niños, Buenos Aires, Argentina.

Objective. To analyze the relation between HIV-infection and Chagas' disease (CH) in 72 hemophiliacs (HF).

Methods. HIV serology was assayed thru ELISA (Abbott, recombinant). Positively reacting samples were confirmed thru Immunofluorescence or Western Blot (Dupont). CH diagnosis was performed by means of direct agglutination and indirect hemoagglutination assays (Polychaco). Titers > 1:16 for both serologic tests were considered positive.

Results. Twenty-two out of 37 HIV-1 positive sera showed a positive test for CH. In addition, 18 out 35 HIV-1 negative sera gave a negative reading in the CH assay.

Conclusion. Ch is an hemoparasitosis, endemic for our country. Blood transfusions constitute one of the major ways of dissemination. Ch shows the same prevalence on HIV-1 positive and HIV-1 negative HF ($p > 0.05$). Similar results were observed in other HIV-1-risk groups, such as homosexuals (30) and drug abusers (30). By contrast with the reported occurrence of other endemic diseases (for ex., tuberculosis) as second opportunistic infections, in our series infected patients did not present higher susceptibility to CH than that exhibited by HIV-1 negative HF.

Th.B.P.5

RESPONSE TO HEPATITIS B IMMUNIZATION IN HEMOPHILIAC CHILDREN: RELATIONSHIP TO HUMAN IMMUNODEFICIENCY TYPE I (HIV-I) VIRUS INFECTION.

Chan, Wendy, Petric, M[1], Wang, E, Koren, G, Read, S., Blanchette, V.. Departments of Pediatrics and Virology[1], Hospital for Sick Children, Toronto, Ontario, Canada.

Hemophiliacs who receive pooled plasma concentrates for control of bleeding are at high risk for hepatitis B infection. In our Hemophilia Clinic, children susceptible to hepatitis B infection (-ve HB$_s$Ag; -ve anti-HB$_s$Ag) have been immunized using a plasma-derived hepatitis B vaccine (Heptavax-B® Merck Sharp and Dohme). Three injections are given at 0, 1 and 6 months. We now report serial anti-HB$_s$Ag titres, measured by radioimmunoassay (Ausab®, Abbott), in a population of 23 children with hemophilia A (n = 19) or B (n = 4). Twelve of the children were HIV-1 antibody +ve (11 CDC Group II/III, one Group IV-E), and 11 were HIV-I antibody -ve. The median age of the HIV-I positive and negative groups were 5.6 and 5.3 years respectively (range for both groups 9 months to 13 years, 8 months). Results are as follows:

Time from start of Hepatitis B Immunization (months)	HB$_s$Ag Antibody Titres (RIA Units)		
	HIV-I Positive	HIV-I Negative	P
12-24	11147 ± 18983	43686 ± 53960	≤0.05
25-36	3127 ± 4384	25996 ± 29685	≤0.01
37-48	1724 ± 2275	22611 ± 21069	≤0.005

Values are means ± 1 S.D.

At the time of reporting, anti-HB$_s$Ag titres have fallen below protective levels (< 40 RIA units) in 4 children (3 HIV-1 +ve, 1 HIV-1-ve). One HIV-I positive child, not included in this series, failed to respond to immunization. We conclude that hemophiliac children with HIV-I infection have an impaired response to hepatitis B immunization. In such children, follow-up of anti-HB$_s$Ag titres at completion of immunization and yearly thereafter is recommended.

Th.B.P.6

BENEFICIAL EFFECT OF AN ULTRAPURE FACTOR VIII CONCENTRATE ON HYPERGAMMAGLOBULINEMIA IN HIV-POSITIVE HEMOPHILIACS.

Schulman, Sam and Johnsson, H.
Dept of Internal Medicine, Karolinska Hospital, Stockholm, Sweden.

Objective. Elevated IgG-levels are often seen in hemophiliacs. The etiology is multifactorial, including passive transfer of IgG via the factor concentrate, allogenic stimulation by foreign proteins, chronic hepatitis and HIV-infection. Until recently the concentrates contained a multitude of plasma proteins and <1% of F VIII. Since 1987, we have had access to an ultrapure factor concentrate, containing only F VIII and albumin.

Methods. Immunoglobulin G, A and M were followed at 3 months intervals since 1985 in 17 HIV-positive patients. Nine of those were switched to an ultrapure factor concentrate (Hemofil M, Baxter) during Aug 87 - Apr 88. The remaining 8 patients ("control group") continued using conventional concentrates. Results were analysed with Wilcoxon's signed rank test.

Results. The mean IgG-level in the Hemofil M-group increased from 16.4 in 1985 to 20.6 at the time they were switched to Hemofil M ($p=0.05$) and then decreased during the following year to 17.9 ($p=0.02$). In the control group the mean IgG-level was, at corresponding times, 15.6, 19.2 and 18.7, thus also an initial increase ($p=0.02$), but thereafter no change. In the Hemofil M group it was mainly the 3 patients with the highest IgG-levels (23.0; 29.7 and 37.6 g/L), who had a beneficial effect. The last one also had pulmonary hypertension, which improved simultaneously. IgA and IgM did not change.

Conclusion. Switching to an ultrapure factor concentrate seems to have a favourable effect in HIV-positive hemophiliacs, especially in those with pronounced hypergammaglobulinemia.

Th.B.P.7 HEMOPHILIA, SEPTIC ARTHRITIS AND HUMAN IMMUNODEFICIENCY VIRUS

Jarzem, Peter*; Tsoukas, C*; Burke, D*; Strawczynski, H*; Growe, G**; Poon, M-C***. Universities of *McGill, **British Columbia, *** Calgary, AB, Canada.

Objectives: Recent clinical observations have led us to believe that the incidence of septic arthritis (SA) in the hemophiliac population has risen sharply. To confirm this and determine the cause we examined the records of patients enrolled in the Canadian National Hemophiliac Study (CNHS).
Population Studied: 372 patients were enrolled in the study. No cases of SA were noted among HIV seronegatives. 170 were HIV seropositive of whom 7 had a total of 8 episodes of documented septic arthritis (incidence of 4.7%). A literature search spanning 40 years revealed 18 cases of SA in hemophiliacs (incidence < 0.1%).
Results: All of the patients had severe classic hemophilia. Infections were diagnosed late and associated with significant morbidity. The most common infectious agent was *Staphylococcus aureus*, although *Staphylococcus epidermidis* and *Neisseria meningitidis* each accounted for an infectious episode. The clinical course of the joint disease was difficult to distinguish from a hemarthrosis, but in every case of SA the patient was febrile and poorly responsive to factor concentrate (AHF) therapy. The peripheral leukocyte count averaged $5.9\ 10^9$/L, and was not a good indicator of sepsis.
Conclusion: HIV seropositivity correlated with a marked increase in the incidence of SA among hemophiliacs. This incidence will likely increase as more patients develop CDC group IV HIV disease. We suggest 1) that strict attention be paid to sterile technique with self infusion of blood products, 2) any hemophiliac with prolonged joint pain unresponsive to AHF therapy or fever should undergo immediate arthrocentesis to rule out septic arthritis.

Th.B.P.8 LONGITUDINAL ANALYSES OF HIV-SPECIFIC ANTIBODY RESPONSES IN HEMOPHILIACS WITH LONG-TERM HIV INFECTION

Phyllis Flomenberg[1,2], W. Honnen[4], K. Revesz[4], H. C. Chen[4], Angela Choy[4], M. Hilgartner[3], J. Conway[3], and Abraham Pinter[2,4]. [1]New York Veterans Administration Medical Center, [2]New York University Medical Center, [3]Cornell University Medical Center, [4]The Public Health Research Institute, New York, New York, U.S.A.

Objectives. To identify parameters of the serological response to HIV which may correlate with prognosis, using sequential bleeds from a 40 hemophiliacs, infected for an average of seven years.
Methods. Titers of antibodies against specific HIV antigens were determined by a sensitive radioimmunoprecipitation assay (RIPA), using ^{125}I-labeled viral lysates (Pinter and Honnen, J. Immun. Methods *112*, 235-241). Neutralization titers were determined with a quantitative, 24 hour immunofluorescent focus assay which we have developed.
Results. Three major RIPA patterns were detected in the group of patients studied. In 26 patients, antibodies to all major HIV structural proteins (gp120, RT, gp41, p24, and p18) were always present (pattern a). In 11 patients, antibodies to p24 disapppeared over time, whereas all other antibodies persisted (pattern b). Notably, 3 patients were identified who never made antibodies to p24, but did have antibodies against all other components (pattern c). Most patients with patterns 'b' and 'c' (9/14) developed T4 counts < 400, and approximately a third of each of these groups have ARC or AIDS. In contrast, only 2/26 of patients with pattern 'a' have ARC. Antibody titers to other antigens were stable for most patients. However, in two patients with AIDS, the loss of antibody to p24 was followed by a 10-fold decrease in antibodies to all other viral antigens. In preliminary tests, varying levels of neutralizing titers were detected in all patients, but no direct correlation was observed between levels of neutralization activity and clinical status. Two unique patients were identified with high neutralizing titers (1:1000-1:1500), who developed progressively increasing anti-p24 titers over a period of 7 years. Both patients have remained asymptomatic with normal T4 counts.
Conclusions. A general, but not absolute correlation was observed between lack of reactivity or loss of antibodies against p24 and disease progression. The presence of both high titers of neutralizing antibodies and increasing titers of anti-p24 correlated with good clinical status.

Histoire clinique de l'hémophilie
Hemophilia: Natural History

Th.B.P.9 ETUDE PROSPECTIVE D'UN GROUPE DE 28 JEUNES HEMOPHILES INFECTES PAR LE VIRUS VIH.

Tricoire Joëlle*, Robert, A*, Puel, J**, GAYET, C**, Boneu, B*** Régnier, C*
* Pédiatrie B, CHU Purpan, 31059 Toulouse Cédex, France; ** Laboratoire de Virologie, CHU Purpan, 31059 Toulouse Cédex, France; *** Centre de Transfusion sanguine, Toulouse 31300 Toulouse, France.

Objectif. Etude prospective sur 3 ans de l'évolution clinique et biologique de 28 hémophiles âgés de 9 à 20 ans (M : 14 ans) infectés par le virus VIH.
Méthode. Les bilans cliniques, biologiques sont effectués tous les 6 mois. Ces derniers comprennent une étude hématologique, immunitaire et virologique (Western Blot, IgG, IgM, dosage de AC p24, Ac gp41 et Ag p24).
Résultats. Cette étude nous permet de noter :

- une évolution clinique pour le stade III de 11 à 66 %
- une baisse régulière des T4 : T4 500/mm3 de 32 à 46 %
- la présence de l'Ag p24 : de 6 à 18 %
- la disparition de l'Ac p24 : de 15 à 53 %

La répartition des enfants dans 2 groupes suivant le taux des T4 pris au début de l'étude (groupe I : T4 500/mm3 ; groupe II : T4 500/mm3), nous montre une progression plus rapide du groupe I par rapport au groupe II. Pour 10 autres enfants, nous n'avons pas un recul suffisant pour pouvoir les inclure dans l'étude et parmi eux deux sont décédés de SIDA (6 %)
Conclusion. Sur 3 ans, le potentiel évolutif chez 28 jeunes hémophiles infectés est inquiétant et rejoint l'évolution constatée dans les autres populations à risque.

Th.B.P.10 IMMUNOLOGICAL AND VIROLOGICAL FINDINGS IN PARADOXICAL HIV1 SERONEGATIVE MULTI-TRANSFUSED HAEMOPHILIACS (1983-1989)

Barthier A.[1] Chamaret S. [2]Ameisen J.[3] Laure F. [4] Gr. Rennais de recherche sur le SIDA. Montagnier L.[2] 1 - Centre Rey-Leroux 35 La Bouexière 2 - I. Pasteur PARIS - 3 - I. Pasteur LILLE - 4 - CHU NECKER PARIS - FRANCE

Absence of anti gag/anti env Ab. seroconversion in a number of multitransfused haemophiliacs (treated before 1985 with the same blood products as seropositive haemophiliacs), appears paradoxal. In this view an immunological and virological study was conducted in 30 seronegative haemophiliacs (replacement therapy before 1985 : FVIII or FIX conc. > 10 000 IU).
METHODS : HIV1-HIV2 Ab. (ELISA : W.B.), HIV_1p25 Ag. (ELISA), Anti-nef Ab. (W.B. - RIA).
Immunological study : CD4-CD8, Ly. functional assays, Iglob., β2m, IFN system ...
Immunological study : As early as 1983-84, immunological disorders were observed in some sero(-) haemophiliacs such as : decreased CD4 ly in 13% of seronegative patients, abnormal proliferative response to recall Ag. in 18%, diminished IFN γ production in 50%, high β2m level in 58% (>2mg/L).
The long term study (1985-89) shows persistent disorders in the same patients (CD4 < 400 in 8/30, IgA > 4 g/L in 6/30 and β2m > 3 mg/L in 8/30...) suggesting a possible HIV1 latent infection and therefore prompted us to look at new virological markers (albeit all patients were asymptomatic).
Virological findings :

- Absence of HIV1 p25 Ag. and HIV2 Ab. (1985-89) in all seronegative patients.
- 2 anti gag/anti env Ab. seroconversions in 1986 (ie 1 y. after use of treated concentrates).
- Anti-nef Ab. in 1983 in 1 patient who seroconverted in 1986 only.
  . in 1987 in 2 persistently sero(-) haemophiliacs (HIV_1 DNA sequences detected in 1/2)

CONCLUSION : Delayed seroconversion in 2 haemophiliacs (latent phase 1-3 y) and detection of anti-nef Ab. in 2 persistently sero(-) haemophiliacs (contamination confirmed in ½ by detection of HIV1 DNA sequences), and in addition anti-nef Ab. detection in 1979 in 2 haemophiliacs who seroconverted in 1982 only, as well as in 3 sero(-) sexual partners, provide arguments in favour of HIV1 latent infection, not revealed by conventional tests, in individuals with known exposure.

Th.B.P.11 EVOLUTIVITE DE L'INFECTION AU VIRUS DE L'IMMUNODEFICIENCE HUMAINE CHEZ 69 HEMOPHILES SEROPOSITIFS.

Ferrer Le Coeur, Françoise*; Meyohas, M.C.**; Hivert, Ph.*; Eliaszewicz, M.**; Lebas, J.** et Frottier, J.**.
* Centre National de Transfusion Sanguine (CNTS) ; ** Hôpital Saint-Antoine, Paris, France.

Objectif et patients. L'infection au virus de l'immunodéficience humaine (VIH) est analysée chez 69 hémophiles séropositifs, soit 38% de la population des déficits congénitaux suivis au CNTS. La répartition entre hémophile A (78%) et B (22%) est classique ; les adultes représentent 74% des patients.
Résultats. La classification CDC de cette population isole 41 asymptomatiques (stade II), 12 porteurs de lymphadénopathies (stade III) et 16 SIDA (stade IV) (23%) dont 3 sont décédés. Dix patients sont traités par la Zidovudine dont neuf depuis plus de 6 mois. Tous correspondent au stade IV. La posologie est de 1200mg/24 heures. La compliance est bonne. On observe une reprise de poids chez 6 patients avec une amélioration de l'indice de Karnofsky pour 5/9. Il a été observé 7 infections opportunistes (4 patients). L'antigénémie P24 positive 5 fois sur 9 s'est négativée dans 3 cas ; son taux a diminué dans deux cas. L'augmentation du nombre des lymphocytes CD4, constatée chez 6 patients, a été transitoire pour trois d'entre eux.
Conclusion. La date de séroconversion vis-à-vis du VIH des hémophiles en France est située entre 1982 et 1984. L'évolution de la maladie dans cette population semble identique à celle des autres groupes à risques.
L'hémophilie et ses accidents hémorragiques ne sont pas modifiés par le VIH mais le retentissement psychosocial de l'infection sur cette population est important.

Th.B.P.12 PROGRESSION OF HIV-INFECTION IN 46 HEMOPHILIC PATIENTS

Brunkhorst, Ulrike; Tschechne, B.; Barthels, M.; Schedel, I. and Deicher, H.
Hannover Medical School, Hannover, F.R. Germany.

Objective. To study the incidence of AIDS in relation to progression parameters in hemophilic patients.
Methods. 47 patients (age 13-58) who seroconverted between 1982-84 were examined during 24 mo (1987/88). CDC stage and the following parameters were documented: p24 antigen, disappearance of p24 antibodies, CD_4^+ cells < 400/ul, elevation of IgA, pathological ESR and number of thrombocytes < 150.000/ul.
Results.

CDC	II	III	IV	total
1987	n=13 (28%)	n=23 (50%)	n=10 (22%)	n=46 (100%)
1988	n=13 (28%)	n=21 (46%)	n=12 (26%)	n=46 (100%)

3/46 patients died of opportunistic infections. The investigated progression parameters were significantly more frequent in stage IV patients compared to the lower CDC stages (II 0-3, III 0-4), IV 4-6). In the two patients who progressed later to stage IV, 4 of 6 parameters were found, whereas in the other 21 patients of stage III only 0-3 parameters could be recorded.
Conclusion. In a group of 46 HIV-infected patients 25% have progressed to stage IV during 4-6 years observation period. In hemophilics as in patients of other risk groups additional parameters may help to identify patients with high risk for progressive disease.

Th.B.P.13

CLINICAL SIGNS AND DEATH CAUSES IN HIV + HEMOPHILIACS (hem) WITH PROGRESSING DISEASE

Pérez Bianco, R;Anselmo, A;de Tezanos Pinto,M;Muchinik Guillermo;Bouzas, MB;Rickard,E
IIHEMA, Academia Nacional de Medicina, Buenos Aires, Argentina.

Objective: To study clinical signs of hem with AIDS.
Methods: Up to January, 1989, 467 hem were studied:407 Hemophilia A (HeA) (87.15%) and 60 Hemophilia B (HeB) (12.85%). HIV antibodies were detected in 158 hem (33.83%) thru EIA(Abbott) and confirmed thru IFA and ENVACORE (Abbott).
Results: Out of the 158 hem,37(23.41%) - 32HeA (86.48%) and 5HeB (13.52%)-developed AIDS; 75%HeA (24/32) and 80% HeB (4/5) are severe. In frequency order, infection signs were: 8 candidiases,8Pneumocytis non-CMV,7CMVs,4TB, 3 Gram + sepses, 3 long-lasting fever syndromes without focus,2salmonelloses, 2 shigelloses,2 histoplasmoses,2nocardioses,2 Herpes Zoster, 1 brain acute Chagas',1strongyloidiasis, 1enteropathogenic streptococcus,1Pneumocystis carinii,1 slim disease; 2 cancers were diagnosed: a) pial cerebrospinal carcinoma, and b) undifferentiated adenocarcinoma metastasis.
Conclusion: The low number of Pneumocystis carinii cases microbiologically recorded may be due to the fact that hem cannot be subjected to invasive techniques. Out of the 37 AIDS hem, 19 (51.35%) died. Oral candidiasis was the most frequent sign observed and CMV was the agent causing the death of 7 patients.

Th.B.P.14

HEMOPHILIAC POPULATION OF COSTA RICA FROM 1979 to 1989

Taylor, Lizeth*; Montero, C.**; Cordero, R.**; Astua, M.C.**; Roy, A.*; Luftig, R.***; Visona, K.A.*
*Louisiana State University-International Center for Medical Research & Training, (LSU-ICMRT), San Jose, Costa Rica; **Hematological Dept., Hospital Mexico, San Jose, Costa Rica; ***LSU Medical Center, New Orleans, Louisiana, U.S.A.

Objective: To analyze the serological profile in the hemophiliac population in Costa Rica.
Methods: Serum samples stored in the LSU-ICMRT serum bank were tested with anti-HIV ELISA (Abbott HTLV-III), Western Blot (LSU-ICMRT), HIV antigen (vironostika-Organon), IRMA HB_sAg and anti-HB_s (LSU-ICMRT). Clinical data were obtained from the hospital case files.
Results: Of the 147 hemophiliacs, 80 (54%) were positive for either HB_sAg or anti-HB_s. 64 (44%) were positive for anti-HIV-1 with the following distribution:

Anti-HIV-1	Hemophilia A	Hemophilia B	Hemophilia C	Von Willebrand
Positive	44	18	0	3
Negative	46	3	2	31
TOTAL	90	21	2	34

Sixteen (36%) of the A hemophiliacs were anti-HIV-1 positive since 1980 or before, while 11 (55%) of the B hemophiliacs were positive since 1986. HIV-1 antigen test was done in 59 of the 64 anti-HIV-1 positive hemophiliacs whose sera were available. The presence of the HIV-1 antigen was evaluated in correlation with seroconversion, development of ARC or AIDS and death of the hemophiliac.
Conclusion: The analysis of HIV-1 seropositivity in Costa Rican hemophiliacs provides some new insights into the origin of this disease in Central America.

Th.B.P.15

AN IMMUNOLOGICAL FOLLOW-UP IN HEMOPHILIC NON-CONVERTERS AFTER TREATMENT WITH AN HIV-CONTAMINATED BATCH.

Schulman,Sam* and Berntorp, E**.
Depts of Internal Medicine, *Karolinska Hospital, Stockholm, and **Malmö General Hospital, Malmö, Sweden.

Objective. In 1985 four Swedish hemophilia B-patients were infected by a batch of a F IX-concentrate, contaminated with HIV. Another 11 patients -the "risk group", treated with the same batch, did not show seroconversion for anti-HIV. We have followed them carefully for signs of HIV-infection, and we have compared them with 20 hemophilia B-patients, who did not receive this batch -the "control group".
Methods. Anti-HIV was checked at least annually. T-lymphocyte subsets (CD4 and CD8) were also analysed annually.
Results. No seroconversions have occurred since 1985 in any of the patients. The CD4 number and the CD4/CD8-ratio have not decreased, neither in the risk group, nor in the control group.
Conclusion. During a 3-year follow-up we have not identified any late seroconversions or signs of false anti-HIV-negative cases in a cohort of 11 hemophiliacs, treated with a contaminated batch of F IX-concentrate.

Th.B.P.16

NATURAL HISTORY OF HIV INFECTION IN LARGE HEMOPHILIA COHORT: FOLLOW-UP SINCE 1983; 1988/89 UPDATE.

Beth-Giraldo, E.*; Miraglia, E.**; De Biasi, R.**; Rocino, A.**; Martucci, F.*; Giraldo, Gaetano*. *Ist. Naz. Tumori "Fond. Pascale" and **Center Med. Soc. Hemophilia, Osp. N. Pellegrini, Naples, Italy.

Objective. Multidisciplinary longterm follow-up studies on a large cohort of subjects (>100 HIV+ of 280 patients) with coagulation defects to establish the effect and outcome of HIV infection and co-factors in hemophiliacs.
Methods. Immunologic and virologic profiles are evaluated twice yearly and correlated with clinical presentation in order to determine the natural history of HIV infection (abstr.: Paris '86, Wash. '87, Stockholm '88, Beth-Giraldo et al., S. KARGER, A.G., 1987).
Results. Infection by HIV-1 has persisted in >98% of HIV+ patients in f.u.

Clinical stage	1985/6	1986/7	1987/8	T4 mm^3	1988/9	T4 mm^3
Asymptomatic	51%	42%	24%	371	22%	324
LAS	40%	42%	55%	311	50%	331
LESSER AIDS	9%	11%	11%	192	7%	277
AIDS	0%	5%*	10%		21%	

* 1 patient with hemophilia A developed AIDS/KS

Conclusion.Follow-up will continue in order to correlate immunologic profile with virologic responses to HIV, EBV, CMV, HHV-6, HSV and HTLV-I, particularly in HIV+ asymptomatic patients and patients with persistent T4 cells↑.

Th.B.P.17

NATURAL HISTORY OF HIV INFECTION IN A GROUP OF HEMOPHILIACS WITH KNOWN YEAR OF SEROCONVERSION

Karafoulidou,Anastasia*;Gialeraki,A.*;Hatzakis, A.**;Economidou,J.***;Psarra,K.***;Markakis,C.*;Makris,P.*; Mandalaki,T.*.
*Laikon Hosp.,Athens,Greece, **Athens Univ. Medical School, Athens,Greece, ***Evangelismos Hospital,Athens,Greece.

Objective. To determine the incidence of the serious clinical outcome of HIV infection and to assess various prognostic markers of progression.
Methods. Seroconversion to HIV was documented by ELISA and WB or RIP in 42 hemophiliacs. The seroconversions occured between 1980-1985.
Results and Conclusions. By November 1988,4 cases of AIDS or ARC2 (ARC plus T4<200μl) have been diagnosed (Incidence Rate 18 cases/1000 person-years).However 10 out of 35(28.6%) cases developed WR5 or WR6 stage of the Walter Reed classification system. A steady decrease in the absolute number of the T4 lymphocytes was noted between follow-up years 1-5 but the gradient was slower between years 6-8.Declining titers to antibody p24 was an earlier prognostic marker of poor clinical outcome or immunologic deterioration compared to p24 antigen and the loss of anti-p24 reactivity usually occured 1 year before the appearance of p24 antigen.

Th.B.P.18

HIV-1 INFECTION IN CHILDREN WITH HEMOPHILIA A AND B. A REPORT FROM THE CANADIAN PEDIATRIC HEMOPHILIA AIDS STUDY GROUP.

Blanchette, Victor
The Hospital for Sick Children, Division of Hematology/Oncology, Toronto, ON, Canada.

A survey of HIV-1 antibody +ve pediatric hemophiliacs (age ≤ 18 years on 01/01/89) followed in comprehensive care hemophilia clinics in Canada, was conducted in January 1989. Seventeen Centres in 9 Provinces are represented in this report. The results of the survey are as follows:

FACTOR DEFICIENCY	VIII: C		IX	
	≤1%	≥1%	≤1%	≥1%
Ontario	102*(43/101)**	78 (4/78)	21 (11/21)	22 (2/22)
Quebec	63 (30/63)	49 (4/49)	5 (0/5)	14 (0/14)
Eastern Canada	14 (4/12)	62 (6/41)	0 (0/0)	6 (1/5)
Western Canada	32 (13/31)	33 (4/18)	9 (0/3)	17 (0/7)
	211 (90/208)	222 (18/186)	35 (11/29)	59 (3/48)

*Number of cases followed ** # Western blot confirmed HIV-1 antibody +ve cases/# tested. Twenty six% (122/471) of the pediatric hemophiliacs identified in this survey are HIV-1 antibody +ve. Seropositivity was higher in children with severe vs mild/moderate hemophilia (42.6 vs 8.9%), and in children with factor IX deficiency followed in the Province of Ontario as compared to elsewhere (52 vs 0%). Two patients have developed AIDS; one of these cases died of an intracranial haemorrhage related to trauma. Four children are currently on AZT [CDC Group:II (1), IVC-1(1), IVC-2(1), IV-B(1)]. In 55 hemophiliac children followed in one Ontario Centre, 11 cases have declining p-24 antigen levels and CD4 cell counts less than 200/μl, findings associated with a poor prognosis in adult seropositive hemophiliacs. We conclude that criteria for use of AZT in pediatric hemophiliacs are urgently needed, and efforts to formulate a National policy are currently underway.

Th.B.P.19 HEMOPHILIAC AGE AFFECTS IMMUNE FUNCTIONS IN HIV INFECTED PATIENTS.

Andes, W. Abe*; Wulff, K.*; Lemoine, C.*; Deul, C.**; Morgan, J.**; DeShazo, R.D.**; et al.
*The Louisiana Comprehensive Hemophilia Care Center, **Tulane University School of Medicine, The Louisiana State University School of Medicine, Department of Pediatrics and the Tulane/LSU ACTG, New Orleans, Louisiana, USA.

We have followed approximately 200 hemophiliacs (H) at our State Center since 1980. Overall 55% (103) of the patients who used any non-treated factor VIII or IX concentrates seroconverted. Of those children (C <13) 29/99, adolescents (Ado <18) 22/45, and adults (Adu) 52/117 developed specific HIV antibodies. C (n=5) took longer to asymptomatically develop T4's <500 but without AIDS than Ado's (n=6) or Adu's - 60, 28, and 37 months respectively (p <0.01). Of those whose T4 cells declined to <500 this reduction occurred at a rate of approximately 20 (11-36) T4 cells per month. Eight patients have been followed for a total of 122 man-months with <200 T4 cells without developing disease though 8 others suffered AIDS with such low numbers. Fourteen patients - 3 C, 1 Ado, and 10 Adu - have developed AIDS after a period of 23-75 months following seroconversion. Of 41 H who remain seronegative, 2/60 T4 counts have been <500 and none have developed AIDS.

Such findings may offer avenues of approach of therapy of HIV infected H and a better understanding of the immune abnormalities such patients exhibit. Patients may remain well with few T4 cells. No reassurance can yet be offered since some will deteriorate, usually after suffering symptoms suggestive of imminent AIDS.

Th.B.P.20 A PROSPECTIVE STUDY OF HIV INFECTION IN CHILDREN WITH HEMOPHILIA

Ali, Kaiser; Tsoukas, C; Card, R; Garvey, D; Growe, G; Kobrinsky, N; Poon, M-C; Rivard, G; Ross, E; Rubin, S; Strawczynski, H; Univ.of Memorial,McGill,Saskatchewan,Toronto,Manitoba,Calgary, Canada.

Objectives: A multicenter study was conducted in Canada between Jan.1,1985 and Jan.1, 1989 to determine the prevalence of HIV infection among hemophiliacs and to monitor their clinical and immune status.
Methods: 98 children were initially enrolled and 89 are currently followed. Physical examinations and immune evaluations including DHS skin testing, T cell subsets, quantitative immunoglobulins, lymphocyte mitogen responses and viral serologic assays were carried out every 6 months.
Results:

	At Entry (1985)		At Last Testing (1988)	
	HIV (-)	HIV (+)	HIV (-)	HIV (+)
	n = 67	n = 22	n = 62	n=27*(*5 patients seroconverted)
T Cell Subsets (mean cells/MM³±S.E.M.)				
CD4	893±86	896±11	1092±73	773±136
CD8	434±44	876±12	415±35	723±84
Clinical HIV Disease				
CDC Gr.II, III		16 (73%)		9 (33%)
CDC Gr.IV		6 (27%)		18 (67%)

Conclusions: Although there were no significant decreases of CD4 cells between the first and last testing date, a significant proportion (67%) of seropositives now have severe HIV disease (CDC Group IV). Thus the rate of progression of HIV disease in children is similar to that of adult hemophiliacs.

Hémophilie : autres virus
Hemophilia: Other Viruses

Th.B.P.21 CONTAMINATION D'UN JEUNE HEMOPHILE PAR LE VIRUS VIH 2

Tricoire Joëlle*, Robert,A*, Puel,J**, Brun-Vésinet,F***, Gayet, C**, Régnier C*
* Pédiatrie B, CHU Purpan, 31059 Toulouse Cédex, France; ** Laboratoire de Virologie, CHU Purpan, 31059 Toulouse Cédex, France; *** Laboratoire de Virologie, Hôpital Cl Bernard, 75000 Paris, France.

objectif. Possibilité de contamination d'un jeune hémophile par le virus VIH 2 en mars 1986 à partir d'une perfusion de facteurs de substitution non chauffés gardés par négligeance.
Méthode. Surveillance régulière clinique et biologique depuis 1984. Les études virologiques comportent un dosage des AC en Elisa, un dépistage en Western-Blot pour VIH 1 et VIH 2 (IgG et IgM), RIPA et culture virale sur lymphocytes pour confirmation.
Résultats. Les différents bilans révèlent une séro-conversion pour le virus VIH 2 en Décembre 1986.
Un an après le contage, il va développer un syndrome lymphadénopathique avec parallèlement une baisse des lymphocytes T4 (600/ml) et une inversion transitoire du rapport $\frac{T4}{T8}$

La confirmation de l'infection par le virus VIH2 a pu être apportée par RIPA et culture sur lymphocytes.
Conclusion. La contamination d'un hémophile par le virus VIH 2 est rare en France. Il n'y a pas de différence dans l'expressivité clinique et biologique entre l'infection par le virus VIH 1 et VIH 2 étant donné qu'ils présentent des caractéristiques communes de lymphotropisme et cytopathogénicité.

Th.B.P.22 PRE-EXISTING CYTOMEGALOVIRUS INFECTION INCREASES THE PROGRESSION TOWARDS AIDS IN A COHORT OF HAEMOPHILIACS.

Webster, A.; Lee, C.; Grundy, J.E.; Emery, V.C.; Kernoff,P.*; Paul D. Griffiths. Depts. of Virology and Haematology*, Royal Free Hospital School of Medicine, London NW3, England.

Objective Does CMV enhance HIV pathogenicity?
Methods IgG antibodies against CMV and against HSV (as a control) were measured by radioimmunoassay. HIV antibody was measured by enzyme immunoassay (Wellcome).
Results The presence of CMV but not HSV antibodies, was associated with the development of AIDS (See Table).

	CMV serostatus		Totals	HSV serostatus		Totals
Symptoms	+	-		+	-	
Yes	18	4	22	14	8	22
No	40	39	79	46	31	77
Totals	58	43	101	60	39	99

Kaplan-Meir plots related to the time of HIV seroconversion showed that CMV positive patients progressed to develop AIDS significantly more rapidly than did CMV negative patients. There was no difference for HSV.
Conclusions These results are consistent with the hypothesis that CMV cooperates in vivo with HIV to enhance the rate at which AIDS develops. Controlled trials of anti-CMV drugs would be warranted in individuals infected with both viruses to see if this cooperation can be suppressed.

Th.B.P.23 HIGH BURDEN OF EPSTEIN-BARR VIRUS IN HIV-INFECTED HEMOPHILIAC PATIENTS.

Sumaya, Ciro; Martinez, R.; Parmley, R.; Drake, J. and Ench, Y. Univ. of Texas Health Science Center, San Antonio, Texas, U.S.A.

Objective. To determine if HIV-infected hemophiliac patients have an excessive burden of Epstein-Barr virus (EBV) that potentially could produce subsequent deleterious complications.
Methods. The patient group consisted of 47 patients with hemophilia (predominantly type A) and an underlying HIV infection (31 asymptomatic, 13 ARC, 3 AIDS) and 7 others lacking the HIV infection. EBV levels were determined by qualitative and quantitative transformation assays while antibody determinations were performed by indirect immunofluorescence.
Results. The asymptomatic, ARC, and AIDS groups of HIV infected hemophiliac patients had a greater prevalence/value of infectious EBV in oropharyngeal secretions (range of 56.5 - 100%), spontaneous proliferation of peripheral blood mononuclear cells (≥40% of specimens), and EBV infected cells (30 [±40.6]) - 203 [±664.6] per 10^7 peripheral blood mononuclear cells) than the non-HIV infected hemophiliac and normal control groups. A variable elevation of EBV antibody responses was found.
Conclusion. HIV-infected hemophiliac patients had as highly an increased burden of EBV in body secretions/fluids and, to a lesser extent, abnormal EBV antibody responses as that previously found in adult HIV-infected homosexual groups. The consequences of the abnormal immunoregulation of EBV in HIV-infected hemophiliacs, ie, development of lymphoproliferative or lymphomatous lesions, needs to be monitored closely.

Th.B.P.24 HTLV-1 IN HEMOPHILIACS IN ARGENTINA

Bouzas,María Belén*;Mathov,I*;Muchinik,G*;Campestri,R*;Pérez Bianco,R*;Vercauteren,G**
*IIHEMA,Academia Nacional de Medicina,Buenos Aires,Argentina,**Institut of Tropical Medicine "Prince Leopold",Antwerpen,Belgium.

Objective. To study the seroprevalence of HTLV-1 antibodies on hemophiliacs.
Methods. Sera previously drawn from 127 hemophiliacs for assessment of HIV-1 incidence (51 -40.2%- HIV-1-pos. and 76 -59.8%- HIV-1-neg.) were studied to determine the impact of HTLV-1. Sera were screened for HTLV-1 antibodies by means of an ELISA assay (CPI). Samples repeatedly positive or undeterminated were tested thru Western Blot.
Results. Only 1 (0.79%) out of 127 was HTLV-1-pos. Western Blot showed bands at p24, p36, gp46, p53. A retrospective study of this patient demonstrated seropositiveness as from 1985. No cross-reaction was observed between HIV-1 and HTLV-1. The HTLV-1-positive serum sample was HIV-1-negative.
Conclusion. No co-infection with HIV-1 and HTLV-1 was found. Our data suggest that in our country HTLV-1-infection among hemophiliacs is very low, although more studies should be performed to ascertain the seroprevalence of this virus on the group.
(Supported by a grant from Fundación Roemmers).

Th.B.P.25 SIGNIFICANCE OF VIRAL SUPERINFECTIONS BY HTLV-I, EBV AND CMV FOR IMMUNOLOGICAL DISORDER IN HIV-INFECTED HEMOPHILIACS

Okubo, S. and Yasunaga, K.
Kansai Medical University, Osaka, Japan.

In order to clarify the influence of viral superinfections by HTLV-I, EBV and CMV for immunological disorder in HIV-infected persons, 55 hemophiliacs were examined. Twenty-two of 55 were seropositive for HIV. Two of 22 were AIDS and 20 were AC. Results: 1. Although more rapid decrease in CD4+ cell count and CD4/8 ratio could be seen in one patient beeing positive for both anti-HIV and anti-HTLV-I antibodies, our two AIDS patients were seronegative for HTLV-I. 2. Irrespective of these viral superinfections, such autoantibodies as RF, LE factor, anti-nuclear ab. and anti-DNA ab. could be found in none of HIV-infected hemophiliacs. Nevertheless, one AC patient with ITP revealed relatively high anti-EB VCA IgG ab. level (X320), though anti-HTLV-I and anti-CMV antibodies were negative. 3. No difference on the frequencies of the positive anti-HTLV-I, EBV or CMV antibody could be seen between patients with and without positive serum HIV Ag. and HIV isolation. Conclusion: No clear immunosuppressive or AIDS-facilitating effects attributable to these viral superinfections could be recognized, though such possibility seemed to be undeniable in some HIV-infected hemophiliacs.

Th.B.P.26 LIVING WITH HIV: A WEEKEND RETREAT FOR TEENAGERS AND YOUNG ADULTS WITH HEMOPHILIA

Martin, Jacqueline*, Lindner, L.* and Neil, J.*
* Hemophilia Assessment Clinic, Vancouver, BC, Canada.

Objectives. A weekend "retreat" was planned to: (1) provide a non-medical setting for socialization among teenagers and young adults with hemophilia. (2) promote discussion about HIV and hemophilia issues, (3) provide accurate information about hemophilia and HIV, (4) discuss issues of sexuality and transmission of HIV, (5) help develop beneficial coping strategies. The team would be able to observe their social and functional capabilities in an informal setting.
Method. Seventeen teenagers and young adults with hemophilia (aged 14-29) spent three days in a resort setting. Educational methods included one to one and group instruction and group discussion. Young adults with hemophilia acted as role models focusing on social and educational concerns and ways of coping. The health team (nurse, social worker and physiotherapist) were able to observe and assess social interaction and functional capabilities throughout the weekend.
Results. Completed evaluations showed that all participants were enthusiastic about the opportunity to meet others with hemophilia, to develop stress management techniques, to learn more about hemophilia and/or HIV and to develop exercise programs related to specific areas of concern. Observations by staff led to better understanding of the needs of these patients.
*Funding for the retreat was provided by the Federal Centre for AIDS, Health and Welfare Canada.

Th.B.P.27 RESPONDING TO THE PALLIATIVE CARE NEEDS OF PERSONS WITH HEMOPHILIA AND AIDS

Mera, Nena M., Shearer, R. J.,
Federal Centre for AIDS, Health and Welfare Canada,
Ottawa, ON, Canada.

Recent surveys and national workshops among comprehensive care centre personnel have indicated the growing concern to give attention to the palliative care needs of persons with hemophilia.

Two surveys conducted in 1988 have shown that 950 of Canada's 2,300 classic hemophilia population have been infected with HIV. 84% of those infected are under 40 years of age. Epidemiological projections indicate that 50% of those who are now infected will have developed AIDS by 1993.

This presentation will show that the infected population is different from other risk groups in that they include all age groups, often include several members of one family, many of the adults are married with children; they all suffer from a pre-existing life-threatening illness (hemophilia); they have very little pre-existing financial security (e.g. life insurance); and they all have access to a pre-existing care program.

The challenges now facing the hemophilia community will be described. How the Canadian Hemophilia Society will respond to the palliative care needs of persons with hemophilia and AIDS (e.g. development of palliative care program components, home care and formal liaison with and adaptation of other palliative care related programs/services) will be presented.

Th.B.P.28 PSYCHOSOCIAL MANAGEMENT OF HIV INFECTION AMONG HEMOPHILIACS IN WESTERN CANADA

McClure, Wilma,* Lindner, L., McDonald, J., Bell, C., Schwetz, N., Akabutu J., et al.* Northern Alberta Comprehensive Hemophilia Centre, Edmonton, Alberta, Canada

Objective: To evaluate the current psychosocial management of HIV infection among hemophiliacs at the five Western Canadian Comprehensive Hemophilia Centres.
Method: All centres submitted a written report on their current approaches to the psychosocial management of HIV infection in hemophiliacs. The reports covered the following areas of clinical activity: education, pre and post test counselling, quiescent phase of HIV infection, counselling of AIDS patients and their families and bereavement counselling.
Results: 508 hemophiliacs are registered with the Western Comprehensive Hemophilia Centres. 85% of patients have Factor VIII deficiency and 15% Factor IX deficiency. 133 or 26% have seroconverted to HIV of which 11% have died. The Centres concurred that the current methods of management are inadequate to deal with the problems posed for hemophiliacs and their families. Thus, poor education about HIV issues, increasing patient anxiety, continuing low self-esteem of infected patients and inappropriate decision making are likely to continue to plague this population.
Conclusion: Structured psychosocial programs with pre-defined objectives are necessary if beneficial outcomes are to be achieved for this population of patients.

Th.B.P.29 AIDS AND HEMOPHILIA: CREATING UNIQUE FAMILY DYNAMICS

Roy, M.S.W., Charles M., Montreal Children's Hospital, Social Service Department, Montreal, Quebec, Canada

Hemophilia is a hereditary blood clotting disorder usually passed on from mother to son. The genetic aspect of hemophilia creates family dynamics unique within the AIDS community.

HIV was acquired:

1) as a result of medical treatment for hemophilia. Families where HIV and hemophilia are present are faced with the dilemma of mistrusting the medical team they are dependent on for treatment;
2) because of an inherited condition. Anger and guilt are compound dynamics within these family systems;
3) and is found throughout the extended family;
4) by children with hemophilia therefore, parents are faced with the responsibility of telling them of their HIV infection;
5) by the brothers of women who are known carriers of the hemophilia gene. Sisters of hemophiliacs with HIV/AIDS are giving serious consideration to having children. They live in fear of what unknown catastrophic illness will next infect the hemophilia community.

The author will discuss these five clinical issues specific to families where hemophilia and HIV/AIDS are present and make treatment recommendations for social work professionals.

Th.B.P.30 CONDOM USAGE REPORTED BY FEMALE SEXUAL PARTNERS OF ASYMPTOMATIC HIV SEROPOSITIVE HEMOPHILIC MEN

Price, William*; Merigan, T.**; Peterman, T.***
*Research Triangle Institute, Research Triangle Park, NC, U.S.A.
**Stanford University, Stanford, CA, U.S.A.
***Centers for Disease Control, Atlanta, GA, U.S.A.

Objective. To report condom usage rates among a sample of female sexual partners of HIV seropositive hemophilic males.
Method. ACTG 036 is a placebo-controlled clinical trial of Zidovudine (ZDV) in HIV seropositive hemophilic men. Female sexual partners of these men are being enrolled in a prospective study of the efficacy of ZDV in preventing male-to-female transmission of HIV. Behavior and HIV serostatus of these seronegative women will be evaluated at entry and when their partners complete study therapy with ZDV or placebo. The women enrolled are not receiving ZDV.
Results.

	Percent Condom Usage Reported							Not Sexually Active	Total
	100	99	90	80	50	10	0		
Number of respondents:	10	3	1	1	1	1	4	4	25

Twenty-five women have thus far (January, 1989) been enrolled; mean age at enrollment was 35.1 years (range 25 to 56). Reasons for not using condoms were not surveyed. 7(28%) reported children of ages 2 to 6 years, indicating previous high risk for exposure to HIV.
Conclusion. Only 47.6% (10/21) of sexually active female partners of HIV seropositive hemophilic males reported condom usage at 100%, despite awareness of male serostatus and risk reduction counseling.

Th.B.P.31

PSYCHOSOCIAL AND NEUROPSYCHOLOGICAL STATUS OF HAEMOPHILIACS AND GAY MEN WITH HIV INFECTION : A CONTROLLED INVESTIGATION.

Catalan, Jose**, Klimes, I.*, Bond, A.**, Garrod, A.**, Day, A.**, and Rizza, C.***
*Dept.Clinical Psychology and **Oxford University Dept.Psychiatry, Warneford Hospital, Oxford, and *** Oxford Haemophilia Centre, Oxford, U.K.

Objective. To establish prevalence of psychosocial and neuropsychological problems in HIV+ subjects; to compare the two transmission groups; to identify the characteristics of those with problems.
Methods. HIV+ haemophiliacs (n=36) and HIV- haemophiliac controls (n=36)and HIV+ gays (n=20) and HIV- gay controls (n=25) were studied. Measures included psychiatric state (PSE, POMS, Hopelessness); coping (Hardiness, locus of control); social and sexual adjustment; neuropsychological screen (Trails A and B, digit symbol, verbal fluency).
Results. In both transmission groups HIV+ individuals had higher levels of psychological symptoms and hopelessness than HIV-. Irrespective of HIV status gay men had higher levels of psychosocial problems than haemophiliacs, and this difference was especially marked in the case of negative individuals where it was found that gay men had much higher levels of psychosocial problems than negative haemophiliacs. No differences were found between groups on neuropsychological measures.
Conclusions. HIV infection appears to be associated with psychosocial problems irrespective of transmission category. Asymptomatic individuals do not show neuropsychological impairment. Gay men (whatever their HIV status) seem more likely to experience psychological problems. The therapy implications of this finding need to be considered.

Th.B.P.32

RISK FACTORS FOR PSYCHIATRIC DISTRESS AMONG HEMOPHILIACS INFECTED WITH HIV1

Dew, Mary Amanda*; Ragni, M.*,**; and Nimorwicz, P.**
University of Pittsburgh, Pittsburgh, PA, USA, **Hemophilia Center of Western Pennsylvania, Pittsburgh, PA, USA.

Objectives. To examine psychiatric correlates of HIV1 infection in a major risk group for AIDS; to identify psychosocial characteristics of HIV1+ men that increase their risk for psychiatric distress following infection.
Methods. All moderate/severe hemophiliacs residing in western Pennsylvania, USA, plus mild hemophiliacs known to the regional Hemophilia Center, were contacted. Seventy-five men (73% of the population) were interviewed and their medical records were reviewed: 31 were HIV1+ and 44 were HIV1-.
Results. HIV1+ men had significantly higher SCL-90 symptom scores than HIV1- men, particularly in depression and anxiety areas. There were no differences among HIV1+ men according to infection stage or clinical severity of hemophilia. Seven psychosocial factors exacerbated the effects of infection on mental health: family psychiatric history, low social support from wife, low family support, low friend support, a poor sense of personal efficacy, perceiving high daily stress related to HIV1, and experiencing recent life events involving loss. HIV1+ men with one or more such characteristics were highly symptomatic; remaining HIV1+ men had lower symptom levels similar to all HIV1- men. The likelihood that HIV1+ men would experience clinically significant distress accelerated when multiple factors were present.
Conclusion. These data suggest that clinical services to alleviate distress in infected populations should be targeted to intervene on these psychosocial assets and liabilities that individuals bring to the situation.

Th.B.P.33

PREDICTION OF SAFER SEX PRACTICE AND PSYCHOSOCIAL DISTRESS IN ADULTS WITH HEMOPHILIA AT RISK FOR AIDS

Parish, Kathy L.*, Mandel, J.**, Thomas, J.*, and Gomperts, E.* *Childrens Hospital of Los Angeles, ** University of California San Francisco, San Francisco, CA, U.S.A.

Objective. To determine which behavioral factors are predictive of consistent condom use and psychosocial distress in hemophilic adults at risk for AIDS.
Methods. A self-administered questionnaire was sent to all 975 identified persons with hemophilia in California in 1987-88. Items were designed to identify factors associated with decreasing transmission of HIV to partners and with psychosocial distress levels indicative of need for intervention.
Results. Analyses of data from 351 respondents indicate that only one-third report consistent condom use during vaginal intercourse. Predictors to consistent condom use were discussion of safer sex with partner, knowledge of HIV test results, and postponement of childbearing; these factors produced a cumulative R^2 of .44. 24% of respondents indicated experiencing significant distress. Predictors to psychosocial distress were worrying about transmitting HIV, perceived chance of developing AIDS oneself, recreational drug use, and knowledge of HIV test results, again with a cumulative R^2 of .44.
Conclusion. Awareness of HIV+ sero-status appears to be linked both to safer sex practice and psychosocial distress, emphasizing the need for ongoing support to these individuals and their families. Couple communication and perceived risk of AIDS for self and others are key factors in coping with AIDS. A better understanding of the impact of the AIDS threat on partners and couple functioning, in order to facilitate communication and shared responsibility for risk reduction in couples, is needed.

Th.B.P.34

GUIDELINES FOR DEALING WITH PREGNANCY IN SEROPOSITIVE HEMOPHILIACS AND THEIR SPOUSES

Kraus, Elissa; Forsberg, A. and Brettler, D.
New England Hemophilia Center, Worcester Memorial Hospital, Worcester, Massachusetts, U.S.A.

Objective. To describe a protocol for HIV testing in pregnancies of seropositive hemophiliacs and their spouses.
Methods. All patients followed at the New England Hemophilia Center receive counselling concerning HIV transmission. "Safe sex" practices and avoidance of pregnancy is strongly advocated. However, pregnancies among seropositive hemophiliac males and their spouses have occurred. Since 1985, a protocol for testing wives insisting on pregnancy has been instituted. The wife is tested every 2-3 mos. until conception, condom use is recommended except at time of ovulation. HIV Ab testing is performed at 6 to 8 and 12 to 16 wks. gestation (so that termination is an option if seroconversion occurs), and at 8 mos.
Results. Since 1985, 13 pregnancies have occurred in 9 couples with a seropositive hemophiliac. Eight pregnancies were monitored according to our protocol, and all wives were seronegative. There were 3 full term pregnancies (children alive and well at ages 4 mos. to 2 1/2 yrs.), 2 were miscarriages and 3 are ongoing (2 at 3 mos. gestation, 1 at 6 mos. gestation). Two pregnancies have been monitored without our protocol, one completed and one ongoing at 5 mos. gestation. At 8 wks. gestation of the first pregnancy the wife was found to be seropositive. The couple elected to continue the pregnancy after intensive counselling. The baby was seropositive at birth and died of AIDS at age 11 mos. In the 3 pregnancies that occurred without any HIV testing, the children are alive and well at 1 1/2 yrs. to 3 yrs.
Conclusion. Despite efforts to inform seropositive patients and their wives of the risks of HIV transmission, some will choose to become pregnant. HIV testing during the pregnancy will allow the couple to make informed decisions about the pregnancy should seroconversion occur.

Th.B.P.35

A TEAM RESPONSE TO HIV/AIDS CARE IN PERSONS WITH HEMOPHILIA

Nena Hera, M.Sc.S.W., C.S.W., Robert O'Niell*
Social Services Advisor, Federal Centre for AIDS, Health and Welfare Canada, Ottawa, Canada *Canadian Hemophilia Society

This presentation will describe how interdisciplinary "dialogue days" was used as an approach to team building in introducing HIV/AIDS care in Canadian Hemophilia Care Centres.

Dialogue days conducted in 1987 and 1988 involved hemotologists, nurses, coordinators, social workers and psychologists. The different health care professionals identified dimensions of HIV/AIDS care needs in the hemophilia community, shared information, re-examined roles and recognized important linkages.

The extended "results" of these dialogue days will be presented at this conference. The results will demonstrate how interprofessional "dialogue days" can be a critical step in redefining the roles of various health care team members in response to a new health care situation.

Th.B.P.36

TUBERCULOSIS IN AIDS PATIENTS IN RIO GRANDE DO SUL: A NEW EPIDEMIC?

Sprinz, Eduardo, Kronfeld, M.
Hospital de Clinicas de Porto Alegre, Rio Grande do Sul, Brasil.
Universidade Federal, Porto Alegre, Rio Grande do Sul, Brasil.

Objective: Establish the incidence and the most common sites affected by Mycobacterium tuberculosis in AIDS patients in Rio Grande do Sul (RS) state.
Methods: It was reviewed, at random, 50 AIDS inpatients at Hospital de Clinicas de Porto Alegre between July and December 1988. It was considered positive if the culture, from any site, "in vivo" or "post-mortem", identified Koch bacilli.
Results: In 20 patients (40%) Koch bacilli was present. 25% (N=5) were at three or more sites (mainly lungs, bones, lymph nodes and gastrointestinal tract); 25% (N=5), at gastrointestinal tract; 20% (N=4), in lungs; 20% (N=4), in lymph nodes; 1, in pericardium and the other with lung and joint involvement.
Conclusion: These are expressive numbers. First, it is one of the highest incidence of tuberculosis in the world. Second, the site of involvement does not seem to influence the mortality of the group. Last, it is very import- and to consider the presence of Koch bacilli in AIDS patients coming from RS state.

Th.B.P.37

Th.B.P.38

THORACIC RADIOGRAFIC ASPECTS OF TUBERCULOSIS IN AIDS

Yamashita,HK*;Accetturi,CA**;Ribeiro,SA***;Stávale , JN**** and Kambara,AM* .*Departement of Imaging Diagnostic**Division of Infectious Disease***Health Center****Departement of Pathology-ESCOLA PAULISTA DE MEDICINA-São Paulo-Brazil.

The authors present an evaluation of thoracic X-rays in patients with AIDS and tuberculosis,its value for the diagnostic and therapeutic orientation.

Patients were clinically classified according to CDC (centers of Disease Control),of USA,being 25 men and 2 women ,aged between 18 and 66 year,16 homosexuals,5 bisexuals,2 users of intravenousdrugs and 3 undeterminated.All cases with positivie ELISA . The diagnostic of the Mycobacterium tuberculosis was comproved by analyses of sputum(6 cases),bronchial washing(1 case) , endoscopic biopsy(1 case),pleural biopsy(1 case),necropsy(9 cases) and therapeutic trial(5 cases).Others 4 cases had comproved disease by ganglion biopsy(3 cases) and liquor(1 case).

Lesions more frequently found were adenomegaly,in 20 cases and nodular lesions,less than 5mm,in 17 cases.The association between nodular and adenomegaly were the most significant.

Patients with correct diagnostic and treatment showed partial or total resolution of the thoracic lesions(16 cases). Later diagnostic or untreated patients had not good prognostics.

Association of thoracic lesions and therapeutic trials can give us the diagnostic of the tuberculosis as showed in 4 patients treated wich died,with proven diseases in autopsies.

Th.B.P.39

GASTROINTESTINAL TUBERCULOSIS IN AIDS PATIENTS: THE RIO GRANDE DO SUL EXPERIENCE

Sprinz, Eduardo; Kronfeld, F.
Hospital de Clinicas de Porto Alegre, Rio Grande do Sul, Brasil.
Universidade Federal do Rio Grande do Sul, Brasil.

Objective. Study the incidence of gastrointestinal tuberculosis and its relation with diarrhea in Rio Grande do Sul(RS)state.
Methods. The registers of 50 AIDS inpatients at HCPA between July and december 1988 were reviewed(8 were excluded, as they did not have diarrhea.
Results. From the remaining 42 cases, in 9(21,4%) cultures obtained from stools(N=7) or gastrointestinal biopsy at necropsy(N=2) yielded Mycobacterium tuberculosis. In all 7 cases the diarrhea improved with the use of anti-tuberculous drugs.
Conclusion. Our findings support the importance of gastrointestinal tuberculosis as a common treatable cause of diarrhea in patients with AIDS.

Th.B.P.40

TUBERCULOSIS AND AIDS

Biancalana, Maria Lucia Neves; Mendes M.S., Rodrigues G.A., Stefani, H.N., Levi G.C., Mendonça J.S.
Department of Infecctious Diseases - Hospital do Servidor Publico Estadual - São Paulo - Brazil.

Between 1985 and 1988 we studied 19 patients with positive anti-HIV scrologic test and tuberculosis diagnosticated by positive culture for M. tuberculosis. Tuberculosis was the first manifestation of HIV related infections in 12 patients; concomitant with other HIV related conditions in four cases (two Kaposi sarcoma); three patients had presented an opportunistic infection previously. M. tuberculosis was cultured from sputum in 11 patients, lymphonode in three, liver two, lung one, urine one and gastric lavage one. CD4 + count was performed in all patients but three and was low in all cases with a median count of 154 cells/mm³ (range 17 to 378), CD4 + count was above 200 in five patients (group A) and lower than 200 in 11 cases (group B). Group A had two patients with pulmonary tuberculosis, two with disseminated tuberculosis and one with ganglionar tuberculosis. Group B had eight patients with disseminated tuberculosis, two with pulmonary tuberculosis and one with renal tuberculosis. Seven of 14 (50%) patientes treated with RMP, INH and PZA had hepatitis during the first two weeks of treatment. There was total normalization in all cases after change to EBT and SM. Further reintroduction of INH 6 cases was well tolerated. The authors call attention to the low CD4 + counts in all cases, not related to the clinical form of tuberculosis. They also observe that hepatitis was very frequent, early and probably not related to INH.

Th.B.P.41

DRUG-RESISTANT TUBERCULOSIS IN AIDS AND ARC

Pablos-Mendez A, Raviglione M C, Battan R C
Department of Medicine, Cabrini Medical Center, NYC, N.Y., USA

Objective: Tuberculosis (TB) is now frequently reported in AIDS, and its proper treatment remains to be determined. We reviewed the prevalence of drug-resistant Mycobacterium tuberculosis in patients with AIDS or ARC.

Methods: We searched our mycobacteriology registry for all cases of TB from 1982 to 1988. Of 137 patients, 13 had AIDS or ARC: their clinical records were reviewed.

Results: There were 11 men and 2 women (mean age 38); 6 were Hispenic, 3 black, 3 white and 1 Asian. Risk factors were: homo/bisexuality in 7, intravenous drug abuse in 4, heterosexual contact in 1, and unknown in 1. Two patients had ARC, 11 AIDS. Five patients had a history of TB. M. tuberculosis was isolated from lungs (11), blood (2), bone marrow (2), CSF (1), lymph node (1). Chest X-ray showed apical lesions with or without cavitation in 4 patients, and diffuse interstitial infiltrates in 6. In only 5 patients was TB only and alone in the lungs. Most patients initially received 3 drugs and improved; two died of other AIDS-related diseases. Resistance to either INH, RMP, EMB or SM was present in 3 cases (0.23 versus 0.13 in our total TB population), and in 2 of them (homeless) to both INH and RMP.

Conclusions: Atypical manifestations of TB were common in our patients with AIDS or ARC. Resistance was seen in 3 cases; in 2 of them to 2 drugs, but these patients were homeless and drug-resistant TB may be expected. Thus, AIDS/ARC per se is not associated with increased drug-resistant TB, and an initial 2-drug regimen is probably sufficient.

Th.B.P.42

MYCOBACTERIUM KANSASII (MK) INFECTION IN HIV INFECTED PATIENTS: A 5 YEAR REVIEW

Cardona, L.*; Valainis, Gregory*; and Greer, D.**.
*Tulane University Medical Center, **LSU Medical Center, New Orleans, LA, USA.

Objective. A significant increase in the number of isolates of (MK) associated with HIV infected patients has been observed. We reviewed all patients (PTS) with + MK cultures identified at our mycobacteriology reference laboratory.
Methods. A retrospective review of all PTS with a + culture between 1983-88 was performed. Clinical presentations, radiographic findings, therapy, and outcome were reviewed to identify MK disease with an emphasis on HIV PTS.
Results. MK was cultured 205 times from 72 PTS over a 60 month period; 23(32%) were HIV coinfected. Of these 21 had AIDS and 2 had ARC with the first isolation. An increasing % of isolates were from HIV PTS (zero in 1983 to 50% by 1987-88). Respiratory isolates were the main source of + cultures (90.3%), yet only HIV PTS manifested dissemination (liver, stool, bone marrow, blood) with 1 exception. Most had high level INH (>1.0 ug) resistance (60%). The clinical presentations were nonspecific. Fever, weight loss, cough, and night sweats were seen in 90%. The chest radiographic findings (63.2% pneumonitis, 0% cavitation) as well as the frequent coexistence of PCP (82%) made it difficult to identify true MK disease in this population. Nineteen (82.6%) PTS expired within 30 months of isolation.
Conclusion. The isolation of MK from HIV infected PTS may contribute to their overall morbidity and mortality. Distinguishing disease from colonization is difficult using currently accepted criteria.

Th.B.P.43 TUBERCULOSIS IN HIV PATIENTS : CORRELATION BETWEEN NATURAL HISTORY, CLINICAL PRESENTATION AND IMMUNOLOGICAL STATUS

Gérard, M.; De Wit Stéphane; Sommereijns, B.; Clumeck, N.
Division of Infectious Diseases, St Pierre University Hospital, Brussels, Belgium.

Tuberculosis (TB) associated with HIV infection is classified as TB of lungs and/or lymph nodes (LTB - CDC group IV C2) or disseminated TB (DTB - CDC group IV C1; AIDS). In order to assess the clinical and immunological relevance of considering both entities separately we studied 31 cases of TB (20 DTB, 11 LTB) diagnosed among 686 HIV patients (P). Median CD4 cell count at the time of TB diagnosis, occurence of opportunistic infections (OI) or Kaposi's sarcoma (KS) and survival were evaluated. Median CD4 cell count was low (73/mm3 - range: 3-657) and similar in both DTB and LTB (82/mm3 versus 76/mm3 p: NS). OI or KS were found to occur before or concomitantly to TB in 7/20 P with DTB and 5/11 P with LTB (p: NS). Occurence of first diagnosis of OI or KS after diagnosis of TB was also similar in both groups (4/18 P with DTB vs 2/11 P with LTB - p: NS). When TB occured as a first infection, 7 of 18 evaluable P with DTB and 4 of 11 evaluable P with LTB (38% vs 36% - p: NS) remained free of OI or KS for a median follow up period of 12 months. Probability of survival 10 months after TB diagnosis was similar for DTB and LTB (0.8 vs 0.6 - p: NS).
This study suggests that disseminated tuberculosis in HIV P is not significantly linked to a more profound immunological impairment or a worse prognosis than TB limited to lungs or lymph nodes. Relevence of considering both entities separately should be reassessed.

Th.B.P.44 SURVEILLANCE FOR HIV/AIDS-RELATED TUBERCULOSIS (TB) IN THE UNITED STATES (U.S.)

Ciesielski, Carol, Buehler J, Bloch A., Berkelman R.
Centers for Disease Control, Atlanta, GA, USA

Objectives: To assess the magnitude and distribution of HIV/AIDS-related TB morbidity and mortality in the U.S.
Methods: To describe TB and AIDS morbidity, State and local health departments match TB cases to AIDS cases diagnosed within the preceding 3 years. To describe TB and HIV/AIDS mortality, we used national vital statistics for 1980-86 and focused on men 25-44 years of age.
Results: Of the 32,490 patients with AIDS reported in 1981-87 and 122,756 TB cases reported in 1978-87 from 44 States, 1 Territory, and 10 local jurisdictions, 1,197 persons appearing on both registers have been identified to date, accounting for 3.7% of AIDS cases and 1.0% of TB cases nationwide. The areas with the highest percentage of AIDS cases with TB are Florida (8.4%), Connecticut (6.6%), New York City (5.3%), and Houston (5.2%), although cases have been found in all regions. From 1980 to 1986, TB mortality rates (underlying cause) increased from 0.23 to 0.41 deaths/100,000 men 25-44 years (71 to 155 deaths) for the U.S. and from 0.32 to 0.88 in 5 States with the highest AIDS incidence (26 to 89 deaths--66 of which also had a diagnosis of immune deficiency, Kaposi's sarcoma, or *Pneumocystis carinii* pneumonia). In contrast, TB mortality declined (0.19 to 0.06/100,000) in States with the lowest AIDS incidence.
Conclusion: TB is an important cause of morbidity in AIDS patients. The HIV epidemic is probably a leading reason for recent increases in TB in young adults and is contributing to TB mortality in some areas.

Th.B.P.45 INCIDENCE,DIAGNOSIS AND TREATMENT OF MYCOBACTERIOSIS IN AIDS

Heise,Walter,Skörde,J.,Nehm,K.,Arasteh,K.,Habermann,R., L'age,M.
Auguste-Viktoria-Hospital,Berlin,West Germany
II. Internal Department,LMUA

Objective: To describe the main microbiological and clinical aspects and the incidence of mycobacteriosis in 33o HIV patients.
Methods: Different specimen(blood,urine,broncoalveolar lavage,sputum,bone marrow,spinal fluid,stool,biopsies) were examined for mycobacteria microscopically and culturally.Clinical symptoms like fever,diarrhea or weight loss were related to positive bacteria findings.
Results: Mycobacteria were isolated in 7o/33o (21,2%) HIV patients.In 14 cases with M.tuberculosis most of the patients presented with pulmonary or gastrointestinal symptoms.Dissemination was found in 7 cases. Non-tuberculosis mycobacteria were found in 56 patients (51x MAI,3x M.kansasii, 2x M. gordonae,1x M.fortuitum)whereas 8o% of these patients presented mainly with fever and weight loss.Colonization was found more often(3ox BAL or sputum,14x gastrointestinal tract) than dissemination (14x blood,1x liver,1x bone marrow,3x lymph node).Therapy for non-tuberculosis mycobacteria(ansamycin,clofazimine,ethambutol,ciprofloxacin) was reported in one third of the cases.
Conclusion: The incidence of mycobacteriosis in AIDS is high reaching 21,2% in our clinic. 8o% of these are due to non-tuberculosis mycobacteria. Clinical symptoms are not specific,fever and weight loss are a common finding in MAI infection.Therapy may be succesful even in atypical mycobacteria.

Th.B.P.46 EVIDENCE OF ANOTHER EPIDEMIC: Tuberculosis and HIV in a NYC Community Hospital.

Marie Ciacco, MPH; D. Spicehandler, MD
St. Clare's Hospital and Health Center, New York, NY USA

Objective: To analyze the recent rise of *Mycobacterium tuberculosis* (MTB) infection and disease in a NYC community hospital.
Methods: Review of MTB data from epidemiology files of 1984 - 1988. Retrospective analysis of data from patient and personnel health medical records.
Results: This 250 bed hosptal, with a 75 bed dedicated AIDS Unit, is experiencing a surge in the incidence of MTB disease. The hospital's annual caseload of MTB patients has grown from 20 in 1985 to 155 in 1988. Further analysis reveals a classic epidemic curve in 1988 case reports. To date, 52(33%) are culture confirmed. Cases are associated with one or more known risk factors; homelessness, incarceration, HIV infection and reactivation. However, 13/52 (25%) had no evidence of HIV infection. Concurrently, a rise in the number of personnel exposures to undiagnosed patients and an increase in utilization of single rooms for acute pulmonary TB also occured. PPD skin test conversions among staff members increased from 5 (1986) to 12 (1987) to 19 in the first half of 1988. 1/5 (20%) conversions in 1986 as compared to 9/19 (42%) in 1988 occured in non patient care workers. There were no clinical cases of MTB among staff.
Conclusion: PPD conversion among hospital staff demonstrates a spread of this agent in both the community and the hospital. In most cases, clinical disease remains confined to high risk individuals. However, this hospital's increase in clinical cases suggests that the rise in MTB among HIV+ individuals is impacting on the general community. Early, aggresive community screening and treatment procedures must be instituted to control this epidemic.

Th.B.P.47 INFLUENCE OF GEOGRAPHIC DISTRIBUTION ON ATYPICAL MYCOBACTERIOSIS AND ISOSPORA BELLI IN RIO GRANDE DO SUL(BRASIL)

Kronfeld, Matias; Sprinz, E.
Universidade Federal do Rio Grande do Sul
Hospital de Clinicas de Porto Alegre(HCPA)

Objective. Show that in Rio Grande do Sul(RS) state atypical mycobacteriosis and Isospora belli are not frequent
Methods. Were reviewed 140 registers of AIDS inpatients at HCPA between june 1986 and november 1988 for the occurence of atypical mycobacteriosis or Isospora belli infections.
Results. It was found a possible case of Mycobacterium marinum(it has been successfully treated with tetracycline) coming from Santa Caterine state and 3 gastrointestinal I.belli infections(2 coming from Rio de Janeiro and 1 from New York).
Conclusion. When treting AIDS patients coming from RS, one must hardly consider I.belli or an atypical mycobacteriosis as probable pathogens.

Th.B.P.48 FACTORS INFLUENCING MORTALITY IN DISSEMINATED M. AVIUM (MAI) INFECTION IN ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS) :

S. Sathe, I. Kaminski, R. Kapila, P. Kloser, L. Reichman;
UMDNJ-New Jersey Medical School, Newark, New Jersey. USA

Disseminated MAI in patients with AIDS is a common opportunistic infection (OI) and is unresponsive to therapy; yet its effect on the duration of survival is controversial. 54 patients with AIDS and MAI (Group I) and 23 patients without mycobacterial disease (Group II) were studied. The two groups were similar in demographic, nutritional assessments and HIV, risk factors, but differed with respect to hematocrit (HCT) and total lymphocyte count (TLC); Group I; HCT=22.7 (± 9.4), TLC=573 (± 45.4); Group II; HCT= 31.44 (± 11.3), TLC= 883 (± 74) p <0.001. (± SEM given in parenthesis). Regression analysis showed that these two factors and history of other O.I. were the only factors that related to survival (r = 0.68, p <0.05). Other indices of bone marrow function or treatment did not influence survival. Duration of survival decreased sharply in MAI patients with preceding O.I..

	AIDS (Group II)	MAI without O.I.	MAI with O.I.
Days (Survival)	275	290	140 (p <0.001)
TLC	883	690	443 (p <0.01)

Conclusion: MAI shortens survival in AIDS if it occurs late in the course of disease, if it is preceded by O.I. and if it is accompanied by significant anemia.

Th.B.P.49 MYCOBACTERIUM KANSASII INFECTION IN 15 PATIENTS WITH CLASS IV HIV INFECTION: CLINICAL AND MYCOBACTERIOLOGIC FEATURES

Blair S.*, Muller, K.*; Kocka F.**, Muthuswamy P.*;
Renslow Sherer, M.D. *, et. al
* Department of Medicine, ** Department of Laboratories, Cook County Hospital, Chicago, U.S.A.

Objective: To evaluate the clinical and mycobacteriologic features of M. kansasii infection in the presence of Class IV HIV infection.
Methods: All patients with M. kansasii infection between 10/83 and 11/88 were cross-referenced with all persons with Class IV HIV infection, and a retrospective chart review was conducted, including clinical, radiographic, immunologic, and mycobacteriologic data assessment.
Results: Of 40 patients with M. kansasii, 15 (37.5%) had Class IV HIV infection; of these, 11 (73.3%) were black and 4 (26.7%) white. One (6.6%) was a woman, and 14 (93.4%) men. 10 (66.6%) were gay/bisexual men, 2 (13.3%) IVDU, and 3 (20%) other risk behaviors. 11 (73.3%) had AIDS and 4 (26.7%) had Class IV HIV infection. 11 (73.3%) were diagnosed by sputum evaluation and 4 (26.7%) by bronchoscopy and sputum. 12 (80%) patients had pulmonary disease. 6 (40%) had disseminated disease, of which all were gastrointestinal, 1 bone marrow, and 1 skin. Radiographically, 1 (6.7%) had cavitary disease, and 14 (93.3%) local alveolar or interstitial disease. In 9 patients, the mean T4 cell count was 96/ml. Sensitivity studies revealed resistance to PZA in 3 of 4 isolates and partial resistance to INH in 3 of 4 isolates. Satisfactory clinical responses were observed in 8 of 11 (72.7%) of patients with pulmonary disease only, and in none of the patients with disseminated disease.
Conclusions: M. kansasii infection is common in HIV infection in an endemic area. Dissemination is more common in later stages with advanced immunodeficiency. Upper lobe cavitary disease is uncommon; alveolar and interstitial infiltrates are common. Dissemination to GI tract, skin, and bone marrow occurs. Treatment may be successful in early stages. Resistance to PZA and INH occurs; alternatives for empiric treatment are necessary.

Th.B.P.50 SEROPREVALENCE OF HIV INFECTION IN 183 CONSECUTIVE PATIENTS WITH TUBERCULOSIS (TB) AT A NEW YORK CITY HOSPITAL

Shafer, Robert W; Chirgwin,KD; Glatt,AE; Dahdouh,MA; Landesman,SH; SUNY-Health Science Center at Brooklyn, N.Y., U.S.A.

Objectives: 1)Determine the prevalence of HIV infection in pts with TB. 2)Determine the extent of immunosuppression in HIV infected pts with TB.
Methods: Between 10/87-6/88, all hospitalized adults with newly diagnosed, culture-proven TB, were offered HIV testing and T4 lymphocyte levels.
Results: 70(38%) were intravenous drug users(IVDU), 20(11%) were Haitian, 11(6%) were homosexual, and 82(45%) denied risk factors(RF)(except possible heterosexual contact). 74/80(93%) evaluable pts with RF were HIV infected (AIDS-14, oral candida(OC)-28, +HIV serology-32); 21 pts with RF were not evaluable due to refusal to undergo HIV testing(13), death or discharge prior to diagnosis(8). 8/54(15%) evaluable pts without RF were HIV infected(AIDS-2, OC-1, +HIV serology-5); 28 were not evaluable due to refusal(15), death or discharge(11), equivocal serology(2). Extrapulmonary TB(EPTB) was present in 33/82(40%) HIV infected pts and in 14/52(27%) HIV- pts(p=NS). Disseminated TB (+blood, marrow, or liver culture, or +cultures from 2 extrapulmonary sites) was present in 21/82(26%) HIV infected pts and in 2/52(4%) HIV- pts(p=.003). Median T4 of pts with +HIV serology (without AIDS or OC) was 207(range:23-677); median T4 of HIV- pts was 613(range:238-1614). Median T4 of HIV+ pts with pulmonary TB(241) was similar to median T4 of HIV+ pts with local EPTB (303)(p=NS) but not to median T4 of HIV+ pts with disseminated TB(70)(p=.01).
Conclusions: TB was often the first illness experienced by HIV infected pts. TB in IVDU, Haitians, and homosexuals was frequently associated with HIV infection. TB in pts without RF was also associated with HIV infection. Most HIV+ pts with TB had marked T4 lymphocyte depletion.

Th.B.P.51 TUBERCULOSIS AS PULMONARY COMPLICATION AIDS - ASSOCIATED

Piersantelli Nicolò, Guida B. Dpt.Inf.Dis.Galliera Hosp. Genoa, Italy

Objective. To study pulmonary Mycobacterium tuberculosis (Mt) infection in AIDS patients (pts). Methods. In 42 cases of AIDS from june 86 to june 88 we observed 10 male pts affected by pulmonary tuberculosis: they were heroin-addicts aging from 28 to 40. Results. Bacteriological tests were positive for Mt in sputum (3 cases), in b.a.l. (4), in pleural (1) and in gastric fluid (2). The X-ray and CT examinations have shown an high frequency of medium and/or basal pulmonary infiltrates (8pts) and only one pulmonary cavitation. Only the last developed PPD positive. In 9/10 of the pts the 67-Ga scintigraphy proved the mediastinum involvement. The recovery occourred in 8/10 of the pts, they had X-ray modification in 60 days and bacteriological negativization in nearly 35 days. Conclusion. -In our country,at the opposite of USA, tuberculosis is often a pulmonary complication (23%) even if it isn't diagnostic for AIDS;- their X-ray patterns are topographically unusuals;- the diagnosis may be complicated by the coexisting other opportunistic infections;- the long-term therapeutic response is satisfactory in spite of immunodeficiency;- the high frequency of pulmonary tuberculosis suggest opportunity anti-Mt prophylaxis in early stages of HIV infection in narcotic-addicts.

Th.B.P.52 TUBERCULOSIS IN HIV-INFECTED INDIVIDUALS IN THE PROVINCE OF BRITISH COLUMBIA (1983-1988).*

Blackie Steve, Vedal S, Lawson LM, Ruedy J and Montaner JSG. AIDS Research Programme, St. Paul's Hospital; Respiratory Division, UBC and Division of TB Control, Ministry of Health, Vancouver, BC, Canada.

OBJECTIVE. To describe the clinical presentation, laboratory findings and outcomes of all cases of tuberculosis (TB) in HIV infected individuals diagnosed in the province of British Columbia over the 6 year period ending December 31, 1988.
METHODS. Cases of TB in HIV infected individuals were identified by a linkage between the provincial TB laboratory and the provincial AIDS Surveillance Registry. Medical records of all of the identified cases were retrospectively reviewed.
RESULTS. Fifteen cases were identified. None had AIDS at presentation. Systemic symptoms were present in 13/15 (87%). Respiratory symptoms were common (cough 50%, shortness of breath 50%). Diarrhea was present in 40%. Mean helper count and H/S ratio were already low at diagnosis (90 and .31 respectively). LDH was normal in all cases. Specimens from 51 sites in 15 patients revealed 21 smears (41%) and 32 cultures (62%) were positive. Sputum available in 10 patients was smear positive in 5 (50%) and culture positive in 8 (80%). Stool specimens available in 5 patients were culture positive in 2 (40%) where mucosal biopsy (rectum and small bowel) was also positive. CXR abnormalities were uncommon except for mediastinal adenopathy. All patients were treated with INH, RMP for 12 months + PZA or EMB for the initial 2 months. Except for 2 patients dying shortly after diagnosis from overwhelming disease, clinical response was apparent within the first week of therapy. No relapses or failures of treatment were seen. Eight of 13 survivors developed opportunistic infections (OI) diagnostic of AIDS within 8 months, 6 of these were PCP.
CONCLUSIONS. TB in HIV-infected individuals presented most commonly as disseminated disease. Systemic symptoms were common. However, respiratory symptoms were also prominent and frequently provided a source for diagnosis. Lymph node involvement and gastrointestinal complaints, when clinically apparent, provided an excellent source of diagnostic material. TB appeared to occur as a relatively late event in the course of HIV infection as demonstrated by an already low helper count and the rapid progression to OI.

* Supported in part by the National Health Research Development Programme (NHRDP), Health & Welfare, Canada.

Th.B.P.53 FEVER, WEIGHT LOSS, ANEMIA, SPLENOMEGALY AND ABDOMINAL LYMPHADENOPATHY ARE HIGHLY PREDICTIVE OF DISSEMINATED MYCOBACTERIOSIS IN PATIENTS WHO ARE HIV ANTIBODY POSITIVE.

Cone, Lawrence; Woodard, D; Wade, D; Curry, W; Boughton, W; Fiala, M. Section of Infectious Diseases, Department of Medicine, Departments of Radiology and Pathology, Eisenhower Medical Center, Rancho Mirage, CA, USA.

Disseminated mycobacteriosis due to M. avium-intracellulare (MAI) or less commonly due to M. tuberculosis (MTB) occurs in nearly 25% of patients with AIDS during the course of their illness. In most individuals the lungs are spared and organisms are found in lymph nodes, blood bone marrow, liver, spleen and gastrointestinal tract. Of 28 patients with AIDS in whom these sites revealed mycobacteria, 18 underwent CT scanning of the abdomen. Whereas all patients with mycobacteriosis exhibited an anemia (<Hb=10 gms), fever (>37.2°C 1 wk), weight loss (>10% in 3 mos), 78% also revealed splenomegaly and 72%, abdominal lymphadenopathy on CT. AIDS patients with other opportunistic infections (OI) (Pneumocystis carinii pneumonia (8), cytomegalovirus infections (11), disseminated coccidioidomycosis (1), and neoplasms (lymphoma (6) and Kaposi's sarcoma (4)) manifested lymphadenopathy in 0-35% except for Kaposi's sarcoma (75%) and coccidioidomycosis (100%), while splenomegaly occurred in less than 25% of patients with Kaposi's sarcoma and PCP. However, individuals with these OI and neoplasms failed to show the universal presence of anemia, fever and weight loss seen in patients with disseminated MAI and MTB. We conclude that this pentad of clinical and radiographic findings existing in HIV antibody positive persons is highly predictive of disseminated mycobacteriosis. This array of events relates to the pathogenesis of mycobacterial disease.

Th.B.P.54 MYCOBACTERIOSES AND AIDS. THERAPEUTIC APPROACHES.

Schürmann, Dirk *; Ruf, B. *; Mauch, H. ** ; Pohle, H.D. *
* II. Department of Internal Medicine, Rudolf Virchow University Hospital, Freie Universität Berlin; ** Heckeshorn Hospital, Berlin, FRG

Objective. To gain data on the effectiveness of chemotherapy in mycobacterioses.
Methods. Course and the effect of therapy was evaluated in 51 patients. Drug susceptibility of strains involved was determined.
Results. Tuberculosis (TB): 17/21 patients were treated (common drugs for 9 months, followed by maintenance therapy). One of 17 (6 %) died of TB, five later on due to other causes. In all untreated cases TB was the cause of death. Follow-up: max. 36 months, patients alive › 1 year (n=7), › 2 years (n=4), no relapses. One of 21 strains was resistant against RMP and INH. All strains were in addition susceptible against rifabutine, clofazimine and ciprofloxacin.
MAI-infection: 17/38 patients were treated, 9 showed at least temporary improvement. 13/16 patients died, 3 due to MAI-infection. MAI was isolated post mortem in all cases in spite of treatment with clofazimine. 4/17 cases diagnosed early improved lastingly and treatment included rifabutine (n=2), and clofazimine and macrolides (n=2). All strains were nearly completely resistant against common drugs and chinolones, but were susceptible against rifabutin and clofazimine (MHK in the range of achieveable serum concentrations).
Conclusions. Therapy of TB is mostly successful. Maintenance therapy seems to be recommondable. MAI-infection treated in an early stage may be curable using modified regimens including rifabutin, clofazimine and macrolides.

Th.B.P.55 DETECTION OF ANTIMYCOBACTERIAL ANTIBODIES IN HIV INFECTION.

Farber,Claire-Michèle*;De Bruyn,J.***;Yernault,J.C.** and Van Vooren, J.P.**

* Department of Immunology and ** Department of Pneumology,
Hôpital Erasme, Université Libre de Bruxelles, Bruxelles, Belgium.
*** Institut Pasteur du Brabant, Bruxelles, Belgium.

Objective. To facilitate the diagnosis of mycobacterial diseases in HIV infected patients.
Methods. A serological assay detecting IgG directed against mycobacterial culture filtrate in HIV positive and AIDS patients with negative (ID -) and positive (ID +) PPD skin tests.

Results.	Negative specific IgG	Positive specific IgG
HIV carriers ID -	5	0
HIV carriers ID +	3	0
AIDS, no tuberculosis	5	0
AIDS, MAI	1	0
AIDS, ganglionnar tuberculosis	0	2
AIDS, pleural tuberculosis	0	1

Conclusion. Detection in the serum of IgG directed against mycobacterial antigens can be of help in the diagnosis of tuberculous disease in HIV infected patients.

Th.B.P.56 CLINICAL IMMUNOLOGICAL AND PROGNOSTIC ASPECTS OF TUBERCULOSIS (TB) IN HIV PATIENTS.

Narciso P.; Leoni G.C.; Sette P.; Spinazzola F.; Tozzi V., Visco Giuseppe et al.
U.S.L. RM/10 "L. Spallanzani" Hospital Dept. Infectious Diseases, Rome, Italy.

OBJECTIVE. To correlate clinical aspects of TB with immunological data. To determine if any among chest X ray (XR) patterns of pulmonary involvement could be a predictor of evolution to overt AIDS.
METHODS. 35 HIV Ab +ve patients with pulmonary and extrapulmonary TB observed since March 1986 to Dec 1988 were evaluated. The mean follow-up time lasted 18 months (range 1-34).
RESULTS

	chest XR pattern		
	miliary	non miliary	p
CD4 + cells (mean ± SD) :	100.9 (± 66.3)	311.8(±263.9)	<0.01
progression to AIDS :	9/10 (90%)	2/14 (14%)	<0.005

Non-miliary patterns were: cavities in 5 cases, upper lobe infiltration in 5, lower lobe infiltration in 3, pleural effusion in 2 cases. Extrapulmonary TB was observed in 10 patients. In ARC cases progression to overt AIDS was observed after a mean of 7 months. When performed in 14 patients 67 Ga lung scanning showed focal or diffuse patterns and/or increased uptake of limph nodes. In 2 patients scintigraphic abnormalities appared before than XR lesions.
CONCLUSIONS. Chest XR miliary pattern in ARC patients with TB seems to be associated with lower CD4+ cell count ($p<0.01$) and with higher probability to develop AIDS within 7 months (<0.005). 67 Ga lung scanning is useful for an early and a more precise detection of pulmonary involvement in patients with TB.

Th.B.P.57 [illegible]

Ocaña I., De Luis A., Ruiz I., Martí R.(*), Vidal R.(**), Martinez-Vázquez J.M.
Departements de Medecine Interne, Microbiologie (*) et pneumologie (**). Hospital Valle de Hebrón. Université autonomique de Barcelone. Barcelone. Espagne.

OBJECTIF: valorer l'incidence et caracteristiques cliniques et radiologiques de la tuberculose (T) chez des malades avec SIDA, et observer la repercusion que represente le fait d'avoir inclus la tuberculose extrapulmonaire (TE) comme critaire diagnostique de definition de SIDA.
MATERIEL ET METHODES: nous avons etudié 145 cas consecutifs de SIDA. Le diagnostique de T fut établi selon critaires bacteriologiques et/ou histologiques.
RESULTATS: Des 145 malades de SIDA, nous avons diagnostiqué 52 T (35.8%), 12 Tuberculoses pulmonaires (TP) exclusivement (23%) et 40 TE (76.9%) étant cette derniere l'infection qui a defini le SIDA dans le 25.6% de nos cas; 37 des 52 malades (71.1%) étaient des droga-adictes. Le PPD était positif dans le 33% des cas. La TP apparut avant le diagnostique de SIDA, environ 12 mois dans le 66% des cas. La clinique plus frequente fut un syndrome fébrile d'environ un mois d'évolution, avec surtout symptomatologie constitutionnelle dans les patients avec TE; dans ceux-ci, l'affectation pulmonaire apparut dans 27 des 40 cas (67.5%) avec dominance de la forme disséminée dans les trois quarts des cas; la presentation adenopatique exclusive apparut en 11 cas et 2 cas avaient exclusivement affectation des meninges. La radiologie toracique, dans la TP qui avait apparu avant le diagnostique de SIDA montra une prévalence d'infiltrats pulmonaires (6/8), même avec cavitation, et chez les malades avec SIDA, soit avec TP ou TE, dans plus de la moitié des cas on pu observer un patron interstitiel accompagné parfois d'adenopaties mediastiniques. Le diagnostique de T a etait fait par culture dans l'expectoration ou rinçage broncho-alveolaire dans les cas de TP et dans la TE on a obtenu des meilleurs resultats a partir de l'étude des cultures des biopsies. On a administré traitement antituberculostatique habituel avec une resolution clinique et radiologique; 5 malades avec TE on souffer hepatotoxicité.
CONCLUSIONS: 1- La T est une infection frequente (35.8%) dans les patients avec SIDA avec une predominance de la TE (77%); 2- radiologiquement, a predominé le patron interstitiel pulmonaire avec ou sans afectation adenopatique; 3- dans la TE les meilleurs resultats ont été obtenus par culture des biopsies correspondantes; 4- on a observé une bonne tolerance et evolution clinique et radiologique avec le traitement antituberculostatique habituel.

Th.B.P.58 Generalized infection with an unidentified acid-fast microorganism (AFB).

Nicolas Mach[1], H. R. Chang[2], J. D. Piguet[4], F. Portaels[5], R. Auckenthaler[2], B. Hirschel[3] et al.
Divisions of [1]Pathology, [2]Microbiology, [3]Infectious Diseases, and the Clinique Médicale, Hôpital Cantonal Universitaire, [4]Institut d'Hygiène, 1211 Geneva 4, Switzerland, phone °01 41 22 22 64 16, and [5]Institut de Médecine Tropicale, Antwerp, Belgium.

Case Report: A HIV-seropositive former i.v. drug user presented with enlargement of liver and spleen; he died 20 months later after a 30 kg weight loss, diarrhea, and ascites.
Results: During life, biopsies of liver and duodenum, ascites, buffy coat, urine and feces all revealed massive amounts of AFB; AFB infiltrated all organs examined at autopsy. Multiple attempts to cultivate the AFB on 10 different media at 30°, 37°, and 45° C failed. Evidence for metabolism was present in liquid Middlebrook 12B and 13A media (Bactec®), but attempts at subculture were unsucessful. The patient had not travelled to areas where leprosy is endemic, and he had no skin or nerve lesions suggestive of leprosy. Gas chromatography revealed clear evidence of tuberculostearic acid indicative of genus *Mycobacterium*, but not of secondary alcohols indicating M. avium-intracellulare. Hybridization of AFB in feces and blood with probes for *M. tuberculosis* complex and *M. avium-intracellulare* was negative.
Material from the patient was injected into 10 immunocompetent Swiss Webster mice. They were sacrificed after 12 months; $3x10^{8}$ AFB were found in 2 footpads of 1 mouse. In contrast, inoculated nude mice died after 2 months; granulomas containing AFB were present in liver and spleen. Control mice sacrificed at the same time did not show any lesions.
Conclusion: This patient died from infection with an unidentified mycobacterium, which behaved clinically like *M. avium-intracellulare*.

Th.B.P.59 TUBERCULOSIS AND AIDS IN FRANKFURT

Müller R., Koller-Lampert L., Jakschik A., Brodt R., Schulze-Werninghaus G., Helm E.B.
Universitätsklinik Frankfurt, Zentrum für Innere Medizin, Infektiologie, Th.-Stern-Kai 7, 6000 Frankfurt/M, FRG

Objective: To describe frequency, clinical picture, course and significance of tuberculosis (TB) with AIDS in Frankfurt.
Method: since 1984, all TB cases with HIV infection have been examined prospectively. All patients (pts) get quadruple standard therapy and are clinically followed up regularly even after completion of treatment.
Results: In 4 years, 48 pts were diagnosed with TB, the total of AIDS pts in Frankfurt being 328. 37% of TB pts were not born in Germany. 10 TB pts have not developed AIDS, in 11 pts, TB was found 6mo before 1st AIDS manifestation, in 9 pts simultaneously, and in 16 pts, 11mo after 1st AIDS manifestation (mean values). 58% had isolated pulmonary TB, 21% had disseminated TB, and 21% had lymph node or renal TB, respectively. Compared with pts negative for HIV, efficacy of therapy was the same, but rate of side effects was significantly higher (7% of tested TB strains were INH-resistant). There was no difference in survival times of HIV-infected pts with TB and non-TB AIDS pts.
Conclusion: In Frankfurt, more than 10% of AIDS pts have TB with frequent dissemination. In spite of good response to standard therapy and unreduced survival times, the course of disease is complicated by frequent side effects and maintanance therapy being necessary for longer time.

Th.B.P.60 MNT INFECTION IN 63 OF 328 AIDS PATIENTS IN FRANKFURT

Koller-Lampert L., Brodt R., Jakschik A., Staszewski S., Helm E.B.
Universitätsklinik Frankfurt, Zentrum der Inneren Medizin, Infektiologie, Th.-Stern-Kai 7, 6000 Frankfurt/M, FRG

Objective: To investigate occurrence and significance of evidence of different mycobacteria in HIV-infected (HIV+)patients (pts) in the course of disease.
Methods: All our HIV+ pts staged WR 4-6 are regularly tested for colonisation and/or infection with MNT (stool, urine, sputum); all pts with microscopic or cultural evidence for MNT get regular physical & immunological follow-ups. All pos. cultures are typed, and resistance is determined.
Results: Of 743 HIV+ pts tested, 63 (8.5%) had MNT (relative to total of AIDS pts [n = 328] 19%); 47 of 63 developed AIDS, 34 died. Except for 16 pts not having developed AIDS and 7 pts with MNT evidence 2mo (mean) before 1st AIDS manifestation, in 7 pts, MNT was found with 1st AIDS manifestation, and in 37 pts, 7mo later, respectively. A comparison of survival times between AIDS pts with MNT and AIDS pts without MNT showed no significant difference. In 42 pts, typing has been completed: MAI 50%, M. xenopi 33%, M. fortuitum 7%, M. kansasii 5%, M. gordonae 5%.
Conclusion: A high percentage of AIDS pts have colonisation with MNT, the frequency of subtypes geographically varying. As in other pts, evidence of MNT does not necessarily mean severe illness.

Th.B.P.61 AMINOGLYCOSIDE ANTIBIOTICS HAVE POTENTIAL VALUE IN THE TREATMENT OF MYCOBACTERIUM AVIUM COMPLEX (MAC) DISEASE IN AIDS PATIENTS

Pattisapu R.J. Gangadharam*; Kesavalu, L.*, Perumal, V.K.*, Parikh, K.* and Ghori, N.* National Jewish Center for Immunology and Respiratory Medicine, Denver, Colorado, U.S.A.

Mycobacterium avium complex (MAC) cause serious opportunistic infections in AIDS patients. We established that the beige (C57Bl/6/bg/bg) mice are most susceptible to experimental MAC infections. In other studies we showed that in many immunobiological respects, beige mice are similar to AIDS patients. Using the beige mouse model we investigated the in vivo chemotherapeutic potentialities of more than 30 drugs. Of these, amikacin demonstrated high in vivo activity. With 50 mg/kg dose (comparable to 15 mg/kg in humans), given intramuscularly (IM) for 6-8 weeks, this drug caused remarkable elimination of MAC from all visceral organs of beige mice infected intravenously with a virulent strain of MAC. Combination chemotherapy with either rifabutin, clofazimine or both proved the major role of amikacin in the in vivo elimination of MAC. Recent studies indicated that streptomycin at a dose of 100 mg/kg given IM demonstrated equal activity to amikacin. Streptomycin being less expensive and more widely used should be valuable in the treatment of MAC disease in AIDS patients.

Th.B.P.62 PLASMIDS INFLUENCE VIRULENCE OF MYCOBACTERIUM AVIUM COMPLEX (MAC) STRAINS IN AIDS PATIENTS

Pattisapu R.J. Gangadharam*; Perumal, V.K*, Crawford, J.H.** and Bates J.H.**, *National Jewish Center for Immunology and Respiratory Medicine, Denver, Colorado, ** VA Hospital, Little Rock, Arkansas, U.S.A.

Mycobacterium avium complex (MAC) organisms are important opportunistic infections encountered in AIDS patients. More than 50% of AIDS patients are known to have MAC infections and most of them succumb to the disease within one year of diagnosis. Among several differences observed between MAC strains from AIDS and non-AIDS patients, plasmids are the most important. All (100%) of MAC strains studied contained plasmids, many of them possessing more than one plasmid, while 35-50% of strains from non-AIDS patients and only 5% of environmental isolates did so. The virulence of MAC strains as categorized by the beige mouse model is directly related to the total number of plasmids and to the number of large (100 m.dal) plasmids. Proof for the importance of plasmids to virulence of MAC is obtained by a comparison of virulence of a strain with plasmids and its plasmid deprived variant. While the former was highly virulent, its plasmid-free variant lost its virulence. The lose of virulence is confirmed by the inverse correlation of oxygen metabolite release from macrophages.

Th.B.P.63 Incidence of adquired immunodeficiency syndrome (AIDS) in outpatients with tuberculosis.

Authors: Ribeiro, S.A.; Togeiro, S.M.; Acreturi, C.A.; Yamashita, H.K. From Escola Paulista de Medicina, S. Paulo, SP, Brasil.

This study was performed in a Health Center from Jan 1, 1987 to Dec 31, 1988; and 15 of 453 (3,3 percent) patients of tuberculosis had AIDS. In Brasil, the Association of both AIDS and tuberculosis had been related as 22% of outpatients and 50% of inpatients. Of 15 cases of tuberculosis and AIDS 87% were males and 13% were females, 21 to 41 years of age. All of them were white, and 73,3% were homosexual, 13,3% had transfusion-associated AIDS and 13,3% were intravenous drug users. 6,7% had tuberculosis diagnosed before AIDS, 46,7% had tuberculosis diagnosed simultaneously and 46,7% had AIDS diagnosed at least 1 month prior to the diagnoses of tuberculosis. 60% of the patients had pulmonary and 40% had extrapulmonary disease. 60% of the patients with tuberculosis and HIV infection responded well to standard antituberculosis drugs; 6,7% had progressive tuberculosis and 33,3% did not have avaliable follow up. Since tuberculosis was diagnosed the mean survival was 13.7 months.

Th.B.P.64 TUBERCULOSE (TB) ET SIDA ; FAITS CLINIQUES OBSERVES EN MILIEU HOSPITALIER PARISIEN ; IMPLICATIONS EPIDEMIOLOGIQUES.

J.Chrétien, PAPILLON Françoise, Université PARIS V, Hopital Laennec. PARIS, FRANCE

Dans le Service de Médecine Pulmonaire de l'Hopital Laennec, ont été recensés entre 1982 et 1988, 427 malades HIV (+) ; tous ont eu un lavage bronchoalvéolaire (LBA) et des examens bactériologiques répétés afin d'étudier l'association de TB et SIDA.
Il est apparu 4 traits particuliers : 1°/ la fréquence élevée de la TB : 12 % des cas de SIDA, 7,5 % des cas HIV (+). 2°/ la sévérité de l'atteinte TB : miliaire 15 %, foyers pulmonaires multiples 20 %, atteinte polyviscérale 21 %. 3°/ la haute densité bacillaire : frottis positif 52 %, culture positive 92 %, taux élevé de résistance des B.K. à INH (22 %) SM (18 %) RMP (7 %). 4°/ la négativité du Mentoux-test, chez plus de 90 % des TB/SIDA en opposition avec la mise en évidence des BK dans de multiples prélèvements. La négativation du Mentoux-test, initialement positif, est en outre observée chez les TB/HIV (+) quand l'évolution se fait vers le SIDA.

Ainsi donc, la singularité des cas de TB/SIDA réside dans la coexistence chez un malade de bacilles tuberculeux et d'un Mentoux-test négatif ; ce caractère est l'une des expressions du SIDA. De même, la négativation progressive du test cutané tuberculinique chez un TB/HIV (+) est un marqueur de l'évolution vers le SIDA.

C'est pourquoi, même si l'on ne dispose pas de la sérologie, il serait possible d'apprécier, dans les groupes de tuberculeux, le niveau de l'endémie HIV en utilisant les deux examens simples et peu onéreux que sont la recherche de BK par microscopie directe et le Mentoux-test. La positivité du premier, associée à la négativité du second traduit le SIDA. Les malades tuberculeux apportent ainsi des indices utiles à l'étude épidémiologique du SIDA.

Th.B.P.65 TUBERCULOSIS IN AIDS PATIENTS.

Iribarren, J.A.; Arrizabalaga, J.; Garde, C.; Muñoz-Baroja, I.; Pérez-Trallero, E.; Zuleica D. Hospital Nª Sª de Aránzazu.San Sebastian.Spain.

Objectives: Evaluation of: a) the prevalence of extrapulmonary tuberculosis in AIDS patients, b) clinical forms of presentation of this disease, c) eventual development of opportunistic infections (OI), d) response to treatment and adverse therapeutic reactions.
Methods: A prospective study was made of 113 patients diagnosed as AIDS in our hospital between 1985 and December 1988. The reasons for instating tuberculostatic treatment served to categorize patients into four groups. I) Disseminated tuberculosis with bacteriological confirmation of M. tuberculosis at two or more different sites. II) Extrapulmonary tuberculosis with lymph node involvement. III) Extrapulmonary tuberculosis without lymph node involvement. IV) Patients with prolonged fever and positive response to tuberculostatic, with or without eventual bacteriological confirmation.
We also evaluated the development of OI, response to treatment and the incidence of adverse reactions to treatment.
Results: Forty tuberculostatic treatment were instated (35,7%): 18 in group I, most (16) with lung disease; 10 in group II; 5 in group III; and 7 on group IV. The incidence of side effects was 10% (4 patients). The type of OI that developed generally varied according to groups, and response to treatment was usually good if the patient's previous status was good.
Conclusions: 1. In areas with an elevated high prevalence of tuberculosis infection, TB is a frequent OI in AIDS patients. 2. An important subgroup of patients debut with prolonged fever and difficult bacteriological demonstration of M. tuberculosis. In these regions, tuberculostatic treatment should be tried before classifying patients as CDC stage IV. 3. The type of OI that developed on tuberculosis varied in accordance with the clinical form of TB. 4. Response to treatment depended on the clinical form and on the patient's general condition.

Th.B.P.66 ASSOCIATION BETWEEN TUBERCULOSIS AND AIDS IN RIO DE JANEIRO - BRAZIL

Morais de Sá, Carlos Alberto; Eyer-Silva, W.; Severo, R.; Guimarães-Dias, M.; Oliveira, D.P.; Sion, F.S. et al.
Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil.

Objective: To study the incidence and characteristics of TB among AIDS patients.
Methods: We retrospectively reviewed the medical records of 235 patients who met the current CDC surveillance case definition of AIDS. We look for clinical, pathological, radiological and microbiological evidence of TB and also compared epidemiological characteristics of AIDS patients with and without TB. Chi-square test was used where appropriate.
Results: TB was observed in 85 (36,2%) patients. Although the lungs were the most frequent site of infection, 58 (68,2%) had at least one extrapulmonary (EPTB) site of disease. Lymph nodes were involved in 43 (50,6%), liver in 11 (12,9%), genitourinary tract in 8 (9,4%), spleen in 7 (8,2%), pericardium in 6 (7,1%), gastrointestinal tract in 5 (5,9%) and meninges in 3 (3,5%). Common associated opportunistic pathogens were C.albicans in 48 (56,5%), T.gondii in 18(21,2%), and Cryptosporidium in 14 (16,5%). Kaposi's sarcoma was observed in 11 (12,9%). We found no statistically significant differences between AIDS patients with and without TB: they were frequently white, middle-aged, homosexual/bisexual males.
Conclusion: 1) These data suggest a strong association between M.tuberculosis and HIV infections in Rio de Janeiro. 2) EPTB is a common feature of AIDS. 3) We found no differences between AIDS patients with and without TB in relation to age, sex, race and risk group. 4) Subsequent studies will be needed to determine the impact of the HIV epidemic on TB prevalence in Brazil.

Th.B.P.67 THE CLINICAL IMPACT OF MYCOBACTERIAL INFECTIONS IN HIV INFECTED PERSONS.

Boldt, Kristi; Chomyc, S.; Miedzinski, L.; Taylor, G. and Evans, G.A.*.
University of Alberta, Edmonton, Alberta, Canada, *University of Calgary, Calgary, Alberta, Canada.

Objective: To assess the impact of Mycobacterial infections in AIDS and HIV infected patients in the Province of Alberta (to date 125 AIDS, 706 known seropositives).
Methods: Mycobacterially infected patients were identified by reviewing laboratory isolates from the Provincial Tuberculosis Laboratory for the period 1985-1988 where AIDS or HIV was noted as a clinical factor. Patient records were then reviewed to assess clinical correlates.
Results: Thirty isolates were grown from 29 patients. Species isolated were: Mycobacterium avium intracellulare (MAI) 22, M.avium intracellulare scrofulum complex (MAIS) 2, M.tuberculosis 6, M.xenopi 1. M.tuberculosis was grown exclusively from non Canadian born persons most of whom did not have AIDS. MAI/MAIS was grown from 19% (24/125) of our AIDS patients. Sites of MAI isolation included blood 48%, stool 43%, sputum 20%, bronchial washings 14%, urine 7%, lymph nodes 3% and other 6%.
Clinically, Mycobacterial infection was the initial presentation of HIV infection in many. Several patients with MAI bacteremia have survived more than one year without treatment.
Conclusion: In our HIV population, M.tuberculosis is exclusively a problem of persons with T.B. endemic areas who usually do not exhibit other features of AIDS. MAI infection is not necessarily a late presenting feature and long term survival can occur without treatment.

Th.B.P.68 POOR COMPLIANCE IS THE MAJOR OBSTACLE IN CONTROLLING THE HIV-ASSOCIATED TUBERCULOSIS (TB) OUTBREAK.

Karen Brudney,MD, J Dobkin,MD, Dept. of Medicine, Harlem Hospital, Columbia U College of Physicians and Surgeons, New York, NY, USA.

Increasing TB in New York City is often linked to the HIV epidemic. However poor compliance(C) is a key factor leading to frequent readmission and probably many secondary cases. The impoverished population at risk for both HIV and TB has features strongly linked to low C: intravenous drug abuse(IVD), unemployment, homelessness, crack use, alcoholism(Alc). All inpatients(pts) at Harlem Hospital diagnosed with TB from 1/1/88-9/30/88 were studied by interview(133) or chart review(95). Of 228 pts 44 (19%) died during initial hospitalization. Of the 181 who were discharged 151 (83%) were lost to follow-up and 30 were compliant. 42/151 (28%) non compliant(NC) pts were readmitted for TB within 1 year and 30 (83%) were lost again.

Factor-	M	F	IVD	Crack	Gay	NR	Alc+	Alc-	Hm-	Hm?	Hm+	Jb-	Jb+	AA	HIV+	HIV-
%NC -	81%	95%	81%	94%	50%	88%	93%	69%	88%	81%	74%	83%	75%	64%	96%	82%
# Pts -	144	37	91	18	6	50	78	72	64	38	46	128	31	53	25	27

(M=male,F=female;crack=non-IVD crack user;NR=no HIV risk;Hm-=lives in street/shelter;Hm?=unstable housing; Hm+=apartment;Jb-=nojob>1year; Jb+=regular work;AA=AIDS/ARC on admission for TB; HIV+=HIV+ without AA)

AA pts had higher C than HIV+ or HIV-, probably because their HIV disease led them to seek ongoing medical care. However, NC AA pts were more likely to be readmitted for TB than non-AA NC pts(37% vs 30%). F were more likely than M to be NC(95% vs 81%) perhaps due to a higher rate of crack use(24% vs 6%). Alcoholics had significantly poorer C in all subgroups. JB- and Hm- were highly prevalent overall but tended to be more common in NC pts. New strategies are needed to treat pts most likely to have HIV and TB.

Th.B.P.69 SUCCESSFUL ANTITUBERCULOUS TREATMENT WITH VARIOUS DRUG REGIMENS IN PATIENTS WITH HIV INFECTION.

Carton J.Antonio, Circate V, Maradona JA, Moris J, Ferro J, Colmeiro A, et al. HOSPITAL UNIVERSITARIO. OVIEDO. SPAIN.

OBJECTIVE: To asses short-term efficacy and toxicity for several antituberculous drug regimens in patients with HIV infection and tuberculosis (TB).
METHODS: 53 patients with HIV infection and TB (72% culture and sensitivity proved) received antituberculous therapy; drugs used and daily dosages were: Rifampin (RMP), 600 mg; Isoniazid (INH), 300 mg; Ethambutol (EMB), 1200 mg; Pyrazinamide (PZA), 2000 mg; Streptomycin, 1 g. A total of 61 therapeutic courses were distributed in: Regimen A: RMP and INH for 9 months (m) plus EMB during the first 2 m. Regimen B: RMP and INH for 6 to 9 m plus EMB and PZA during the first 2 m. Regimen C: Patients in whom RMP and/or INH had to be avoided and received other drug combinations. Drugs were self-administered and efficacy assesed after 6 m of chemotherapy. Presently, 25 patients have completed treatment having a mean subsequent follow-up of 17.6±14 m. Pulmonary TB (PTB) was found in 25 patients, extrapulmonary (ETB) in 13 and disseminated (DTB) in 15. Two patients had been previously diagnosed of AIDS and 12 of chronic hepatitis.
RESULTS: TB cure was reached in 44 patients (90%); 5 of them died from causes unrelated to TB and another 5 (10%) died during the course of treatment with probable active TB. Drug toxicity was appreciated in 9 patients (16%). The main differences among regimens were:

	REGIMEN A	REGIMEN B	REGIMEN C	P VALUE (*)
Complete / incomplete courses	22/7	19/7	3/3	
Lost/toxicity/Relapses/death	0/1/3*/2	4/3/0/0	0/0/0/3	0.08
PTB / ETB / DTB	15/6/8	12/6/8	1/2/2	
CD4 /µL (X̄ + SD)	249 ± 184	271 ± 246	90 ± 73*	0.05
Cure / failure	22/7*	19/0	3/3	0.05
Side effects	3.4 %	31 %*	0	0.01
Survival since diagnosis (m)	17 ± 16.5	16 ± 13	9 ± 7	

CONCLUSION: In the short-term, results in HIV-patients resemble that obtained for TB in immunocompetent subjets. Effective therapy can be expected mainly if INH and RMP are included in the regimen. Four-drug chemotherapy seemed superior to the three-drug regimen, which showed more relapses but a lower toxicity. Due to the delayed presentation and short follow-up of the severest cases, results could worsen in the future.

Th.B.P.70 NATURAL HISTORY OF M. LEPRAE AND HIV CO-INFECTION

Pean, Claude*, Pape,J.W.***, Deschamps,M-M.** , Dambreville, M.*, Johnson,W.D.Jr.***.
*Inst. Cardinal Leger contre la lèpre, FAME PEREO and **GHESKIO, P-au-P. Haiti ***Cornell University Medical College, New York, NY., U.S.A.

Objective To determine the natural history of leprosy in HIV-infected patients.
Methods We studied 275 leprosy patients between 1985 and 1988. HIV testing on all patients utilized an ELISA with RIA confirmation. The diagnosis and treatment of leprosy were according to WHO criteria and protocols. Patients were followed at least monthly during therapy and at 3 month interval thereafter.
Results Patients were 5 to 90 years old (mean, 33 yrs). Two hundred patients had the tuberculoid form and 75 were lepromatous. The HIV seropositivity rate was 6.5% (18/275) for the entire cohort, 9.4% (18/191) for those between 15 and 60 yrs. The rate was comparable for both forms of leprosy. Twenty-two per cent (4/18) of HIV-seropositive (HIV +) asymptomatic patients developed new skin lesions and lepromin anergy during dapsone/rifampin therapy, as compared to 2/257 (0.8%) of HIV-seronegative patients. All patients who developed new lesions had tuberculoid leprosy. In HIV + patients, new lesions appeared a mean of 4.8 months (3-7 mo) after the initiation of therapy and preceded the onset of HIV-associated illness by a mean of 21 months (12-31 mo). Ten additional HIV + tuberculoid patients developed AIDS or HIV-associated illness during the follow-up period but did not develop new leprosy lesions.
Conclusion Leprosy may represent another opportunistic infection of AIDS and also accelerate the appearance of the classic AIDS illness.

Th.B.P.71 Mycobacterium avium-intracellulare infection limited to the skin and lymph nodes in pateints with AIDS

Barbaro, Daniel*, Orcutt, VL.**, Coldiron, BM.***
*Dept. Internal Medicine, University of Texas Southwestern Medical School, **Parkland Memorial Hospital, Dallas, Tx. ***Dept. of Dermatology, University of Texas Southwestern Medical School, U.S.A.

Three patients with the acquired immunodeficiency syndrome (AIDS) developed cutaneous abscesses from which Mycobacterium-avium intracellulare (MAI) was isolated. All three patients had begun therapy with zidovidine (AZT) within three months prior to their presentation. Patients were treated with incision/drainage/wound packing as well as short courses of routine antituberculous therapy. No evidence of dissemination was found by blood culture or bone marrow biopsy and culture. All three lesions healed completely within three months, despite the discontinuation of isoniazid, rifampin and ethambutol after cultures returned positive for MAI. This rare form of localized presentation of MAI is speculated to be an effect of zidovidine on this disease process.

Th.B.P.72 MYCOBACTERIAL INFECTION IN AIDS PATIENTS

Damiano F.*, Fantoni M.*, Ventura G.*, Antinori Andrea*, Ardito F.**, Archibusacci C.** et al.
*Clinica Malattie Infettive, **Microbiologia-Università Cattolica-Roma-Italy

Objective: To evaluate the frequency of mycobacterial infection in AIDS pts.
Methods: 33 consecutively followed pts were examinated for the presence of mycobacteria in clinical specimens (blood, bone marrow, sputum, Bal, urine, stool, spinal fluid, biopsies) using standard techniques.
Results: Four pts (12,1%) had disseminated tuberculosis and M. tuberculosis (M.tb) was cultured in blood (1/33) and in bone marrow (3/33). Three pts (9%) had pulmonary tuberculosis (isolation from sputum or Bal). One pt had an extra-pulmonary disease with isolation of M.tb from lymphonodes and spleen. Dissemination was due to M. avium-complex (MAC) in 4 pts (12,1%) isolation from blood in 2 cases, from bone marrow in one case and from blood, bone marrow, sputum, urine and stool cultures in one pt. One pt had disseminated infection due to M. fortuitum-complex (M.fc) proven by blood and bone marrow cultures. Colonization with other mycobacteria was due to: M. terrae-complex (M.tc) in 7 pts (21,2) (4 urine, 2 Bal, 1 sputum); M. gordonae (M.g) in 4 pts (21,1) (2 urine, 1 Bal, 1 colonic biopsy); M.fc in one pt (sputum and urine). Mtc and M.g were detected each one in 3 pts with concomitant infection by M.tb and MAC.
Conclusion: M.tb and MAC are important and frequent opportunistic agents in AIDS pts; the role of the other non-tuberculous mycobacteria as opportunitic pathogens in these pts needs further studies.

Th.B.P.73

EPIDEMIOLOGICAL AND ENVIRONMENTAL FEATURES OF MYCOBACTERIA OTHER THAN TUBERCULOSIS IN GERMANY.

Peters, Malte*; Ruf, B.*; Schürmann, D.*; Schröder, K.-H.**; Mauch, H.*** and Pohle, H.-D*. - *II. Department of Internal Medicine, Rudolf Virchow University Hospital; **Forschungsinstitut Borstel, Borstel; ***Heckeshorn Hospital; FRG.

Mycobacteria other than tuberculosis (MOTT) are common pathogens in AIDS patients. Mycobacterium avium-intracellulare (MAI) are the most important atypical mycobacteria species. To evaluate whether infections and colonisations with MOTT are common only in HIV infected patients, the frequency of MOTT in immunosuppressed patients without HIV infection was investigated. Blood, stool and urine specimens from 134 patients with non-HIV related immunosuppression were examined for mycobacteria. Mycobacteria have not been found. Additionally gastrointestinal biopsy specimens from 170 immunocompetent patients were examined histologically and microscopically. MOTT were isolated from one patient.

By contrast, in 58 of 190 AIDS patients MOTT have been found. 55/58 isolates were differentiated as MAI. 48 of these MAI isolates were identified as serovar 8/21. In contrast to our findings, serovar 4 is most frequently found in patients with AIDS in the USA. These results do not seem to be attributable to a different pathogenicity of the various serovars but suggest geographical predominances.

MOTT are ubiquitous environmental contaminants, frequently isolated from soil and hospital water supply in examinations performed in the USA. In our investigations we have recovered MOTT in 63 of 170 (37 %) of hot and cold water sites and in 3 of 20 soil samples. M. chelonae, M. gordonae, and M. gastri were found most frequently, whereas MAI have not been isolated.

Th.B.P.74

TUBERCULOSIS AND AIDS-RIO DE JANEIRO, BRAZIL :1983-1988.

Kritski, A.L.*; Matida, A**; Galvão-Castro, B.***.
*Institute of Phtysiology and Pneumology, Federal University of Rio de Janeiro(RJ); **Department of Transmissive Disease-State's Secretary of Health-RJ; ***WHO Collaborating Center-FIOCRUZ-RJ, BRAZIL.

OBJETIVE To describe clinical aspects of patients with AIDS and Tuberculosis (AIDS/TB) and compare to AIDS patients without TB (AIDS/NON TB).
METHODS 718 persons meeting the CDC(1987) or Brasilian Ministry of Health (1987)criteria of AIDS reported form State of Rio de Janeiro, in the period 1983-1988 (24th week ending) were analysed.
RESULTS Among 718 AIDS patients, 171(23.8%)were also diagnosed as having TB. The number of AIDS/TB patients by year rose progressively from zero in 1983 to a peak of 76 in 1987; this number fell to 43 in 1988. The interval between reported of TB and diagnosis of AIDS ranged from 29 months before to 06 months after AIDS diagnosis; 29(16.9%)the diagnosis of TB preceded more than 1 month the diagnosis of AIDS, 127(74.2%) was made within a month before or after the diagnosis of AIDS and 15(8.9%) more than 1 month after the AIDS's diagnosis. AIDS/TB pts. were similar to AIDS/NON-TB patients with respect to age, sex, homo or bisexualism in men, intravenous drug addiction, blood transfusion and were more frequently in heterosexualism transmission (12.7% versus 3.3%). In 163 AIDS/TB patients; 109(66.8%) had pulmonary iuvolvement alone or associated to others organs; 55(33.7%)Lymphatic and 22(13.7%) disseminated form.
CONCLUSION In Rio de Janeiro, tuberculosis associated with AIDS is becoming high and is urgent to initiate research programs of HIV-related tuberculosis as a basis for intervention.

Th.B.P.75

HIV INFECTION ALTERS IMMUNE RESPONSE TO CIGARETTE SMOKING

Royce, Rachel and Winkelstein W. Jr. University of California at Berkeley, Berkeley, California, United States

Objective. To investigate immune response to smoking and HIV infection.
Methods. CD4 and CD8 T cell counts (cells/ul), smoking status and smoking dose (packs/day) were evaluated twice yearly for 3.5 years in the San Francisco Men's Health Study cohort, a probability sample formed in 1984.
Results. In 586 men not infected with HIV, initial CD4 and CD8 T cell counts were significantly higher ($p<.001$) in smokers compared to nonsmokers. Mean CD4 T cell counts increased with smoking dose ($p<.001$). During 3.5 years follow-up, significant differences persisted in CD4 and CD8 T cell counts by smoking status. In contrast, among 386 healthy HIV infected men, CD4 and CD8 T cell counts were not significantly different during the observation period, and no dose response in mean CD4 T cell counts was apparent ($p=.28$).

Packs/day	0		<1/2		1/2-1		1-2		2+	
Mean CD4	$\bar{X}$	(N)	$\bar{X}$	(N)	$\bar{X}$	(N)	$\bar{X}$	(N)	$\bar{X}$	(N)
HIV-	1001	(379)	1118	(29)	1130	(47)	1278	(97)	1138	(34)
HIV+	659	(199)	727	(18)	663	(34)	679	(83)	775	(36)

The percent difference in initial mean CD4 T cell count between smokers and nonsmokers was highest in uninfected men (23%) and lowest in men seropositive at study onset with an unknown duration of infection (7%). The percent difference was intermediate when measured at time of infection in 37 men who HIV seroconverted during the study period (14%).
Conclusion. Proliferation of T cells in smokers may indicate an activated immune response. In HIV infected men, immune response to smoking appears to be depressed and this effect may be related to duration of infection.

Th.B.P.76

NON SPECIFIC PNEUMONITIS (NSP) IN HIV SEROPOSITIVE ADULTS

Gritti Francesco M.,*Poletti V.,*Spiga L.,Sabbatani S.,Grillo A
Infect.Dis.Dep.,Ospedale Maggiore and*Pneumology Dep.,Ospedale Bellaria, Bologna, Italy

Objective. To determine incidence of NSP, which occurs in some HIV seropositive adults,and to compare usefulness of different procedures for its diagnosis.
Method. This is a retrospective study of 11 NSP diagnosed by transbronchial biopsy (TBB) on 63 HIV positive patients (pts) with respiratory symptoms. All underwent TBB,BAL with cellular differential count, coltures,hystological evaluation, standard chest X-rays, haemogasanalysis, Ga67 pulmonary scan, and peripheral lymphocyte subsets count.
Result. Mean peripheral CD4 lymphocytes were 268±84/cmm; only one pts showed a reticular-interstitial pattern on chest X-rays, 1 had low PaO2 and 2 increased Ga67 pulmonary uptake. Cell count on BAL fluid was 526±168x10^3/ml: macrophages 74%,Lymphocytes 6%,neutrophils 20%,which is significantly different from our findings in P. carinii pneumonia: 254±142x 10^3 /ml: macrophages 81 %, lymphocytes 14%,and neutrophils 5%. Five of 8 ARC developed AIDS within 6 months and 5 died within 18 months of NSP diagnosis.
Conclusion.NSP represents 17.5% of our HIV infected adults with respiratory involvement. Lung biopsy remains fundamental for NSP diagnosis while non invasive procedures are only complementary. Neutrophilia of BAL liquid, if further confirmed,could represent another useful marker of this pathology.

Th.B.P.77

EXPRESSION OF CELL SURFACE "ACTIVATION" ANTIGENS IN BRONCHOALVEOLAR LAVAGE (BAL) T CELLS FROM HIV-INFECTED PATIENTS UNDERGOING PNEUMONITIS.

J.ANCOCHEA;L.JIMENEZ;A.GONZALEZ;I.SANTOS;F.SANCHEZ MADRID;M.LOPEZ-BOTET.
Department of Pneumology, Microbiology, Internal Medine, Immunology. Hospital de la Princesa. MADRID. SPAIN.

In the present study we comparatively analysed the cell surface phenotype of T cells obtained from BAL (BAL-T) and peripheral blood (PB-T) in twenty HIV-infected patients with pneumonitis. Samples derived from a control group of ten HIV (-) patients with non infectious miscellaneous lung disorders were as well analyzed. T cells were obtained by sequential centrifugation on Ficoll/Hypaque, plastic adherence and nylon wool-column filtration. Cells were labeled by indirect immunofluorescence with a panel of monoclonal antibodies specific for the following surface antigens: CD 45; CD 3; CD 4; CD 8; CD 28; CD 16; CD 11b; CD 14; transferrin receptor (TrR); VLA-1; MHC class II (DR); CD 38; CD 25; 4F2 and a novel early activation antigen (gp 33/28), preliminarily designated as Activation Inducer Molecule (AIM) (1).

Samples were analyzed by flow cytometry. Our results can be summarized as follows: 1.- The proportions of CD 4(+) lymphocytes were significantly decreased in both PB-T and BAL-T samples from HIV (+) patients as reported by others. 2.- The proportion of some activation antigens such as 4F2, DR, CD 38, VLA-1 and gp 33/28 were significantly increased in BAL-T as compared to PB-T in both groups (HIV (+) and control) of patients. In contrast no significant increment of the CD 25 (+) or TrR (+) cells was observed. 3.- The expression of such activation antigens was significantly higher in the HIV (+) BAL-T as compared to the control samples.

Altogether our data indicate that a substantial proportion of BAL-T cells from HIV-infected patients display phenotipic features that presumably reflect antigen specific stimulation.

Th.B.P.78

MECHANISMS UNDERLYING THE FUNCTIONAL IMPAIRMENT OF PULMONARY NK CELLS FROM PATIENTS WITH HIV INFECTION

Agostini, Carlo* ; Zambello, R.*; Poletti, V.**; Trentin, L.*; Spiga, L.**; Gritti, F.**; Masciarelli, M.*; Semenzato, G. *
* University of Padua, Padua, ** Bellaria and Maggiore Hospitals, Bologna, Italy.

Objective. We previously demonstrated that in the lung of patients with AIDS NK cells are quantitatively increased but do not kill NK-sensitive cells (Am Rev Respir Dis 1988; 138:1609). To evaluate the mechanisms accounting for this functional impairment, lymphocytes recovered from the bronchoalveolar lavage (BAL) fluid of 7 patients with AIDS, 6 patients with ARC, and 1 patient with LAS were investigated for their ability to bind, recognize and lyse K-562 targets.
Methods. Analysis of cell mediated NK activity was performed at resting conditions and after stimulation with IL-2 (100 U/ml) both in ^{51}Cr release and in single cell assays. The release of NK cytotoxic factors (NKCFs) by unstimulated or PHA (5 µgr/ml)-treated BAL cells was also evaluated.
Results. The frequency of conjugates between BAL lymphocytes and K-562 targets did not significantly differ in HIV patients with respect to controls. BAL cells from AIDS patients and from 4 out of 6 ARC patients showed a defective NK activity both in single cell and in ^{51}Cr assays, whereas in the subject with LAS the NK function was comparable to controls. IL-2 treatment of patients' BAL cells resulted in an enhancement of the NK cell killing. The release of NKCFs by unstimulated lung cells from AIDS patients was undetectable, but in 2 subjects with the full-blown syndrome the NKCF production was partially restored following PHA. BAL cells from the LAS patient and from the majority of ARC patients produced discrete amounts of NKCFs and/or could be triggered to release significant amounts of NKCFs by lectin treatment.
Conclusions. In patients with AIDS the defect of lung NK cells is primarily at the post binding stage of the cytotoxic pathway. The impairment of the pulmonary NK system may be involved in the development of lethal pulmonary opportunistic infections characterizing the syndrome.

Th.B.P.79

ALVEOLAR MACROPHAGES FROM PATIENTS WITH HIV INFECTION SPONTANEOUSLY RELEASE TUMOR NECROSIS FACTOR

Agostini, Carlo*; Trentin, L. *; Poletti, V.**, Zambello, R.*; Spiga, L.**; Gritti, F.**; Feruglio, C. *; Semenzato, G. *
* University of Padua, Padua ** Bellaria and Maggiore Hospitals, Bologna, Italy.

Objective. To clarify whether HIV infection affects functional capabilities of alveolar macrophages (AM), AMs from bronchoalveolar lavage (BAL) of 6 patients with full-blown AIDS and 4 patients with ARC were examined for their ability to kill tumor necrosis factor (TNF)-susceptible tumor cells and to release TNF.
Methods. Unstimulated AMs freshly recovered from BAL were tested against U937 target cells in an overnight ^{51}Cr release cytotoxicity assay. In addition, cell free supernatants obtained from unstimulated and IFN-γ (100U/ml), PMA (10 ng/ml), and LPS (5 μg/ml) treated AMs were tested for their cytotoxic activity against U937 targets in an overnight ^{51}Cr release assay. To confirm that TNF was the cytotoxic factor, pretiter anti-TNF MAb (Genzyme) was added to the cell free supernatants in the TNF bioassay.
Results. Unstimulated AMs from patients with AIDS and ARC exhibited a significative lytic activity against U937 targets at all effector:target ratios tested whereas normal AMs did not kill TNF-susceptible tumor cells ($P<0.001$). Supernatants from unstimulated AMs of HIV patients showed significantly higher levels of cytotoxicity with respect to normal AMs ($p<0.001$). Incubation of AMs with anti-TNF MAb inhibited the cytolytic effect exerted by supernatants. Treatment of AMs from HIV patients with IFN-γ, PMA and LPS failed to enhance the TNF production, whereas following these stimuli normal AMs significantly increased their TNF activity.
Conclusions. AMs from patients with HIV infection are activated and spontaneously release TNF. The hightened capacity of HIV AMs to produce TNF may be involved in the pathogenesis of pulmonary complications observed in patients with AIDS.

Th.B.P.80

CD4 LYMPHOCYTE COUNTS AND SERUM P 24 ANTIGEN OF NO DIAGNOSTIC VALUE IN MONITORING HIV INFECTED PATIENTS WITH PULMONARY SYMPTOMS.

Orholm, Marianne, Nielsen, TL, Lundgren, JD.
Department of Infectious Diseases, Hvidovre Hospital, University of Copenhagen, Denmark.

The aim of this study was to determine if the prognostic markers CD4 lymphocyte count and serum HIV p24 antigen were of any diagnostic value in HIV infected patients with pulmonary symptoms.
Method: During 1987 and 1988 143 fiberoptic bronchoscopic procedures were performed on 104 HIV infected patients with pulmonary symptoms. The bronchoscopic specimens were evaluated for Pneumocystis carinii (Pc), cytomegalovirus (CMV) and other pathogens. CD4 counts and serum p24 antigen were measured within 2 weeks before or after the bronchoscopy.
Results: Pulmonary opportunistic infection (o.i.) was found in 81 examinations (Pc=79, CMV=2). There was no difference in CD4 counts between the patients with and without o.i., $p=0.85$. The CD4 count was <200 in 67% and in 62% respectively. 41% of the patients with o.i. had p24 antigen, while this was the case in 42% of the patients without o.i. 32% of the patients in both groups had CD4 count below 200 combined with presence of serum p24 antigen. Conclusion: The CD4 count and p24 antigen have been shown in this study to be of no diagnostic value in monitoring HIV infected patients with pulmonary symptoms.

Th.B.P.81

IMMUNOLOGICAL SUBTYPING OF LEUCOCYTES OBTAINED FROM BRONCHOALVEOLAR LAVAGE (BAL) AND PERIPHERAL BLOOD IN HIV-INFECTED PATIENTS WITH PNEUMONIA.

Kägi, M.K.; Fierz, W.; Kronauer, C.; Speich, R.; Russi, E. and Grob, P.;
University Hospital, Zürich, Switzerland.

Objective. Recent reports have revealed that differential cell counts in bronchoalveolar lavages (BAL) of HIV-infected patients with pneumonia may provide important prognostic information. To further investigate these findings and to characterize the local immunological situation in the lungs we studied leucocytes of BAL compared to peripheral blood leucocytes by means of immunological subtyping. 11 HIV-positive patients with clinical signs of acute pneumonia (chest X ray, physical examination) were evaluated. Six of our patients suffered from histologically confirmed Pneumocystis carinii pneumonia (PCP) and five patients had pneumonia other than PCP.
Methods. Leucocytes obtained from BAL and peripheral blood were double-stained with the following combinations of monoclonal antibodies: CD3 / HLA-DR; CD4 / 4B4; CD8 / HNK1; CD20; CD14 / HLA-DR. Two-color immunofluorescence flow cytometry was carried out using an EPICS™ PROFILE system (Coulter).
Results. Major differences between BAL and peripheral blood could be found with CD8 / HNK1 and CD14 subtyping. The ratio of CD8/HNK1-double-positive cells to CD8-positive cells was higher in the peripheral blood than in BAL leucocytes, particularly in bacterial pneumonias as compared to PCP. The percentage of CD14-positive monocyte/macrophages was much higher in BAL than in peripheral blood, which was in contrast to findings in non-HIV-infected patients with pneumopathies.
Conclusion. The data indicate that in HIV-patients with pneumonia major immunological differences between BAL and peripheral blood are present, which could be relevant for the prognosis.

Th.B.P.82

CUTANEOUS DELAYED HYPERSENSITIVITY IN DRUG ADDICTS.

Villa Antonio, Crucci V, Grondona C, Guareschi G, Pedicconi AM, Confalonieri F.
Fatebenefratelli Hospital, Milan, Italy.

Objective. To evaluate the utility of cutaneous delayed hypersensitivity(CDH) tests in drug addicts (DA) and to apply them the Walter Reed Classification(WRC).
Methods. We studied 127 DA (95 male and 32 female), mean age 29 years; 60 HIV+ and 67 HIV-. Clinical examination, T4 and T8 counts and skin test (Multitest CMI, Mérieux) were done. WRC has been used to classified the patients (pts).
Results. There were significative differences between HIV+ and HIV- for T4/mm^3 (777±375 vs 1370±501, $p<0.0005$), T8/mm^3 (1211±456 vs 1013±385, $p\leq0.005$), number of positive reactions to antigens on DCH tests (1.6±1.3 vs 2.5±0.9, $p<0.0005$) and score (6.2±6.1 vs 8.8±4.2, $p<0.005$). Thirty-four pts resulted hypoergic (17 HIV+ and 17 HIV-); 18 pts resulted anergic (16 HIV+ and 2 HIV-). The pts were classified as follows: WR0, 48 (37.8%); WR1, 9 (7.1%); WR2, 11 (8.7%) (including 3 in WR2B); WR3, 5 (3.9%); WR4, 5 (3.9%); WR5, 8 (6.3%) (including 1 in WR5B and 1 in WR5CNS); WR6, none. Thirty-nine pts (30.7%) (20 HIV+ and 19 HIV-) with partial or complete anergy and counts of T4 lymphocytes above 400/mm^3 did not fit into any stages of the WRC. Also 2 pts (1.6%) HIV+ with T4<400/mm^3 and normal skin test were unclassificable.
Conclusions. CDH is diminished in the DA (also HIV-). Skin tests may be an useful test to evaluate DA immunologic state and they worsen significantly in the HIV+ subjects. The WRC does not accommodate all DA subjects, because of their "background" immunologic abnormalities.

Th.B.P.83

INCREASED PRODUCTION OF SOLUBLE IL 2 RECEPTOR IN PATIENTS WITH HIV INFECTION

Yokota, Yasuko*; Kitamura, K.*; Matsuda, K.*; Mitsuyasu, R.**; Chermann, J-C.*** and Honda, M.*.
*National Institute of Health, AIDS Research Center, Tokyo, Japan, **UCLA Medical Center, Los Angeles, California, U.S.A., ***Institut National de la Sante et de la Recherche Medicale (INSERM), Marseille, France.

Objective. To see whether the production of soluble IL 2 receptor (sIL 2R) in patients with HIV infection increases as the disease advance and correlates with other clinical parameters.
Methods. Two monoclonal antibodies against IL 2R were used for the fluorescence sandwich ELISA. Sera of patients with HIV infection were collected from UCLA Medical Center and INSERM of France and grouped according to the CDC classification of AIDS.
Results. Elevated sIL 2R levels were observed in the sera of patients with HIV infection. Moreover, sIL 2R levels gradually increased as the disese advanced. Statistical analysis showed a negative correlation of those with CD4 cell counts, lymphocyte counts, and CD4-CD8 ratio, but neither WBC counts nor B cell counts correlated. We examined the production of sIL 2R in vitro. Neither PBMC of AIDS patients nor andy of the 19 HIV-1- or HIV-2-infected cell line cells produced sIL 2R in the supernatant, while PBMC of patients with HTLV-1 infection or HTLV-1 positive cell line cells produced sIL 2R.
Conclusion. We observed gradually increased serum level of sIL 2R in patients with HIV infection as the progression of the disease, and this level was negatively correlated well with CD4 cell counts. From in vitro study, it was suggested that these sIL 2R might be produced by non-T cells.

Th.B.P.84

CHANGES IN CD-16 RECEPTOR EXPRESSION ON THE NEUTROPHILS OF HIV INFECTED INDIVIDUALS

Boros. Peter. Bekesi, G. Roboz. J. and Unkeless. J.C.
Mount Sinai School of Medicine. New York City. New York, U.S.A.

Objective. To examine changes in the expression of CD-16 receptor on the neutrophils from HIV infected individuals.
Methods. Leukocytes from whole blood samples from HIV infected individuals in various clinical stages and normal volunteers were double stained with mAb phycoerythrin-Leu 15 (anti CD11b) and fluorescein-3G8 (anti-CD16 or Fc$_\gamma$RIII). As a control, we used the anti-CDw32 (Fc$_\gamma$RII) mAb FITC-IV.3. Analysis was carried out on FACSTAR II cell sorter.
Results. A significant decrease in the CD16 receptor expression has been found in HIV-infected patients compared to normal individuals. The greatest number of CD16-negative neutrophils was measured in patients with AIDS. No correlations were found with the T4/T8 ratio. CDw32 expression on the neutrophils was not affected.
Conclusion. Neutrophil Fc$_\gamma$RIII (CD16) is a phosphatidyl-inositol glycan-linked membrane receptor that is released following treatment of neutrophils with phorbol esters. The finding of decreased CD16 expression might reflect prior activation of neutrophils and might be a marker of the neutrophil dysfunction leading to common bacterial and fungal infections in advanced HIV infections.

Th.B.P.85

ADENOSINE DEAMINASE ISOENZYME IN RETROVIRUS INFECTED DISEASES

Yokoyama, Mitchel Mitsuo and Tsuboi, I.
Kurume University School of Medicine, Kurume, Fukuoka, Japan.

Objective. ADA isoenzyme levels in sera of patients with adult T-cell leukemia(ATL) and acquired immunodeficiency syndrome(AIDS) were analysed.
Methods. Total ADA activity was determined by an enzyme spectrophotometric assay. ADA isoenzyme activity which was inhibited by erythro-9(2-hydroxy-3 nonyl) adenine was designated as ADA1 and the remaining activity as ADA2.
Results. In the case of ATL subtypes, ADA1 activity was significantly elevated in acute and lymphome types($p<.01$) in comparison to chronic and smoldering types. No significant difference in ADA1 activity was noted in smoldering type as compared with chronic type of ATL. ADA2 activity was elevated in sera of acute, lymphoma and chronic types of ATL patients(p .001) as compared with smoldering ATL and HTLV-I carriers. In the case of human immunodificiency virus-I(HIV-I) infections, ADA isoenzyme activities were higher in sera of patients with AIDS and HIV-I antibody-positive individuals in homexuals($p<.001$) when the results were compared with HIV-I antibody-nagative homosexuals and normal controls. A significant elevation of ADA2 activity was seen in sera of AIDS patients($p<.01$) than that of HIV-1 antibody-positive homosexuals.
Conclusion. ADA isoenzyme activities in sera of patients with retrovirus infection reflact the condition of these diseases. To measure of ADA isoenzyme activities may therefore provides and additional parameter for distinguishing subtypes of ATL and may prove to be considerable prognostic and therapeutic monitors in retrovirus infection.

Th.B.P.86

CD4+/NEOPTERIN RATIO CORRELATES WITH P24 ANTIGENAEMIA IN HIV INFECTED PATIENTS.

Crocchiolo Paolo, Lizioli A., Bedarida G., D'Agostino F., Cambiè G., Cantaluppi P.-Ospedale Maggiore -20075 LODI (I) ITALY

Objective: to verify the possible correlation between CD4/neopterin Ratio (R) and p24 antigenaemia (p24Ag) during HIV infection.
Methods: 72 patients (64 males, 8 females; mean age 24.2, range 18-33 years) were classified according to the WRSS criteria; they were also tested for p24Ag and serum neopterin levels (SNL); R was also calculated for each patient.
Resuts: WR2 group (32 pts): 6/32 were p24Ag pos. (18.75 %)
WR5 group (16 pts): 4/16 were p24Ag pos. (25.00 %)
WR6 group (24 pts): 16/24 were p24Ag pos. (66.0 %)

Ratio means:	WR2	WR5	WR6
p24Ag pos.	9.23	9.3	2.9
p24Ag neg.	36.37	17.9	4.0

Conclusion: confirming literature data, we found a good correlation between p24Ag and clinical stage; a good correlation was also found between R and the WRSS. We point out the high significance of R ($p<0.001$) in differentiating, within the WR 2 class, p24Ag pos from p24Ag neg patients with all the prognostic implications involved. By contrast as far as WR 5 and especially WR 6 classes are concerned lower differentiating significances of R mean values point to disease progression and clinical deterioration reflecting increasingly severe immunological disorder regardless of the patients' p24Ag status.

Th.B.P.87

LYMPHOCYTE REACTIVITY TO ANTI-CD3 AS A PROGNOSTIC MARKER IN HIV-1 INFECTED HOMOSEXUAL MEN

M. Roos, F. Miedema, F. de Wolf*, J. Lange*, P. Schellekens. Central Lab. Netherl. Red Cross Blood Transf. Service and the Lab. of Exp. and Clin. Immunology of the Univ. of Amsterdam, *Academic Medical Centre, Amsterdam, The Netherlands.

Objective. In patients with ARC/AIDS, lymphocyte reactivity to antigens declines earlier and more severely compared to nonspecific mitogen responses. Because antigens stimulate T cells via the Ti/T3 complex we studied whether aCD3 reactivity followed the same pattern as antigen reactivity and could be used a a prognostic marker for AIDS.
Methods. Reactivity was measured to aCD3 in Whole Blood Lymphocyte Cultures (WBLC) in a longitudinal study of seropositive homosexual men and expressed as % reactivity per T lymphocyte compared to healthy controls.
Results. In HIV-1 infected asymptomatic men, the response towards ALS and PHA was stable (75%) for 40 months after intake into the study, whereas the response to aCD3 showed a gradual decline (from 70 to 40%) during the same period. In the population that developed AIDS-OI the ALS reactivity remained largely unaffected until 3 months before diagnosis; PHA reactivity started to decline (from 60 to 10%) from about one year before diagnosis. However, the aCD3 reactivity was already very low (10%) one year before diagnosis.
Conclusion. A severely depressed aCD3 reactivity is the first sign to herald progression towards AIDS in HIV-1 infected individuals.

Th.B.P.88

NEUTROPHIL RADICAL RELEASE AND LIPID PEROXIDATION IN HIV INFECTED PATIENTS

Jarstrand, Connie*; Carlin, G.**; Sönnerborg, A. and Åkerlund, B.***.
* Huddinge Hospital, Huddinge, Sweden; ** Pharmacia, Uppsala, Sweden; *** Roslagstull Hospital, Stockholm, Sweden.

Introduction. Since a transitory increase in Nitroblue tetrazolium (NBT)-reduction of neutrophils, reflecting an increased production of oxygen free radicals of these cells, has earlier been found during acute viral and bacterial infections a long term elevation in NBT-reduction was expected in the chronic HIV infected patient. Oxygen radicals are known to induce peroxidation of fatty acids occurring for example in cell membranes. A product of this process is malondialdehyde (MDA), which has been used extensively as a sign of lipid peroxidation.
Methods. Colourless NBT is reduced within the neutrophils by the superoxide anion to darkblue formazan which was measured spectrophotometrically. MDA was measured by a reversed phase liquid chromatography method.
Results. In 27 patients with the lymphadenophathy syndrom (LAS) the NBT reduction of resting neutrophiles was significantly higher than that of controls ($p <0.01$). Further, the plasma content of malondialdehyde in 22 patients with LAS or AIDS related complex was found to be higher than that in controls ($p <0.001$).
Conclusion. Radical production and resulting lipid peroxidation might contribute to the tissue damage and the premature ageing (Dorian Gray syndrome) seen in patients with HIV-infections.

Th.B.P.89

IMPAIRMENT OF POLYMORPHONUCLEOCYTE (PMN) CHEMOTACTIC AND BACTERICIDAL FUNCTION IN HIV-INFECTED CHILDREN

Roilides, Emmanuel; Mertins, S.; Eddy, J.; Venzon, D.; Walsh, T; Pizzo P. and Rubin, M.
National Cancer Institute, Bethesda, Maryland, USA.

Objective: HIV-infected children have an increased incidence of serious bacterial infections, which has been attributed to secondary abnormalities in immunoglobulins. Although PMN are the most important component of host defense against bacteria, PMN function in this group has not been assessed. Accordingly, we evaluated the functional activity of PMN from both asymptomatic [ASX] and symptomatic [SX] HIV-infected children.
Methods: PMN were obtained by standard techniques, from 7 ASX and 8 SX HIV-infected children, ages 6 mos to 11 yrs, prior to any antiretroviral therapy. Functional assays performed were: 1) chemotaxis to 10^{-8} M FMLP, 2) bactericidal activity against *Staphylococcus aureus* [S.A.] using a CFU assay, 3) superoxide [SO] generation following stimulation by 5 X 10^{-7} M FMLP, and 4) phagocytosis of S.A. and *Candida albicans* [C.A.].
Results: Chemotaxis: Chemotaxis of PMN from ASX children was uniformly decreased compared to controls (directed/random migration = 1.19 +/- .04 for ASX children vs 1.74 +/- .07 for controls (P_2=.0005), and increased in SX children (2.04 +/- .08, P_2=.028). Bactericidal activity: Killing of S.A. was defective in 5/7 ASX and 7/8 SX children (% reduction in colonies after 60 min. incubation = 56 +/- 4 for controls vs 42 +/- 6 for ASX children (P_2 = 0.034) and 29 +/- 9 for SX children (P_2 = 0.006). There was no correlation between presence or degree of bactericidal impairment and CD4 number or CD4/CD8 ratio. Serum from HIV-infected children did not inhibit the bactericidal activity of normal PMN. Preliminary data suggests that in vitro treatment with GM-CSF partially corrects the defect. SO generation: No abnormalities in SO production were found (nmol SO per 10^6 cells = 2.2 +/- .2 for controls, vs 2.0 +/- .3 for ASX and 2.4 +/- .5 for SX children). Phagocytosis: There were no abnormalities in phagocytosis of S.A (% of cells phagocytosing at 15 min = 62 +/- 8 for controls vs 57 +/- 5 for ASX and 67 +/- 7 for SX children) or of C.A. (66 +/- 4 for controls vs 66 +/- 9 for ASX and 66 +/- 4 for SX children).
Conclusion. Defects in both bactericidal activity and chemotaxis may contribute to the increased incidence of bacterial infections in HIV-infected children. Further study to define a potential role for GM-CSF in these patients is warranted.

Th.B.P.90

OXIDATIVE BURST ACTIVITY AND CELL SURFACE ANTIGEN EXPRESSION OF MONOCYTES FROM ASYMPTOMATIC HIV INFECTED INDIVIDUALS (AHI)

Landay, Alan*; Kessler, H.*; Benson, C.*; Phair, J.**; Rothberg, L.R.*; Spear, G.* et al. *Rush Medical Center, Chicago, IL and **Northwestern Medical Center, Chicago, IL. U.S.A.

Objective. To identify functional and phenotypic alterations of peripheral blood monocytes isolated from AHI.
Methods. Peripheral blood mononuclear cells were isolated on Ficoll Hypaque gradients. For oxidative burst measurements, cells were incubated with dichlorofluorescein-diacetate (DCFH-DA) and stimulated with phorbol myristate acetate (PMA), calcium ionophore (ION) or heat aggregated IgG (HAG). After stimulation, cells were stained with PE labeled anti-CD14 antibody. Shifts in green fluorescence which correspond to relative oxidative burst capacity of monocytes was measured by dual parameter flow cytometry. Expression of cell surface markers CD4, CD33, CD13 & HLA-DR on $CD14^+$ monocytes was also evaluated by dual parameter flow cytometry.
Results. Significantly lower oxidative burst activity was observed with monocytes from AHI compared to HIV negative donors stimulated with PMA (57.1 vs 90.3 relative fluorescence units, p=0.0001) and ION (59.1 vs. 96.7 units, p=0.0001). No significant difference was noted with HAG. The percentage of CD13 and CD33 monocytes was also significantly lower among AHI compared to HIV negative donors (86.6 vs. 95.9 for CD13, p=0.02; 92.1 vs. 99 for CD33, p=0.02).
Conclusions. Monocytes from AHI have significant alterations in function. These alterations may contribute to immunodeficiency and disease progression.

Th.B.P.91 STRATIFICATION OF HLA ALLOANTIGEN PRESENTING CELL FUNCTION IN PATIENTS WITH AIDS.

Landay, Alan*; Clerici, M.**; Kessler, H.* and Shearer, G.**. *Rush Medical Center, Chicago, IL and **Experimental Immunology Branch, NCI, Bethesda, MD, U.S.A.

Objective. To test the ability of peripheral blood mononuclear cells (PBMC) from patients with AIDS to serve as stimulating cells as well as alloantigen presenting cells (APC) to responding PBMC from HIV seronegative (HIV^-) donors.
Methods. HIV^-, unfractionated PBMC or PBMC depleted of monocytes (PBL) by plastic and nylon wool adherence procedures (<1% CD14+ cells) were stimulated in vitro with allogeneic PBMC from AIDS patients. The mixed lymphocyte reaction (MLR) was assessed by ^{3}H-thymidine incorporation and by interleukin 2 production.
Results. Our data indicate APC function of PBMC from AIDS patients can be stratified into three groups in which: (a) the MLR was normal irrespective of whether the HIV^-PBMC or PBL were used as responders (9/22, 41%); (b) the MLR was normal when HIV^- PBMC were used as responders but were defective when HIV^- PBL were used as responders (7/22, 32%); and (c) the MLR was defective irrespective of whether HIV^- responding PBMC or PBL were used (6/22, 27%).
Conclusions. These results suggest that AIDS patients can be stratified based on allostimulating and alloantigen presenting functions. This provides an approach for assessing monocyte (APC) function in AIDS patients as a potential indicator of drug efficacy in patients enrolled in therapeutic trials.

Th.B.P.93 VARIABILITY IN ISOTYPE-SPECIFIC IMMUNOGLOBULIN (Ig) SECRETING CELLS IN ASYMPTOMATIC HIV INFECTION

Spira,T.*; Lee,F.**; Nahmias, André**; Reimer,C.*; Bozeman,L.*; and Nesheim,S.** *Centers for Disease Control and **Emory University School of Medicine, Atlanta, GA, USA

Objective: To compare the relative number of circulating isotype-specific Ig secreting cells in asymptomatic HIV-infected and non-infected adults.
Methods: Peripheral blood mononuclear cells (PBMC) were assayed in 18 asymptomatic HIV infected and 19 negative adults. Isotype-specific Ig-secreting cells were enumerated with a reverse enzyme-linked immunospot assay using anti Ig $(Fab')_2$ as capture antibody, isotype-specific mouse monoclonal antibodies, and enzyme-labeled antimouse Ig. Wilcoxon rank-sum analyses were performed.

	No. Isotype-specific Ig secreting cells/10^6 PBMC (median)							
Results:	IgG_1	IgG_2	IgG_3	IgG_4	IgA_1	IgA_2	IgM.	Total*
Asymptomatic HIV	457	137	120	26	617	174	197	1941
Negative Controls	105	58	25	24	235	85	64	730
p value	<0.001	<0.01	<0.001	0.49	<0.001	<0.05	<0.01	<0.01

*IgD and IgE secreting cells were only detectable in 1 case

Conclusion: Significant differences were observed between asymptomatic HIV infected and non-infected adults for all of the isotype-specific Ig secreting cells (except for IgG_4). Other studies suggest that such increases are likely to be due to non-specific B cell proliferation whose mechanisms remain to be elucidated, as do the diagnostic and prognostic implications of such responses.

Th.B.P.95 Increased Spontaneous Release of CD8 Antigen from $CD8^+$ Cells Reflects the Clinical Progression of HIV-1 Infected Individuals.

F. Chu, P.H. Tsang, J.P. Roboz, J.I. Wallace and J.G. Bekesi. The Mount Sinai School of Medicine, New York, N.Y. 10029 USA

Associations were examined between selected phenotypic parameters, antibody response directed against HIV-1 and spontaneously released CD8 antigen (sCD8) in a cohort of 36 high risk HIV-1 (-) and 164 HIV-1 (+) homosexual males, 43 IVDA, 32 ARC and 36 AIDS patients, and 33 heterosexual controls. Marked increase in percent and absolute number of $CD8^+Ia^+$ (activated Ts) cells, effector Ts and $CD8^+$(Ts) cells was observed prior to detectable antibody directed against HIV-1. While the percentage of CD8 subsets did not decrease with the progression from HIV-1 (+) to AIDS, their absolute numbers did due to the progressive reduction in the absolute number of lymphocytes. The serum level of CD8 antigen was low at 235 U/ml in the heterosexual controls, increased significantly to 532 U/ml in the HIV-1(-) high risk group, further increased to 1069 U/ml in the HIV-1(+) population, to a high of 1374 U/ml in the HIV-1(+) IVDA individuals. This increase in the CD8 antigen level remained elevated as the patients progressed from symptomatic ARC (1555 U/ml) to AIDS (1354 U/ml). Furthermore, significant correlation was established between activated Ts ($CD8^+Ia^+$) cells, effector Ts subsets, $CD8^+$ cells and the increased spontaneous release of CD8 antigen, which is directly related to HIV-1 infection and the disease progression in AIDS.

Th.B.P.92 IN SITU DEMONSTRATION OF IL2 PRODUCTION IN LYMPH NODES OF HIV-1 POSITIVE PATIENTS WITH PGL.

Peuchmaur, Michel ; Emilie, D. ; Crevon, M.C. ; Delfraissy, J.F. ; Lemaigre, G. and Galanaud, P.
Hôpital Antoine Béclère and INSERM U. 131, Clamart, France.

Objective. Previous in vitro studies have demonstrated that HIV down-regulate the expression of IL2 gene. Using In Situ Hybridization (ISH) we studied in vivo IL2 mRNA expression in lymph nodes of Grade III (CDC) patients. The extent of this production should provide informations on the immunological status of such patients.
Methods. We investigated three HIV-1 positive patients with Persistent Generalized Lymphadenopathies (PGL). Formalin fixed and frozen tissue blocks were obtained immediately after lymph node biopsies. A three-steps immunoperoxidase technique was performed with monoclonal antibodies directed against HIV P24 protein and cellular antigens (CD3,4,8,25 and HLA-DR). The extent of HIV-RNA transcription and IL2 mRNA expression were estimated by ISH using respectively HIV gag RNA and IL2 RNA anti-sens probes.
Results. Histological examination demonstrated a HIV-related follicular hyperplasia. The interfollicular T-lymphocytes expressed CD3, 4 and 8 with a CD4/8 ratio >1. CD8 positive cells were observed in Germinal Centers (GC). A minority of interfollicular lymphocytes expressed HLA-DR and CD25. The presence of P24 and HIV RNA demonstrated active HIV replication in GC. The IL2-RNA probe hybridized with cells preferentially located in interfollicular areas. IL2 RNA expression was similar in HIV or non-HIV lymph nodes with follicular hyperplasia.
Conclusion. Contrasting with previous in vitro results, we show that in vivo IL2 production is not inhibited in hyperplastic lymph nodes replicating HIV.

Th.B.P.94 IMPAIRED IgM PRODUCTION AND MITOGEN-INDUCED SUPPRESSION OF IMMUNOGLOBULINS BY MONONUCLEAR CELLS FROM AIDS PATIENTS

Janoff, Edward N.*,**, Smith, P.D.* and Wahl, S.M.*
*National Institutes of Health, Bethesda, MD; **Veterans Administration Medical Center and University of Minnesota, Minneapolis, MN.U.S.A.

Purpose. To determine whether the inability of persons with AIDS to produce antibodies to new antigens, despite elevated levels of total immunoglobulins (Ig), is due to selective regulation of Ig classes.
Methods. We measured spontaneous and pokeweed mitogen (PWM) induced Ig production in vitro by peripheral blood mononuclear cells (PBMC) from 7 AIDS patients and 7 seronegative control subjects by ELISA, respectively.
Results. Spontaneous IgG and IgA were significantly higher for AIDS vs control PBMC (IgG:1230±145 vs 187±39; IgA:1444±183 vs 324± ug/ml, P<0.001), whereas IgM was less elevated (218±37 vs 75±21; P<0.02). Although PWM increased Ig production by control PBMC severalfold (P<0.01), it depressed the higher levels of production of all Ig classes by AIDS PBMC (P<0.01). These elevated spontaneous levels of IgG and IgA by AIDS PBMC were as high as PWM-stimulated levels by control PBMC. In contrast, the levels of both spontaneous and inducible IgM by AIDS PBMC were significantly lower than that of control PBMC (218±37 vs 2238±824 ug/ml; P<0.01).
Conclusions. Spontaneous production of IgG and IgA by AIDS PBMC greatly exceeds that of IgM and parallels that of PWM-stimulated control PBMC. The inability of AIDS patients to generate primary antibody responses to new stimuli may be due, in part, to depletion of the resting pool of IgM-producing B cells available to respond. Moreover, inhibition of Ig production by PWM suggests that stimulation in vivo may induce suppression of antibody responses.

Th.B.P.96 HIV AND BONE MARROW PROGENITORS PROLIFERATION

Pallavicini F.*, Antinori A.*, Tamburrini Enrica*, Candido A.**
*Clin. Malattie Infettive, **Serv. Ematologia-Università Cattolica-Roma-Italy

Objective: 1. To assess the proliferative capacity of granulocyte-macrophages progenitors cells (CFU-GM) from the bone marrow (BM) of AIDS patients and investigate the role of IL-1 and α-gp120 on this function; 2. to evaluate the effects of HIV-inactivated lysate (HIV-Lys) and conditioned medium obtained from culture of AIDS BM (HIV-BMCM) on the normal CFU-GM proliferative assay.
Methods: Bone marrow cells, obtained from 4 AIDS patients and 6 normal donor after informed consent, after depletion of adherent cells and T-lymphocytes, were tested in a proliferative assay using GCT-CM as a source of CSF. 30 U/ml of HIL-1; 1 μg/ml of HIV-Lys; 10% v/v of HIV-BMCM; 1 μg/ml of α-gp120 were used.
Results: The results are expressed as Δcpm (^{3}H TdR incorporation).

Normals	AIDS	AIDS +α-gp120	AIDS +HIL-1	Normals +HIV-Lys	Normals +HIV-Lys +α-gp120	Normals +HIV-BMCM
1201±610	267±135	173±57	227±154	-28±905	-12±169	1228±497

Conclusions: 1. The proliferative capacity of AIDS CFU-GM is depressed compared with normal control; this defect is unlikely due to a decreased IL-1 production; α-gp120 directly and/or indirectly inhibit the proliferation of HIV infected BM cells. 2. The severe impairment of proliferative capacity of normal CFU-GM exposed to HIV-Lys (but not to AIDS-BMCM) could suggest a role of viral proteins; α-gp120 could contribute to impaired CFU-GM proliferation.

Th.B.P.97 STUDIES ON THE IN VITRO SECRETION OF HIV1 SPECIFIC ANTIBODIES BY *PERIPHERAL BLOOD CELLS* FROM HIV1 INFECTED SUBJECTS.

Vendrell, J. P.**, Corbeau, P.*, Ducos, J.**, Reynes, J.***, Huguet, M.F.*, Serre, Arlette**, Cannat, A.*.
* INSERM U65, ** Laboratoire d'Immunologie, Hôpital Lapeyronie, ***Service des Maladies infectieuses, Hôpital St Eloi, MONTPELLIER, FRANCE.

PBMC from 114 HIV1 seropositive subjects (73 asymptomatic, 15 ARC, 26 AIDS) and from 30 HIV1 negative controls were incubated : a) in the wells of the ELAVIA kit (Pasteur) : the HIV1 antibodies secreted in vitro and fixed on the antigens were revealed by the use of a low noise enzymatic complex, b) in antigen free conditions : the supernatants were tested instead of PBMC by the same amplified ELISA technique or submitted to Western blot analysis on nitrocellulose strips from commercial kits.

RESULTS. a) Positive results were observed in all cases with the PBMC of HIV1 seropositive subjects and in none with the control PBMC, b) Positive results correspond to an active secretion and not to a release of passively adsorbed seric antibodies, c) Active secretion is antigen and mitogen independent and occurs within 18 hours' incubation, d) The capacity for in vitro antibody production is a continuous and not a transitory phenomenon in seropositive subjects as opposed to classical models of immunization, e) Cells corresponding to all HIV1 specificities may be present in the blood stream of HIV1 infected subjects and the env-encoded gp bands are always present in both PBMC supernatant and serum Western blots, f) When supernatant and seric patterns differ the decline of gag-encoded p antibodies is always more profound in the supernatant than in the serum.

CONCLUSIONS. The continuous capacity of in vitro HIV1 antibody production seems to be an important feature of HIV1 infection. The detection of such cells could prove useful for the follow up of subjects at risk and of neonates.

Th.B.P.98 ENHANCED ENDOGENOUS TNFα PRODUCTION IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF HIV-1 INFECTED PATIENTS.

Rossol S., Voth R., Brunner S., Klein K., Büttner M.**, Möller W.E.G.*, Meyer zum Büschenfelde K.H. and Hess G.
I. Med. Klinik und Poliklinik und * Physiologisches Institut der Johannes Gutenberg Universität Mainz, ** Veterinärmed. Institut der Universität München.
FEDERAL REPUBLIC OF GERMANY.

OBJECTIVE: To study the role of TNF-α in HIV-1 infected patients.

METHODS: Blood samples positive for HIV-1 were obtained from 150 patients at various stages of disease. Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll-Paque and stimulated with various inducers for TNFα production. TNFα was quantified by using a highly sensitive ELISA.

RESULTS: It turned out that corynebacterium parvum was the most potent inducer of TNFα when compared to classical inducers such as various preparations of LPS or Sendai virus. In a group of 56 healthy donors mean level of endogenously produced TNF yielded in 10.2 ng per ml. However patients at stage 2 (CDC) or 3 to 4 were able to produce up to 28 ng of TNF when stimulating their lymphocytes with 140 µg per ml of corynebacterium parvum. In all groups of patients and in healthy donors TNFα production was absent when PBMC were coincubated with PGE_2.

CONCLUSIONS: Our data suggest that PGE_2 plays a major role in regulating TNFα secretion. Enhanced TNF levels in patients with HIV infection may account for patients development of cachexia, fever and show monocyte dysregulation early in HIV-1 infection.

Th.B.P.99 NORMAL AND HIV ASSOCIATED FUNGICIDAL ACTIVITY OF MONOCYTES

Tamburrini Enrica*, Antinori A.*, Morace G.**, Manzara S.**, Ortona L.*
*Ist. Clin. Malattie Infettive, ** Ist. Microbiologia-Università Cattolica-Roma-Italy

Objective. i) to evaluate the ability of monocytes (M) and monocyte-derived macrophages (m-dM) of AIDS patients to kill *Candida albicans* and the role of rIFN-γ in their activation, and ii) to study the effect of HIV-lysate (HIV-lys) on M and m-dM fungicidal activity in healthy individuals (normals).

Methods. Ten AIDS patients and 9 normals were studied. Cell monolayers (0.25×10^6/well), untreated or treated with 300U/ml of rIFN-γ, 0.4 µg/ml of HIV-lys, 1 µg/ml of anti-gp120) were challenged with 0.1 ml of *C. albicans* (10^3 CFU/ml) for 2 h.. The killing activity was expressed as % reduction of *C. albicans* CFU.

Results. AIDS M killing was impaired (31.6±13.5 vs 48.7±9.8; $p<0.005$) and partially restored by rIFN-γ (35.5±12.7); AIDS m-dM killing was slightly reduced (46.9±12.7 vs 57.8±7.4). HIV-lys resulted in heterogeneous reduction of activity by normal M, but not m-dM; the defect was not overcome by anti-gp120.

Conclusion. i) M, but not m-dM, killing was impaired in AIDS; different killing systems could be operative in M and m-dM; oxidative and non-oxidative mechanisms could be involved; rIFN is one of, but not the only, factor required to induce M effector reactions (IL-2 or GM-CSF as cofactors?). ii) HIV-lys can induce AIDS-like defect in normal M but not in m-dM; a role of envelope proteins (gp41 but not gp120) could be suggested.

Th.B.P.100 AUGMENTATION DE LA PRODUCTION DE RADICAUX LIBRES DE L'OXYGENE PAR LES PHAGOCYTES DU SANG CIRCULANT DES MALADES INFECTES PAR LE VIRUS HIV-1.

Vuitton, Dominique A. ; Didier, J.M. ; Vuillier, J. ; Bertrand, M.A. ; Drobacheff, C. et la "Cellule SIDA du C.H.U. - Franche-Comté".
Centre Hospitalier Régional et Universitaire, F-25030 Besançon, France.

Objectif. Apprécier, par l'étude de la chimioluminescence, la production de radicaux libres de l'oxygène par les phagocytes du sang au cours de l'infection par HIV.

Méthodes. La chimioluminescence (CL) des cellules du sang dilué au 1/10e et au 1/100e a été mesurée en présence de luminol et de lucigénine chez 37 sujets HIV+ avant traitement par zidovudine (23 des groupes II et III, et 14 du groupe IV), à l'état basal et après stimulation par Con A, f-Met-Leu-Phe, phorbol myristate acetate, latex et zymosan, exprimée en intensité lumineuse (IL) par 1000 phagocytes et en IL stimulée/IL basale, et comparée à celle obtenue chez 35 sujets témoins sains appariés pour l'âge.

Resultats. La CL des phagocytes des malades HIV+ était très significativement supérieure à celle observée chez les témoins quel que soit le réactif utilisé et tant à l'état basal qu'à l'état stimulé ($p<10^{-4}$). Cette différence reposait principalement sur une hyperactivation basale des phagocytes, qui n'était pas significativement différente dans le gr.IV comparé aux gr.II et III ; la sensibilité aux différents stimulus utilisés était diminuée. Il n'existait pas de relation entre la CL et l'existence d'une complication clinique particulière ou le nombre de lymphocytes circulants.

Conclusion. L'hyperproduction de radicaux libres de l'oxygène par les phagocytes contraste avec la diminution rapportée d'autres fonctions phagocytaires chez les malades HIV+. La responsabilité des monocytes et des polynucléaires dans ces modifications et l'analyse séquentielle de la CL chez ces malades sont en cours d'étude.

Th.B.P.101 REFRACTORINESS OF B CELLS TO REGULATION BY LGL IN HIV INFECTION.

Gloria Echeverría de Pérez, L. Deibis, R. Ramírez, Z. Rios, M. de Márquez, I. Blanca and N. E. Bianco.
Clinical Immunology National Center (WHO/SAS/UCV), Caracas Venezuela.

$CD3^-$, CD16+ large granular lymphocytes (LGL) behave as helper cells of Immunoglobulin (Igs) synthesis by peripheral blood lymphocytes (PBMC), as measured in culture supernatants by ELISA. We evaluated such capability in 21 HIV+ individuals (11 of group II and 10 with AIDS), 12 HIV negative homosexuals (HM) and 11 heterosexual controls. Spontaneous Igs levels were significantly higher in HIV+ when compared to HM or controls (1812 and 1553 vs. 432 and 425 ngs/ml). PBMC (1.25×10^5), co cultured with increasing amounts of autologous LGL (5 and 7.5×10^4) in the presence or absence of PWM (1/200), caused no further enhancement of Igs synthesis in HIV+, while values in both HM and controls were significantly increased (2000 and 1560 vs 620 and 710). Antibodies to gp120, gp41 and p24 were detected by western blot in culture and cocultured supernatants from HIV+ individuals. We suggest that B cell function in HIV infection is resistant to regulatory signals not only from T cell but also from LGL.

Th.B.P.102 ACTIVATED T-CELLS (TC) AND HUMAN IMMUNODEFICIENCY VIRUS (HIV) PROGRESSION

Freeman, Theodore; Boswell,R.N; Hensley,R.E.; Butzin,C.
US Air Force HIV Program, Lackland AFB, San Antonio, Texas, USA.

Hypothesis: HIV is a retrovirus (RV) trophic for CD4+ cells. Proliferation of RV requires the translation and transcription of the host genome and cellular activation. Activation of TC should correlate with progression of HIV infection. One marker of TC activation is the production of HLA class II (DR) antigens (AG) which are not present on resting TCs, but are elaborated within 24-48 hr after activation.

Methods: OKIa marks class II antigens. When quantitating lymphocytes by flow cytometry the value OKIa minus CD20 (a pan-b-cell marker & all b-cells have class II AG) should represent activated TCs (i.e. a OKIa+/CD20-population).

Results: Examination of available data on the >700 cases of HIV positive patients in the WHMC HIV data base shows: 1)patients with >25% TCs consistently had initial activation values of 10.3 while those who had decreased TCs had values of 12.0 ($P<.001$). 2) Pts with absolute CD4 counts consistently >400 had values of 11.5 while those with <400 had values of15.9($P<.001$) 3) Walter Reed (WR) stages 1 or 2 without progression at 1-2 yrs had values of 11.4 while those progressing to WR3-6 had values of 14.8($P<.001$).

Conclusion: These data suggest that activation of TCs as measured by OKIa+ CD20- cells correlates with HIV disease progression. We are aware that the activated TCs may, in fact, be CD8+ cells (Ziegler-Heitbrock et al.JCI.8(6) 4783,1988) and prospective studies to elucidate which TC subpopulation is activated in our patients are in progress.

Th.B.P.103 DECREASED LYMPHOCYTE PROLIFERATION TOWARDS POKEWEED MITOGEN APPEARS AS A VERY EARLY MARKER IN HIV INFECTION.

K. Huygen[1], Y. Fairon[2] and P. Henrivaux[2].
1 : Instituut Pasteur van Brabant, 1180 Brussels
2 : CHU-Sart Tilman (Internal Medicine - HEMATOLOGY), State University of Liege Belgium

Objective. To assess the immune function among HIV infected patients regarding the clinical stage of disease.
Methods. Using a whole blood assay, we have examined thirty-six HIV+ subjects for their in vitro lymphoproliferation towards Phytohaemagglutinin (PHA) and Pokeweed mitogen (PWM), and for their interferon production following stimulation with Newcastle Disease Virus (IFN-α) and PHA (IFN-γ).
Results. Decreased proliferation and IFN production were observed in a number of patients and this number increases with disease progression :

Patients (#)	IFN-α	IFN-γ	PHA	PWM
Healthy carriers (10)	10 %	20 %	0 %	42 %
Lymphadenopathy (6)	40 %	50 %	0 %	71 %
ARC (17)	40 %	35 %	23 %	76 %
AIDS (3)	33 %	33 %	33 %	100 %

Conclusions. Decreased proliferation to PWM was the earliest and most pronounced immune defect, already observed in 42 % of the HIV+ healthy carriers. Next, decreases in IFN-α and IFN-γ production were observed in about 40 % of the patients with lymphadenopathy. Decreased proliferation to PHA finally was the last parameter to decrease in patients with ARC and with full-blown AIDS. Decreased responses to PWM correlated to low OKT4/OKT8 ratio's (<0,5).

Th.B.P.104 IN VITRO B CELL DIFFERENTIATION IN NORMALS, rGP160 VACCINATED VOLUNTEERS, AND HIV+ SUBJECTS

Reuben, James*; Liang, L.*; Li, S.*; Greenberg, S.** Smith, G.***; Couch, R**.
*Univerity of Texas, M.D. Anderson Cancer Center, and the **Baylor College of Medicine, Houston, TX, and ***MicroGeneSys, Inc., Westhaven, CT, USA.

Objective. To determine B cell differentiation to HIV.
Methods. Peripheral blood mononuclear cells from asymptomatic HIV+ (SF), normals (HIV-) and rGP160 vaccinee subjects were cultured on days 0, 14, 28, 44, and 194 post-vaccination with rGP160 antigen or HTLV-IIIB virus for 7 days at which time, supernatants were harvested and assayed for IgG by ELISA.
Results. A significant IgG production is defined as that which exceeded the mean + 95% C.I. of normal donors.

Group	No. of Responders (%) for IgG Production to HIV	
	HTLV-IIIB	rGP160
Normal (HIV-)	5/23 (22)	1/15 (7)
rGP160 placebo	2/5 (40)	1/5 (20)
rGP160 vaccinees	3/5 (60)	4/5 (80)
HIV+(SF)	4/4 (100)	3/3 (100)

Conclusion: B cells from rGP160 vacinees and HIV-infected subjects can produce IgG when stimulated with IIIB virus or rGP160 antigen suggesting the existence of a circulating memory B cell.

Th.B.P.105 USEFULLNESS OF LYMPHOBLASTIC TRANSFORMATION TEST (L.T.T.) IN ASYMPTOMATIC PATIENTS (II AND III STATUS OF CDC CLASSIFICATION).

Claude BEUSCART*, A. COGET, B. SIVERY, O. LEROY, Y. MOUTON, A. FOURRIER.
CISIH - NORD - C.H. TOURCOING - FRANCE.

Objectives : Evaluation of Lymphoblastic Transformation Test (L.T.T.) in asymptomatic HIV positive patients.
Methods : For 74 clinically asymptomatic or with chronical lymphadenopathy patients, having a 18 months follow-up, a LTT (phytohemagglutinin, pokeweed, concavanalin A) was undertaken every 6 months.
Results : This test was disturbed (reactivity less than half of control's values), for 45 patients. 28 had a disturbed test from the first examination, in 17 cases the modification of the LTT appeared during the course of the disease.

LTT	Clinical stability II or III status	Clinical aggravation to IV status
Always normal	27	2
Always abnormal	23	5
Appearance of decrease	11	6

When the LTT decreased, there was a more frequent worsening towards the IV status (χ^2 = 4.78 ; $p < 0.05$). Moreover, the appearance of this abnormality preceded for several months the appearance of clinical signs of severe immunodepression (6 cases/8).
Conclusion : For asymptomatic patients the paraclinical exams should be restricted, nevertheless the LTT seems to be an early predictive test of the worsening to IV status (correlated with usual test like beta2microglobulin, ESR..)

Th.B.P.106 IMPACT OF 3'-AZIDO-3'-DEOXYTHYMIDINE (AZT) ON THE IN VITRO IMMUNOGLOBULIN SECRETION IN A POKEWEED MITOGEN-DRIVEN CELL SYSTEM.

Tauris, P.*; Petersen, C.M.*; Møller, B.* and Black, Finn T.**
*Dept. of Clinical Immunology, the Tissue Typing Laboratory, **Dept. of Internal Medicine and Infectious Diseases, University of Aarhus, Aarhus, Denmark.

Objective. To study the impact of AZT on replication and Ig-secretion in in vitro-cultures of HIV-positive and -negative subjects.
Methods. Proliferation and distribution of surface markers was assessed by the ^{3}H-thymidine technique and flow-cytometry. Ig-secretion was monitored with the protein-A plaque-forming cell assay.
Results. In HIV-negative, concentration of 0.2-1.0 ul/ml of AZT severely decreased T- but not B-cell proliferation while distribution of surface markers was unaltered by AZT. A severe decrease in Ig-secretion in AZT-supplemented cultures was found. In HIV-positive, the already decreased responsiveness to mitogen activation was unaltered by AZT.
Conclusion. The AZT-effect on peripheral blood lymphocyte proliferation and Ig-secretion is mediated through T-cells. The AZT-impact on the functions of peripheral T- and B-cells should be taken into consideration when dose-regimens are planned in clinical trials.

Th.B.P.107 INHIBITION OF LYMPHOCYTE PROLIFERATION INDUCED BY MICROBIAL ANTIGENS IN HIV INFECTED INDIVIDUALS

Victorino Rui; Maria V.A.J. and Pinto L.A..
Faculty of Medicine of Lisbon - Department of Medicine 2, Av. Prof. Egas Moniz, 1600 Lisbon, Portugal.

Patients with HIV infection have depressed cell mediated immune responses to microbial antigens. We did 20 studies in HIV seropositives subjects and in 25 normal individuals to assess lymphocyte responses in vitro to four different Antigens (Tetanus Toxoid-TT, Escherichia Coli-EC, CMV and Toxoplasma Gondi-TG) as part of a study to assess prognostic factors. Lymphocyte responses to the Antigens in vitro were assessed by quantitating ^{3}H Thymidine incorporation in peripheral blood lymphocytes and positive responses were considered when the stimulation index was $\geq$ 2. About two thirds of the normal subjects had significant responses to E.C. and T.T.. This contrasts with HIV infected subjects (50% persistent generalized lymphadenopathy 25% AIDS related complex and 15% AIDS) where a major difference between E.C. and T.T. was found: one third responded to E.C. and none to T.T.. The detailed analysis of the cpm of the in vitro cultures revealed that a significant proportion (40%) of HIV + subjects had levels of lymphocyte proliferation in the presence of the antigens which were at least 50% lower than the ones recorded in the absence of Ag. This phenomenon is compatible with a suppression of lymphocyte proliferation induced by the Antigens and warrants further analysis in prognostic terms and in relation to its immunological and clinical significance.

Th.B.P.108 ESTIMATION OF BEST ABSOLUTE CD4 COUNT FROM MULTIPLE PAIRINGS IN TWO-COLOR FLOW CYTOMETRY

Transfusion Safety Study Group* represented by Niland, Joyce C.**
*Participating institutions in New York City, Miami, Detroit, Seattle, San Francisco, and Los Angeles
**City of Hope National Medical Center, Duarte, California, USA

Objective. To evaluate 2 methods of estimating the absolute CD4 count when different values are obtained due to more than 1 pairing with other monoclonals.
Methods. In a longitudinal observational study of transfusion-associated HIV-1 infection, immunologic phenotyping is performed by two-color flow cytometry using a panel of 11 antibody pairs. CD4 antibody is paired with 3 others [CD8, CDw29 (4B4), and CD45 (2H4)]. In the CD8 pairing CD4 is conjugated with RD-1; in the other 2, with FITC. Each pair gives a significantly different mean absolute CD4 count, such that the best single CD4 is not known. To maximize available information in estimating CD4, 2 algorithms were evaluated: 1) the median of the 3 values (the mean or the single value if 1 or 2 values are missing); 2) the CD4 value closest to the CD2 count minus the median CD8 count, assuming that the sum of CD4 and CD8 staining cells should be close to the total T-cell count.
Results. Relative to the second algorithm, the first provides a CD4 estimate for a larger number of subjects, results in fewer outlying values, and gives more consistent values for the same subject through time.
Conclusion. Although the second algorithm takes into account information regarding other lymphocyte subsets, the algorithm using the median produces more stable trends over time for any given subject.

(Sponsored by Contract No. NO1-HB-4-7003 of the National Heart, Lung, and Blood Institute.)

Th.B.P.109 IDENTIFICATION OF MULTIPLE HIV-1 CORE PROTEINS ON WESTERN BLOTS BY A MONOCLONAL ANTIBODY

Liang, Chi-Ming; Henry, S. and Epstein, J.S.
Center for Biologics Evaluation and Research, FDA, Bethesda, MD, USA

Objective. To characterize the HIV-1 core proteins on Western blots
Methods. Female BALB/c mice were immunized with partially purified HIV-1 proteins. Hybridomas secreting monoclonal antibodies (mAbs) were produced by fusing P3X63Ag8 653 myelomas with the splenocytes of the immunized mice and screened by enzyme-linked immunosorbent assay. The positive hybridomas were cloned and the mAbs were examined by Western blots.
Results. A novel mAb against HIV-1 core proteins was produced. The mAb, namely CBER-4, was of IgG1 subclass. Unlike our other anti-HIV-1 core protein mAbs which reacted with only one or two proteins in Western blot, this mAb recognized multiple bands. It bound to p13, p15, p21, p24, p28, p29, p32, p39, p49, p55 on the Biotech/Du Pont Western blot strip and p21, p24, p28, p29, p39, p49, p55, p68, p80, p96, p110 on Bio-Rad strip. The binding was specific as the mAb, unlike positive control serum, did not bind to myristylated core protein (p17), or envelope proteins (p41, p120, p160) nor to tat protein (p14) or transcriptase (p51, p66). Moreover, the mAb did not react with HTLV-1 in ELISA nor bind to any proteins in HTLV-1 Western blot.
Conclusion. Besides p24 and p55, multiple protein bands were recognized in Western blot by a mAb directed against HIV-1 core proteins, indicating that these proteins are derived from HIV-1 core proteins and share the same epitope. This mAb will be useful for characterizing and comparing HIV-1 Western blot strips from different manufacturers or sources.

Th.B.P.110 EVALUATION OF SENSITIVITY AND SPECIFICITY OF SYNTHETIC PEPTIDE AND RECOMBINANT BASED ANT-HIV1&2 EIA

Joller H.I.
University Hospital, Zurich, Switzerland

The first generation of anti-HIV screening assays, introduced shortly after the discovery of HIV, were based on virus lysate. They did thus react to all antibodies directed towards various proteins in the HIV1, but cross-reacted also to impurities in the cell line. To overcome problems of cross-reactivity and to enable recovery of lower concentrations of anti-HIV EIA:s based on recombinant produced antigen and synthetic peptides have been developed. It is, however, important that the improved specificity not results in a decreased sensitivity, i.e. antibodies recognized by the assay are produced by all HIV-infected including also the recently discovered HIV2. We have evaluated a new anti-HIV test system (Pharmacia Diagnostics AB, Sweden) based on synthetic peptides, directed towards the transmembran associated anti-HIV1 and -HIV2 respectively and recombinant produced P24. The tests are available as combined, HIV1&2 envelope and HIV1&2 envelope/core assays for screening, and as separate assays for differentiation. In a panel of 150 sera obtained from HIV-infected patients, all were found to produce anti-envelope detectable by the 2 screening and the separate HIV1 assays. Half of the AIDS patients and 2/3 of the ARC and asymptomatic patients produced detectable amounts of anti-P24 for the differential assay. The crossreactivity was evaluated in a panel of 100 sera drawn from patients with SLE, HPV, CMV, RA and Tumors. In the envelope assay 7 sera were repeatedly positive, and 4 borderline. Two sera were found to be confirmed HIV1-positives and their absorbances values were >2.000 while those 5 cross-reacting sera had absorbances markedly lower. In the envelope/core assay 8 sera cross-reacted; 2 of them with single P24-band. The cross-reacting sera were from patients with SLE, HPV, Myeloma and Sklerodermi. It can be concluded that all our HIV-infected patients produced anti-HIV detectable by both screening assays. The differential tests enables a separation of the positive reply. In a selected panel of sera from patients with conditions known to cross-react in these assays 2 correct positives were found and 2 with P24-activity, and the rate of false positives thus 5%.

Th.B.P.111 DEVELOPMENT OF A METHOD FOR CORRELATING THE PRESENCE OF HIV ANTIGEN AND PROVIRUS

Paul, David B.*; Bankowski, M.*; Kuhns, M.**; McNamara, A.**; Landay, A. L.* and Spear, G. T.*
*Rush University, Chicago, Ill., USA, **Abbott Laboratories, North Chicago, Ill., USA

OBJECTIVE: a) To develop a sensitive flow cytometric assay that will allow detection of HIV antigen containing cells. b) To correlate the presence of HIV antigen with provirus in cells.
METHODS: Cell lines were fixed, permeablized, and stained for HIV antigens with a variety of fluorescent antibodies. After staining, fluorescence was quantified by flow cytometry. In some experiments, populations of infected and uninfected cells were mixed and stained, and the positive and negative populations identified using the flow cytometer. The detection of provirus in fixed cells was accomplished by DNA amplification, using the polymerase chain reaction (PCR) and a liquid phase molecular hybridization system.
RESULTS: We compared 3 antibody systems: biotinylated IgG from AIDS patients; affinity purified rabbit anti-p24, and a monoclonal antibody against p24, each with an appropriate secondary reagent. All 3 systems enabled detection of HIV infected cells. The monoclonal antibody had the greatest sensitivity for detection of infection in cells, as shown by increased fluorescence over control antibodies or uninfected cells. Provirus was detectable by PCR in fixed and stained cells. This technique is appropriate for use in flow cytometric separation of cells into positive and negative populations and will allow analysis for provirus by PCR.
CONCLUSIONS: The anti-p24 monoclonal antibody allowed highly sensitive detection of cells containing p24. Analysis by PCR, followed by liquid phase molecular hybridization, confirmed the HIV provirus was detectable after fixation. This method will prove useful in determining the correlation between the presence of p24 and the provirus in cells from HIV infected individuals.

Th.B.P.112 HUMAN IMMUNODEFICIENCY VIRUS (HIV) EXPRESSION AND ANTIGENIC STABILITY OF HIV-INFECTED CELLS FOR USE IN FLOW CYTOMETRIC IMMUNOFLUORESCENCE ASSAY (FIFA).

Sligh, Julie M., Roodman, S.T., Knutsen, A.P., Tsai, C.C.
St. Louis University School of Medicine St. Louis, MO, USA

The Flow Cytometric Immunofluorescence Assay (FIFA) detects antibodies to Human Immunodeficiency Virus (HIV) with high sensitivity and specificity compared to ELISA and Western blot (WB). The FIFA is an indirect immunofluorescence assay that uses live HIV-infected H9 cells (HIV-H9) and is analysed by flow cytometry. Flow cytometric interpretation is more objective than WB, which makes FIFA an alternate confirmatory assay for the presence of anti-HIV antibodies. Since use of live HIV-H9 cells presents a potential biohazard, a method is presented to eliminate viral infectivity while preserving viral antigenicity on the cell surface. The AMT-treated cells were completely inactivated for viral infectivity as measured by coculture with uninfected target H9 cells using FIFA and reverse transcriptase assays. Viral antigens present on the cell surface of HIV-H9 cells were characterized using monoclonal and polyclonal antibodies to specific subunits of HIV. AMT-inactivated HIV-H9 cells expressed viral antigens at approximately 70% of the level of untreated infected cells. The inactivated cells are stable for up to two days when stored in high serum concentration or in the presence of protease inhibitors. AMT-inactivated HIV-H9 cells are ideal for FIFA since the cell membrane integrity and viral antigenicity are maintained and the biohazard of viral infectivity is eliminated.

Th.B.P.113 IMMUNODOSAGE TYPE ELISA DES ANTIGENES MEMBRANAIRES CD4 ET CD8 DE LYMPHOCYTES PROVENANT DE SUJETS SAINS OU INFECTES PAR LE VIRUS HIV.

Carrière, Dominique*; Fontaine, C.*; Rabesandratana, H.**; Serre, A.**; Vendrell, J.P.**; Andary, M.**; Clot, J.**; Brunet, C.***; Sanpol, J.***; Lagrange, M.C.*; Paolucci, F.* et Pau, B.
*Sanofi Recherches, Montpellier, France; **C.H.U. La Peyronie, Montpellier, France; ***C.H.U. La Thymone, Marseille, France.

Méthodes. Un dosage de type ELISA simple, sensible et rapide permettant la détermination des molécules CD4 et CD8 des lymphocytes T a été standardisé et les résultats ont été comparés à ceux de la méthode d'analyse par cytométrie en flux. Le dosage est réalisé en plaque de microtitration, en une seule étape (20 min.) permettant : ■ l'immobilisation des cellules par des anticorps monoclonaux pan-T adsorbés sur le plastique, ■ le marquage simultané des antigènes par des anticorps anti-CD4 ou anti-CD8 couplés à la peroxydase.
Résultats. Les résultats sont exprimés en concentration picomolaire (pM) d'antigènes, grâce à des courbes standard déterminées à partir de puits de dosage calibrés en CD4 et CD8 (molarité). Les valeurs du CD4 des échantillons sanguins de sujet HIV$^-$ (séro-négatifs) (n=22), HIV$^+$ (n=44) et SIDA (n=22) sont respectivement 40,5 ± 15,4 pM, 21,7 ± 11,6 pM et 7,9 ± 4,9 pM. Les concentrations du CD8 ne sont pas significativement différentes dans ces trois groupes. La corrélation entre les concentrations du CD4 mesurées par notre méthode et le nombre de cellules CD4$^+$ mesurés par la cytométrie en flux est significative (r=0,92, n=34).

Th.B.P.114 SIMPLE LABORATORY TESTS AS MARKERS FOR THE VARIOUS CLINICAL MANIFESTATIONS OF HIV INFECTION.

Greco, Dirceu B., Paulino, U.H.M., Adams, I., Vitoria M.A.A., Praça, C.L., Castro, C.C. et al.
Immunodeficiency Clinic, Infectious and Parasitic Diseases Service, Faculty of Medicine, Federal University of Minas Gerais, Belo Horizonte, Brazil.

Objective: To study the correlation between laboratory tests and clinical manifestations of HIV infection.
Methods: From February 86 to May 88 we have evaluated 549 individuals who spontaneously came to the clinic due to risky behaviour, with symptoms of HIV infection or anxiety related to the AIDS epidemic. One hundred sixty eight (30.6%) had ELISA repeatedly positive for HIV 1 and 380 were not infected(NI). Among the infected, 60 were asymptomatic(As) and the remaining 105(64.8%): 23 with PGL, 50 ARC and 32 AIDS. Three simple laboratory tests(absolute lymphocyte count, ESR and delayed skin tests: PPD, Candida, SK-SD and trichophyton) were used to evaluate all individuals.

Results: in percentage	NI	As	PGL	ARC	AIDS
Lymphopenia(1,500/mm3)	7.0	7.7	9.5	26.1	60.7
ESR (< 20 mm)	17.0	17.0	16.7	70.0	88.2
(< 100 mm)	1.6	2.1	0	12.5	30.4
Cutaneous anergy	11.0	27.1	38.9	62.8	66.7

Conclusion: These are simple tests , easy to perform, readily available, inexpensive and they have showed a positive correlation with the clinical presentation of HIV infection. We believe that if repeated at fixed intervals they may help in the evaluation of disease progress.

Th.B.P.115 COMPARISON OF THE SIMULTANEOUS ADMINISTRATION OF INTRADERMAL (ID) AND MERIEUX MULTITEST CMI (MM) SKIN TEST METHODS IN HIV1 SEROPOSITIVE PATIENTS.

Mayers, Douglas*, Goodman, DL*, Wagner,KF**, and Ebbeling,WL*. *National Naval Med. Center, Bethesda, MD, **Henry M Jackson Foundation,Rockville, MD, U.S.A.

Objectives. To compare skin test results using the ID method with results from the MM method using individual patients (pts) as their own controls.
Methods. Skin tests were applied simultaneously to the volar surfaces of both forearms on 60 HIV1 seropositive patients. The ID panel was placed on the right forearm and consisted of tetanus(T) 1:10, candida(C) 1:10, mumps (M) 0.1 ml, trichophyton(Tr) 1:30, and PPD(TB) 5TU. The standard MM panel of T, diphtheria(D), strep(S), tuberculin, control(Ctr), C, Tr, and proteus (P) was placed on the left arm. All results were read at 48 hours. Positive was ≥5 mm for ID and ≥2 mm for MM.
Results. Individual Test Comparisons

Merieux POS NEG	Tetanus		Candida		Trichophyton		Tuberculin	
I POS	36	3	43	21	14	10	1	0
D NEG	1	20	1	3	3	41	5	62

Intradermal Skin Tests and (Merieux Multitest CMI) % Positive Vs T4 Count

T4 Count	N	T	C	Tr	TB	M	Ctr	D	S	P
> 400	36	69(67)	94(72)	33(31)	0(14)	81	(0)	(44)	(25)	(44)
200-400	25	48(48)	96(68)	40(24)	0(0)	44	(0)	(36)	(0)	(20)
< 200	7	29(14)	86(14)	29(0)	14(14)	43	(0)	(14)	(14)	(0)

Conclusions. For T4> 200, MM and ID showed similar results with ID more reactive. All pts with T4< 200 were on AZT. 6/7 of these pts had increased reactions from previous ID results. AZT may modify DHS for ID > MM.

Th.B.P.117 ANTIBODIES TO SULFAMETHOXAZOLE (SMX) IN NORMAL, ALLERGIC, HIV INFECTED, AND AIDS PATIENTS

Sullivan, Timothy J., Davidson, R., Budens, R. and Nightingale, S
University of Texas Southwestern Medical Center, Dallas, Texas, U.S.A.

Objectives. To establish assays for antibodies to sulfonamides. To determine the prevalence of IgG, IgA, IgM, and IgE antibodies to SMX in the blood of normal control subjects, SMX allergic patients, and randomly selected HIV+ and AIDS patients. To identify univalent haptens capable of inhibiting antibody binding to SMX haptens on carrier molecules.
Methods. SMX was coupled to human serum albumin (HSA) or to histidine (HD) and a variety of other low MW molecules in the N^4-sulfonamidoyl configuration. SMX-HSA was used in RAST assays for IgE and ELISA assays for IgG, IgA, and IgM. Penicillin (penicilloyl) substituted HSA (P-HSA) was used in an IgG ELISA. Specificity was verified by demonstrating inhibition of binding with free SMX-HSA and SMX-HD (univalent hapten), but not with HSA or P-HSA.
Results.

Subjects	No.	Isotype Positive					(%)
		IgG	IgA	IgM	IgE	Any+	
Normal	10	0	0	0	0	0	(0%)
Allergic	38	10	13	3	14	23	(61%)
HIV+	51	47	13	20	4	48	(94%)
AIDS	17	12	6	4	2	15	(88%)

In marked contrast to the high prevalence of Ig to SMX, only 3 (6%) HIV+ and 0 AIDS patients expressed IgG to P-HSA. SMX-HD (1 mM) added at the time of serum addition to ELISA plates inhibited Ig binding to the solid phase 34%-98%. Other univalent haptens studied, and free SMX, also inhibited binding, but less efficiently.
Conclusions. Antibodies to SMX were detected in the majority of AIDS, HIV+, and SMX allergic patients. These data suggest that there may be an immunologic basis for many adverse reactions to SMX in AIDS patients. Hapten inhibition of Ig binding was shown to be feasible in vitro, suggesting the possibility that hapten inhibition could be developed as a strategy to suppress clinical allergic reactions to SMX.

Th.B.P.119 THE EFFECT OF VACCINATION AGAINST HEPATITIS B ON THE CD4+ CELL COUNT IN ANTI-HIV POSITIVE MEN.

Gutfreund,Klaus*;Cheetham-Speth,D.**;Rossol,S.*;Voth,R.*; Clemens,R**; Hess,G.*.
*First Medical Department, University of Mainz, D-6500 Mainz, FRG, **Smith Kline Dauelsberg, D-8000 München, FRG.

Objective. HBsAg may activate T cells as indicated by gamma interferon production. The effect of vaccination against hepatitis B on the CD4+ cell count in anti-HIV positive individuals was investigated to elucidate whether there might be a detrimental effect on the progression of HIV disease.
Methods. 13 anti-HIV positive homosexual men aged 25-64 years (mean 39.8 years), being asymptomatic and belonging to stages II and III CDC II were vaccinated. The control group consisted of 17 matching homosexual, unvaccinated and HBsAg negative men also being anti-HIV postive, asymptomatic and belonging to stages II and III CDC II. Patients were vaccinated with three doses of recombinant hepatitis B vaccine (Smith Kline Dauelsberg) according to the standard 0, 1 and 6 month schedule. The individual vaccine dose was 20 ug HBsAg. CD4+ cells were analysed before the initial and one month after the final hepatitis B vaccination and at a 7-month interval in the control group, respectively. CD4+ cells were measured using a monoclonal antibody (Ortho Diagnostics) and a fluorescence-activated cell sorter (FACS).
Results. In vaccinated anti-HIV positive homosexuals, one month after the last vaccination a 22,4% decrease in CD4+ cell count was noted, compared to prevaccination results. Unvaccinated homosexual men showed an average decrease in CD4+ cells of 24.9% when analysed after the same period of time.
Conclusion. This study indicates that Hepatitis B vaccination in anti-HIV positive men has no detrimental effect on the CD4+ cell count. Apparently, a multitude of factors, but not hepatitis B vaccination is responsible for the progression of the HIV infection which ultimately leads to immunodeficiency and full-blown aquired immunodeficiency syndrom.

Th.B.P.116 PHENOTYPIC ANALYSIS OF LYMPHOCYTE SUBSETS IN A DIFFUSE INFILTRATIVE LYMPHOCYTOSIS SYNDROME (DILS) ASSOCIATED WITH HIV INFECTION.

Silvia Itescu, L. Brancato, J. Dalton, R. Perdue and R. Winchester, Hospital for Joint Diseases, NYU Medical Center, New York, NY, U.S.A.

Objective. To characterize a Sjögren's syndrome-like disorder in HIV-infected individuals with circulating and diffuse infiltrative CD8 lymphocytosis associated with HLA-DR5 (DILS) and to determine whether particular lymphocyte subsets are selectively expanded.
Methods. Patients were ascertained by referral for clinical evaluation to the Rheumatology Service at New York University. Analysis of peripheral blood lymphocyte populations was performed in patients with DILS, HIV-positive controls, and normal controls. Cells were stained with anti-CD4 and anti-CD8 antibodies, as well as directly conjugated anti-CDw29 and anti-CD45R antibodies.
Results. DILS is manifested clinically by generalized adenopathy, sicca symptoms, lymphocytic interstitial pneumonitis, and, less frequently, lymphocytic hepatitis and neurologic complications. Among 12 patients studied, only one instance of opportunistic infection has been found in up to 5 years of follow-up. Patients with DILS had significantly higher numbers of $CD4^+$ cells than HIV-positive controls, mean 368 vs. 142/mm^3 ($p<0.05$), a relative preservation of the $CD4^+CDw29^+$ subset when compared to normals, and a marked increase in the ratio of $CD4^+CDw29^+$ to $CD4^+CD45R^+$ cells. Paralleling the massive increase in $CD8^+$ cells, patients with DILS had significantly higher numbers of $CD4^-CDw29^+$ cells, 1089/mm^3 vs. 323 for HIV controls and 371 for healthy controls ($p<0.01$). The degree of glandular and pulmonary lymphocytic infiltration correlated with the absolute numbers of both the circulating $CD8^+$ and $CD4^-CDw29^+$ populations.
Conclusion. Taken together with the HLA-DR5 association in DILS, these data would suggest that MHC-restricted antigen presentation activates the $CD4^+CDw29^+$ helper-inducer lymphocyte subset leading to an expanded population of $CD4^-CDw29^+$ cells. As $CD4^+CDw29^+$ cells are required for the differentiation of cytotoxic CD8 cells, the $CD4^-CDw29^+$ subset, which presumably defines the circulating CD8 population in DILS, is currently the subject of detailed characterization.

Th.B.P.118 HIV-INFECTED SUBJECTS RESPOND TO POLIO VACCINATION BOOSTER ACCORDING TO ABSOLUTE T4 CELL COUNT.

Verdinon, Murit*; Handsher,R.**; Zackut,V.*; Burke,M.*; Hasner,A.* and Yust,I.*
*Clinical Immunology Unit, Tel Aviv Medical Center, Israel; **Central Virus Laboratory, Shiba Medical Center, Israel.

HIV infection is known to impair both cellular and humoral immunity. We studied the immunity to Polio virus in homosexual HIV-infected patients by measuring the level of antibodies against polio virus before and after i.m. booster vaccination with Salk Poliomyelitis vaccine (Connaught). 16 HIV seropositive homosexuals, average age 30 (25-50), were tested for neutralizing antibodies to poliovirus types I,II and III, using the 24 hour incubation method. In addition, the number of peripheral blood T4 cells and the lymphocyte stimulation following PHA, Con A and PWM were estimated. Prior to booster, all subjects demonstrated neutralizing antibodies to the three types of poliovirus. Following Salk vaccine booster, a rise in antipoliovirus antibody titer to one or more serotypes was noted in 12 subjects (see Table).

Group	No. seropositives	T4/ml	T4/T8	Response to Polio Vaccine		
				I	II	III
A.	5	600-1050	2.08±0.70	4/5	5/5	5/5
B.	6	200-400	0.49±0.08	6/6	5/6	5/6
C.	5	30-80	0.21±0.06	2/5	1/5	0/5

The response to Salk booster immunisation correlates with the number of circulating T4 cells and to the T4/T8 ratio. Further correlation was found with the mitogen-induced lymphocyte stimulation index.

Th.B.P.120 IMMUNOLOGIC ASPECTS OF MULTIPLE SIMULTANEOUS VACCINATION IN HIV SEROPOSITIVE SUBJECTS

Rhoads, Joanne*; Birx, D.*; Redfield, R.*; Burke, D.S.*,
*Walter Reed Retrovirus Research Group, Washington, D.C., U.S.A.

Objective: To identify immunologic factors predictive of response to immunization by HIV seropositive subjects, and to evaluate the effect of vaccination on the activation of T and B cells.
Methods: 21 asymptomatic HIV seropositive subjects who had received multiple vaccines were evaluated for vaccine response and immunologic function, including full blood count with cell phenotype analysis, serum immunoglobulins, DHS, T and B cell proliferation responses and immunoglobulin production. 20 normal subjects were similarly evaluated after vaccination, and also underwent cell phenotype analysis with double staining for CD3, CD4, or CD8 along with activation markers CD25, 4F2, DR, transferrin, VLA-1 on days 0,1,2,3,6,8,10,15, and 30. B cell analysis included CD20 with 4F2. Serum and supernatant assays for IL-2, IL-2R, α-INF, and immunoglobulins were performed.
Results: HIV seropositive vaccine non-responders had significantly higher spontaneous IgG production than HIV seropositive responders, as well as loss of suppression of EBV driven immunoglobulin production. There was no evidence of significant activation of the circulating T and B cell population after vaccination in any of the normal subjects.
Conclusion: There are subsets of asymptomatic HIV seropositive subjects capable of normal vaccine response; they can be distinguished by assays of B and T cell function. In addition, there is no evidence in normals of significant B and T cell activation after intensive immunization.

Th.B.P.121 CORRELATION BETWEEN HISTOLOGICAL CHANGES IN LYMPH NODES AND ALTERATIONS OF CELLULAR IMMUNITY IN DRUG ADDICTS AT RISK FOR AIDS.

Fernández-Cruz, Eduardo; Zabay, J.M.; Tardío, J.; González, B.; Escalona, J. and Menarguez, J.
Hospital General "Gregorio Marañón", Madrid, Spain.

Fifty HIV-positive I.V. drug addicts (IVDA) with palpable lymphadenopathy and 40 healthy individuals were selected for this study. Lymph node biopsies were fixed in formaline or B5-fixative and processed by histological methods. According to the classification of Biberfeld and based on our results and analysis of the statistical relationship between immunological values and histological parameters we have defined two main histologic stages. Stage I is characterized by: presence of follicles, ussually with prominent germinal centers, signs of follicular involution (lymphoid infiltrates, absence of follicular differentiation areas, etc),and paracortical nodules (tertiary nodules). Stage II is characterised by: absence of follicles or presence of follicular remnant scars, architectural generalized effacement with abnormal angiogenesis,and plasmocytosis. A comparison between histologic stage I and II in relation to T-cell subsets and cellular immune function evaluation in HIV-positive IVDA have shown significant differences between both groups. The differences were marked (p<0.001) in relation with number of CD4$^+$ cells, CD4/CD8 ratio, blastogenic response to PHA and percent of anergy. In the group of 50 IVDA we also found that histologic stage II was associated with the more severe clinical manifestations of HIV infection. 89% of patients with AIDS were distributed in histologic stage II. In contrast, 93% of patients in early stages of HIV infection (G.II, G.III and G.IV-E) were in histologic stage I.Lymph node histology is useful for the assessment of the severity of HIV infection.

Immunologie : protéines plasmatiques/Immunité humaine

Th.B.P.122 SERUM INTERFERON α IN ANTI HIV-1 POSITIVE PATIENTS IS DIFFERENT FROM IN VITRO PRODUCED INTERFERON α

Voth R., Rossol S., Laubenstein H.P., Böttner M., Müller W.E.G.*, Schröder H.C.*, Hess G. and Meyer zum Büschenfelde K.H.
I. Medizinische Klinik und Poliklinik der Johannes Gutenberg Universität Mainz und *Institut für Physiol. Chemie, Universität Mainz, FRG.

OBJECTIVE: Acid labile interferon α (IFNα) has been dedicated to patients positive for antibodies to human immunodefiency virus-1 (HIV-1) who developed AIDS-related complex (ARC) or acquired immunodeficiency syndrome (AIDS). It has been demonstrated in vitro that stimulation of peripheral blood mononuclear cells (PBMC) from healthy donors with HIV-infected cells causes production of acid labile IFNα whereas free infectious virus (HIV) itself leads to conventional IFNα in these cells.
METHODS: 164 HIV positive patients included in a study were tested for IFNα in the serum. For quantification of IFNα a highly specific ELISA was applied.
RESULTS: It turned out that all patients who had serum levels more than 5 - 8 IU/ml IFNα showed progression in the disease. 14 of these patients at stage CDC 3/WR 4 - 5 yielded average IFNα levels of (Mean ± SD) 24 IU/ml ± 19. IFNα levels up to 104 IU/ml were measured in 23 patients with full blown AIDS (stage CDC 4/WR 6, 40 IU/ml ± 27). Serum samples of these patients were treated with HCl at pH 2 for 24 h at 4°C. After retitration using NaOH to pH 7 we failed to detect any IFNα in these probes, indicating that the produced IFNα was acid labile. In contrast acid-stabile IFNα has produced in vitro by PBMC of these patients in turn to stimulation with IFN inducers (vesicular stomatitis virus, 5 x 10^5 PFU/ml). A significantly decrease of this VSV produced IFNα occured with the progress of the disease.
CONCLUSION: Functional properties of acid-labile IFNα in vivo are still ill defined and under present evaluation.

Th.B.P.123 SERUM IMMUNOGLOBULIN PROFILE IN HIV INFECTION

Tavares, Luis; Botas, J.; Feliciano, H.; Carvalho, C.; Antunes, F.; Paiva, J.D. et al.
Department of Infectious Diseases, Santa Maria Hospital, Lisbon, Portugal.

Objective. To study the correlation between immunoglobulin serum concentration (IgG, IgA and IgM) and the clinical evolution in HIV infection.
Methods. The serum concentration of immunoglobulins were measured by standard biochemical methods in 90 patients with HIV-1 or HIV-2 infection, treated from July.85 to January.89.
Results. An increase of immunoglobulin concentration was recognized in 76 out of the 90 patients (82%). The IgG values in the 36 asymptomatic carriers (AC): normal in 12 (33%) with a mean of 2159.4 mg/100ml, prallels that of IgG in the 38 AIDS patients: normal in 14 (36%), mean- 2115.3 mg/100ml. IgM profile was identical to that of IgG i.e., normal values in 13 AC and in 13 AIDS patients, with intermediate concentrations in patients with PGL and ARC as observed with IgG. The mean IgA serum concentration was within normal range in all stages of infection, but an uniform and significative increase was observed along with disease progression. there were no statistical differences between HIV-1 and HIV-2 infected patients. there were no striking differences among AIDS patients with opportunistic infections, namely tuberculosis and CNS-toxoplasmosis, and a group of patients with these two infections simultaneously.
Conclusions. Although the predictive value of high serum Ig concentration is very poor, a normal but increasing IgA could probably be of value if used in conjunction with other immunological, biochemical and clinical investigations of HIV infected people.

Th.B.P.124 EVALUATION DES ANTIGENES PHENOGLYCOLIPIDIQUE ET SULFOLIPIDIQUES DE MYCOBACTERIUM TUBERCULOSIS POUR LE DIAGNOSTIC SEROLOGIQUE DE TUBERCULOSE CHEZ LES MALADES ARC ET SIDA.

BERLIE H.C.*; CRUAUD Ph.**; PAPA F.**; DAVID H.**; DAGUET G.L.*
* Hôpital SAINT-ANTOINE, Paris, France.
** Unité de la Tuberculose et des Mycobactéries, Institut Pasteur, France.

Objectif : Mise au point d'un immunodiagnostic rapide de la tuberculose chez les malades ARC et SIDA.
Méthode : population = 4 groupes de patients sont étudiés : a) sujets sains b) tuberculeux HIV ⊖ ; c) sujets HIV ⊕ non tuberculeux; d) tuberculeux HIV ⊕
Immunodiagnostic : Elisa utilisant les antigènes PGL Tb1; sulfolipide I et sulfolipide IV de mycobactérium tuberculosis.
Résultats : taux de positivité (%) de l'immunodiagnostic (données provisoires)

Population	Ag PGL TB1	SL I	S IV
Sujets sains	0 %	0 %	0 %
Tuberculeux HIV ⊖	10 %	55 %	79 %
Sujets HIV ⊕ non tuberculeux	10,5 %	10,5 %	21 %
Tuberculeux HIV ⊕	30 %	10 %	40 %

Conclusion : Ces résultats préliminaires soulignent l'intérêt d'un test sérologique pour le diagnostic rapide de la tuberculose chez les malades ARC et SIDA.

Th.B.P.125 THE COMPOSITION OF CIRCULATING IMMUNE COMPLEXES (CIC) IN HIV-INFECTED INDIVIDUALS BY C1Q- AND C3D-BINDING ELISA.

Schwartzer, Thomas; Nahass, R. and Gocke D.
Robert Wood Johnson Medical School, New Brunswick, New Jersey, USA.

Objective. The presence of HIV-specific and nonspecific IgG circulating immune complexes (CIC) in HIV-infected persons has been reported, usually measured as C1q-binding complexes by labor-intensive techniques. We measured total C1q-IgG and C3b-IgG CIC in sera obtained from 38 HIV-infected persons.
Methods. A rapid (3h) C1q- and C3d-binding ELISA (Immunomedics, Warren, NJ) was employed. The concentration of CIC was expressed as ug/ml heat-aggregated human globulin (HAG) equivalents from a standard curve.
Results. Significant levels(>35 ug/ml) of C1q-IgG CIC were detected in 7/9 subjects in CDC group II (64±15 ug/ml), 3/5 subjects in CDC group III (39±13) and 14/24 subjects in CDC group IV (51±15 ug/ml). Similarly, C3d-IgG CIC (>9 ug/ml) were present in 7/9 CDC group II (28±10 ug/ml), 4/5 CDC group III (16±2 ug/ml) and 17/24 of those in CDC group IV (25±22 ug/ml). Thus, significant levels of CIC were detected in 32/38 (88%) infected subjects. CIC were not detected in HIV-seronegative controls. Of 32 CIC positive subjects p24 antigenemia was lacking in 5/7 subjects in CDC group II, 3/4 in group III and 15/21 in group IV. Collectively, p24 antigen was absent in 23/32 CIC positive infected subjects (p=<.002, Fischer's Exact Test).
Conclusion. We conclude that the C1q- and C3d-binding ELISA are useful for quantitation of CIC in HIV-infected individuals. The significance and utility of CIC measurements in p24 antigen negative infected subjects warrants further investigation.

Th.B.P.126 AUTOREACTIVITY IN PATIENTS INFECTED WITH HIV

Andrzejewski, C; Benton, J.; Valtier, S.; Lucey, D. and Boswell, Neal.
Wilford Hall USAF Medical Center, Lackland AFB, Texas, USA

Objective. To characterize and correlate the occurrence of autoantibodies (autoab) in HIV infected patients with their disease status as defined by the Walter Reed (WR) staging classification.
Methods. Sera from a total of 90 patients were examined using standard laboratory serologic techniques (indirect immunofluorescence) for the presence of autoab to nuclear antigens (ANA), cytoplasmic antigens (ACYA), smooth muscle (ASMA), mitochondria (AMA) and rheumatoid factors (RF). Both human and murine tissues served as substrate in the ANA testing.
Results. Autoreactivity was observed in patients from all WR stages. The percentage of patients positive for ASMA increased with the WR stage (WR1, 63%; WR2, 82%; WR3, 83%, WR4, 100%; WR5, 92%, WR6, 100%). No patients possessed AMA. RF activity varied in each group. Overall ANA positivity using human HEP-2 cells was 48%. WR stage 2 had the highest number of patients positive (82%), with all other WR stages having less than 45% positive. In marked contrast, overall ANA positivity on rodent tissues was less than 10%. Thus, the detection of ANA in HIV infected patients was highly dependent on the substrate used for testing.
Conclusion. These results demonstrate that the occurrence of autoab is a common finding in HIV infection. Further, autoab frequency and specificity vary in patients within different WR stages. The choice of substrate for autoab testing appears important in the detection of certain autoab (e.g. ANA) in HIV infected patients.

Th.B.P.127 COMPLEMENT ACTIVATION IN HIV INFECTION OCCURS THROUGH THE CLASSICAL PATHWAY AND REFLECTS DISEASE SEVERITY.

Peakman, Mark*; Senaldi, G.*; McManus, T.**; Davies, E.*; Gellan, M.**; Tee, D.*; Vergani D.*.
*Departments of Immunology and **Genito-Urinary Medicine, King's College School of Medicine and Dentistry, London, U.K.

Objective. Using a direct and pathway specific approach, to assess whether complement (C) activation occurs in HIV infection and its relationship to circulating immune complexes (CIC) and disease severity.
Methods. We studied 15 healthy controls and 65 subjects attending an outpatient STD clinic comprising 21 HIV negative controls and 44 HIV positive patients (7 asymptomatic/PGL, 22 ARC, 15 AIDS). C4d, Ba and C3d, fragments specific to the classical, alternative and common pathways, were measured by nephelometry after isolation with polyethylene glycol. Intact components C4, Factor B and C3 and CIC were quantified by nephelometry and the fragment to parent molecule ratios (i.e. C4d/C4) calculated to give an index of activation independent of the initial concentration of the intact components.
Results. There was marked activation of C proceeding through the classical pathway in all HIV positive groups as shown by significant elevations of C4d, C4d/C4, C3d, C3d/C3 ($p < 0.001$ for all) compared with controls and this was accompanied by a comparable increase in CIC ($p < 0.001$). Moreover, the increase in these parameters was linear through the subject groups from healthy controls to AIDS. There was no C activation through the alternative pathway in any of the patient groups.
Conclusion. Activation of C in HIV infection proceeds through the classical pathway, consistent with triggering by CIC, and reflects disease severity.

Th.B.P.128 SERUM IgD LEVELS IN THE COURSE OF HIV INFECTION.

Vivinus,M.*; Quaranta,J.F.*; Cassanovas,C.*; De Matteis,M.*; Cassuto,Jill-Patrice**; Dellamonica,P.***.
* Laboratoire d'Immunologie, ** Médecine Interne, *** Maladies Infectieuses, C.H.R.U. Nice, France.

Objective. Polyclonal hyperIgG, IgA or IgM is a common abnormality observed in HIV patients and explained by B cells activation. IgD levels have been much less thoroughly studied. In a cohort of 87 HIV+ patients (HIV+) and 82 HIV- controls (HIV-) we have assayed IgD and attempted to correlate levels with CDC groups, T4 cells, IgG, IgA and IgM, HBV antigenemia.
Methods. T4 cells : cytofluorometry, Ig : nephelometry, HBs antigen : ELISA.
Results. IgD levels did not correlate with IgG, IgA, IgM levels nor with T4 cells number. Since a difference between means is observed (HIV+ $\bar{m}$ = 288.5, sd = 286.5; controls $\bar{m}$ = 130.2, sd = 159.1), noteworthly the incidence of high levels (>400 mg/l) dramatically increased in HIV+ (20/87) compared to HIV- (2/82), more particularly in II and IVc2 groups. In 12/16 AIDS cases, IgD levels were low. The most noteworthly is the levels dispersion in a wider range in HIV+, particularly not yet AIDS, with high levels absent in controls. Furthermore, HBV infection affected IgD values more in HIV+ (HBs+ $\bar{m}$ = 398.7, sd = 279.3; HBs- $\bar{m}$ = 255.6, sd = 283.6) than in controls (HBs+ $\bar{m}$ = 190.6, sd = 80.8; HBs- $\bar{m}$ = 130.2, sd = 159.1). All HIV+ presented stigmata of former EBV infection, so it has not been held as a discriminating criterion.
Conclusion. It's remarkable that HIV infection influences serum IgD levels, this fact having been reported in few diseases. HyperIgD may reflect an unusual type of B-cell activation in HIV infection and perhaps may be used as an early marker of it.

Th.B.P.129 MONOCLONAL GAMMOPATHIES IN HIV INFECTION.

Vivinus,M.*; Quaranta,J.F.*; Cassanovas,C.*; Ferrari,P.*; Dellamonica,P.**; Cassuto,Jill-Patrice***.
* Laboratoire d'Immunologie, ** Maladies Infectieuses, *** Médecine Interne, C.H.R.U. Nice, France.

Objective. Monoclonal gammopathies (MG) recently have been reported in HIV infection. We purpose to evaluate the incidence of MG in a cohort of 210 HIV patients and their clinical and biological characteristics.
Methods. Sera samples were tested by serum proteins electrophoresis, immunofixation, immunoelectrophoresis and nephelometry for Ig assay.
Results. 17 MG (isotypes : 9 IgG, 2 IgA, 5 IgM, 1 IgM/G biclonal) and 2 abnormal light chains (LC) have been observed. The kappa LC prevail (lambda LC 5 times). These 19 patients, followed up from 2 to 12 months, were all T4 lymphopenic, 16 AIDS and 3 asymptomatic. In 4, bone marrow study showed a non specific polyclonal lymphoplasmocytosis. Actually, we observed no development of B-cell lymphoma in all patients tested. Furthermore, monoclonal peaks persist contrary to transitory ones reported in others viral infections e.g. A or B viral hepatitis. Besides T4 lymphopenia, other immune abnormalities (various autoantibodies, immune complexes) often are encountered suggesting that induction of MG may be related to polyclonal activation of B cells and aberrent B-cell immunoregulation after HIV infection.
Conclusion. In our series, the incidence of MG in HIV patients, principally AIDS, was low (9.0%) but yet surprising in such a young population. However, the occurence of B-cell clones in immunosuppressed, "dysimmune" and overstimulated patients is logical.

Th.B.P.130 ADENOSINE DEAMINASE (ADA) LEVELS IN TEARS OF AIDS PATIENTS AND AIDS CARRIERS

Eto, Kotaro: Tsuboi, I.: Saneyoshi, Y.: Yoshioka, M. and Yokoyama, M.M.
Kurume University School of Medicine, Kurume, Japan.

Objective. To determine the activities of purine nucleotide metabolic enzymes in body fluids provide information on retrovirus infection in particular,lin relation with ophthalmologic and neurological disturbances.
Method. Approximatory 30ul tear was collected by cappillary action with use of 10ul glass micropipette. ADA activity was measured based on the conversion of adenosine to hypoxanthine.
Results. The ADA enzyme levels were significantly elevated in AIDS patients as compared with AIDS carriers. The ADA levels were not elevated in AIDS carriers and the levels were found to be similar to normal controls. The AIDS patients with markedly elevated ADA level tend to correlate with an appearance of ophthalmological and neurological disturbances.
Conclusion. The measurement of adenosine deaminase activity in tear provides useful clinical information for monitoring the course of AIDS.

Th.B.P.131 BULLOUS PEMPHIGOID (BP) TYPE ANTIBODIES IN HIV-INFECTED PATIENTS.

KINLOCH-de LOES Sabine, DIDIERJEAN L. and SAURAT J.-H.
Clinique de Dermatologie, Hôpital cantonal universitaire. CH 1211 Genève 4. SUISSE.

-Objective: to determine if HIV- seropositive patients with pruritus have antibodies against skin antigens.
-Methods: direct immunofluorescence (DIF) test on involved and uninvolved skin, indirect immunofluorescence (IIF) test on normal human skin as substrate and western blot analysis of normal human epidermal extracts.Ten HIV-seropositive patients (9m.,1f.) with pruritus,
8 without pruritus; as controls, a panel of HIV- seronegative patients with inflammatory dermatoses and with the pruritic autoimmune skin disease bullous pemphigoid (BP) were studied similarly.
-Results: an unexpectedly high proportion of HIV-seropositive patients (12/18: 66%) was found by western blot to have circulating antibodies to epidermal antigens in the range of 240-220 and 180-160kD, which is the MW of BP antigen. This compared to 81% of positivity in HIV- seronegative patients with BP and to 0% of patients with other inflammatory dermatoses. One HIV- seropositive patient had a positive BP-like IIF and another one a positive BP-like DIF. Follow-up studies indicated that in HIV- seropositive patients, positive BP-like western blot was not correlated with the presence of pruritus, was detectable early in the course of infection (i.e. shortly following HIV seroconversion). In several cases the BP-like antibodies were no longer detectable during AZT therapy.

-Conclusion: HIV-seropositive patients frequently develop antibodies against human skin antigens of MW identical to the autoantigens of BP. The significance of this phenomenom is under study; so far a cross-reaction with HIV antigens is partially excluded because sera of BP patients do not react with HIV1 antigens on western blot analysis.

Th.B.P.132 COMPARISON OF THE IMMUNOGLOBULINS (IG) PROFILE BETWEEN WHITE PATIENTS (PTS) INFECTED IN AFRICA (WA), WHITE PTS INFECTED IN EUROPE (WW) AND BLACK PTS INFECTED IN AFRICA (AA)

Vandercam B., Senagui D., Cahill M., Omar M., Fernez P., Sech F.
St-Luc University Hospital, 1200 Brussels, Belgium.

Aim of the study :
Differences in IG profile between AA group and WW group may be due to variations of infecting HIV or to the host immune response.
Accordingly we have compared white pts HIV-infected in Africa with White pts HIV-infected in Europa.
Population : WW pts : 15, 5 respectively at stage II-III and IVA-IVC$_2$.
AA pts : 18, 9, 5 respectively at stage II-III, IVA-IVC$_2$ and IVC$_1$.
WA pts : 16, 6, 7 respectively at stage II-III, IVA-IVC$_2$ and IVC$_1$.
Results : are summarized as follows : (% of the normal value)

STAGE	IGA(%)			IGM(%)			IGG(%)		
	AA	WA	WW	AA	WA	WW	AA	WA	WW
II - III	115	148	120	170	190	188	281	153	151
IVA-IVC$_2$	142	160	228	209	214	399	287	179	204
IVC$_1$	224	132	-	170	200	-	230	167	-

At stage II-III and IVA-IVC$_2$, IGG levels were significantly higher in AA group than in WA or WW group. At stage IVC$_1$, IGA and IGG levels were significantly higher in AA group.
In conclusion, we found no difference at stage II-III, IVA-IVC$_2$ in IG profiles between White pts infected in Africa and White pts infected in Europa. Accordingly, in our opinion the difference in IG profiles between African pts and White pts infected in Africa or in Europa is probably related to racial factors rather than HIV-variation.

Th.B.P.133 Antibodies to endogeneous interferonα in controls and HIV infected persons in different disease states.

Joller-Jemelka Helen I. * and Joller Peter W. **
* University Hospital Zurich, Zurich, Switzerland, ** ANAWA Laboratories, Wangen, Switzerland

In serum samples of 180 HIV positive persons (CDC II n=45; CDC IV n=64; CDC IV C,D n=71) 10 quantitative markers were analysed: HIV antigen, antibodies to HIV core, antibodies to HIV envelope, beta-2-microglobulin, serum neopterin, interferon alpha, antibodies to interferon alpha, serum IL-2 receptors, tumor necrosis factor alpha and serum IL-1. The results were compared to the values of 60 healthy blood donors. There is a statistically significant difference between blood donors and every single HIV infection group. But within HIV positives, in all 3 groups certain patients showed extremly high values in the different parameters. These pronounced fluctuations make it impossible to statistically separate the clinically defined disease groups in all but one serum parameter. The exception is: antibodies to endogenous interferon alpha (anti IFNα) . In parametric and nonparametric statistical analysis the titer of antibodies to IFNα significantly differ between the CDC groups. Anti IFNα titers were determined in a highly sensitive, commercially available EIA test kit and confirmed by the neutralization test (1).

Anti IFNα do not correlate with the interferonα level in the individual person. Neither in one of the different groups nor in the whole sample. The biological significance of antibodies to endogenous IFNα is not yet clear. Already Gresser (2) gave a possible explanation why autoantibodies to IFNα are produced. Whether these anti IFNα are enhancing (3) or reducing (4) the IFNα action is a matter of controversy. This issue has to be clarified in the near future. Our results are especially interresting in the light of the proposal of anti IFNα as a therapeutic approach (5).

Th.B.P.134 COMPLEMENT LEVELS AND CIRCULATING IMMUNE COMPLEXES IN A CONTROLLED, LONGITUDINAL, MULTICENTER STUDY ON EFFECTS OF INTRAVENOUS IMMUNOGLOBULIN (IVIG) IN ADULTS WITH ARC/WRS

Peter J. Späth[1], G. Mauff[2] and the ARC-IVIG-Study-Group Cologne/Berne ([1]Central Laboratory, Blood Transfusion Service SRC, Berne, Switzerland, and Depts. of Internal Medicine II, Pathology, Dermatology, Virology, [2]Med. Microbiology, and Biostatistics, Univ. of Cologne, FRG)

Objective. The complement system, the effector mechanism of the antigen-antibody reaction and the main mediator of inflammation, and the formation of circulating immune complexes were examined to study safety of intravenous immunoglobulin (Sandoglobulin) in adults with ARC/WRS which took part in a randomized, placebo-controlled double blind trial.
Methods. Blood sampling was done on days 1, 85 and 183 of the study. Complement was assessed by radial immunodiffusion, nephelometry, cellular intermediates and monoclonal antibodies to neoantigens of activated complement proteins. Circulating immune complexes were measured as the C1q-binding activity of the serum or the amount of C3-breakdown products bearing IgG captured by solid-phase monoclonal anti-human C3dg.
Results. 13 patients receiving IVIG (0.4 g/kg b.w. every two weeks for 6 months) and 12 patients receiving the same volume of a placebo solution (0.03% human albumin) were analyzed. On day 1 of the study 3/13 (IVIG) and 4/12 patients (placebo) had C4 levels below the normal range. Total complement hemolytic activity (CH50) was below the normal range in 6/13 and 3/12 patients, respectively. C9, a sensitive acute-phase complement protein, was above the normal range in 10/13 and 8/12 patients. Elevated C1q-binding activity (C1q-BA) was found in 7/13 and 9/12 patients, respectively. In contrast, elevated level of C3dg-bearing IgG was observed in only 1/13 and 2/12 patients. In both groups of patients an inverse correlation between CH50 value and C1q-BA (r > -0.867) and CH50 and level of *in vivo* C4 activation (r > -0.765) emerged. At no time did one of the parameters show a significant difference between the two groups of patients. None of the mean levels of parameters tested changed significantly during the observation period.
Conclusion. The infusion of IVIG to immune complex positive or negative adults with ARC/WRS does not induce formation of circulating immune complexes. The complement system in such patients is not disturbed by the IVIG infused. Based on these results infusion of IVIG to patients with ARC/WRS is safe, a fact also observed by clinical parameters (cf: *Schrappe-Bächler et al.*).

Th.B.P.135 SERUM IGE LEVELS VARY WITH ABSOLUTE CD4A LYMPHOCYTE COUNTS IN HIV-POSITIVE PERSONS

Lucey, Daniel; Zajac,R.; Melcher,G.; Butzin,C. and Boswell, R.N.
Wilford Hall Medical Center, US Air Force HIV Program, Lackland AFB
San Antonio, Texas, USA.

Objective. To determine whether serum IgE levels change with absolute CD4a lymphocyte counts.
Methods. 740 HIV-positive persons had at least one IgE level, including 71 with CD4a counts of 0-200. Serum IgE levels were measured by RIA (Normal range 0-180 IU/ml). An analysis of variance was performed comparing serum IgE levels with CD4a counts.
Results.

CD4a Count	Mean IgE	#Samples	Std.Error	Min.IgE	Max.IgE
0-200	567	80	140	3	6265
200-400	196	144	42	4	3736
400-600	127	280	24	2	5600
600-800	148	290	25	3	4910
800+	105	307	14	2	2389

Conclusion. Serum IgE levels in a large cohort of HIV+ persons are linearly related (F-Ratio 30.3, p less than .01) to the absolute CD4a count, being highest in persons with 0-200 CD4a lymphocytes. This finding may be relevant to the frequent drug reactions seen in HIV-positive persons and to the release of IgE binding factors by T cells of HIV-positive persons. (Proc. Natl. Acad. Sci. 1988;85:9214-9218).

Th.B.P.136 PLASMA FIBRONECTIN (PFN) LEVELS IN PATIENTS WITH HIV INFECTION.

Torre,Donato*;Sampietro,C.*;Issi,M.**;Ferraro,G.*;Mascialla, A.*. *Division of Infectious Diseases and **Blood and Immunotrenfusional Center, Regional Hospital, 21100 Varese, Italy.

Objective. Several biological markers have been studied in patients with HIV infection to evaluate their diagnostic value. Fibronectin plays an important role in opsonic functions and it can bind to bacteria,viruses,some protozoan parasites and Candida species. Fibronectin may be an important component in immune complexes during viral infections. Since fibronectin is capable of interacting either directly with viruses or with mononuclear cells, we determined the levels of PFN in patients with HIV infection.
Methods. Plasma samples were obtained from adult patients with HIV infection. Quantitation of PFN levels was performed by a radial immunodiffusion assay.
Results. In our study,we observed a significant diminuition of PFN levels in patients with HIV infection.This reduction was marked in ARC and AIDS patients.Moreover,AIDS-patients with P.carinii pneumoniae had low and persistent levels of PFN.
Conclusion. The low PFN levels observed in AIDS-patients show that PFN may act as a non specific opsonin involved in the clearance of viral particles. It is worthy to note that a specific tetrapeptide of the cell-binding site of fibronectin possesses a strict homology with a putative polypeptide chain encoded by HIV.

Th.B.P.137 SERUM AND SALIVARY IMMUNOGLOBULINS TO CANDIDA IN HIV POSITIVE INDIVIDUALS

Wray, David and Felix, D.H.
University of Edinburgh, Edinburgh, U.K.

Objective. To determine the prevalence of candidal carriage and infection in a group of HIV positive individuals and to compare the humoral immune responses in serum and saliva in this group with a control group of HIV negative subjects.
Methods. Patients were examined clinically with particular reference to the presence of candidal lesions and oral swabs taken to identify carriers. Venous blood and whole saliva were obtained for estimation of total and anti-Candida antibody levels measured by radial immunodiffusion and ELISA assay respectively. 47 HIV positive individuals and 176 HIV negative controls were included in the study.
Results. Pseudomembranous candidiasis was the commonest clinical variant in HIV positive individuals and there was a 25 fold increase in the incidence of median rhomboid glossitis in this group compared to a normal population. Candida albicans was the commonest species isolated in both groups. Increased levels of anti-Candida IgG were found in both serum and saliva of HIV negative individuals who were either carriers or infected. This was associated with a reciprocal fall in anti-Candida IgA. Similar trends were seen in HIV positive individuals in association with candidal carriage and infection although the changes were more marked.
Conclusion These data demonstrate maintenance of systemic humoral immunity but reduced secretory immunity in HIV infection to Candida albicans.

Th.B.P.138 SERUM PROLACTIN LEVELS IN PATIENTS WITH HUMAN IMMUNODEFICIENCY (HIV) INFECTION

Nelson, Robert*; Wright, D.**; Russell, D.**; Ledford, D.**; Lockey, R.** and Good, R.*.
*All Children's Hospital, St. Petersburg, Florida, **University of South Florida College of Medicine, Tampa, Florida , USA

Objective. To measure serum levels of prolactin (PRL), a regulator of immunologic responses and cellular proliferation, in HIV-infected subjects.
Methods. Serum PRL was measured in 48 HIV-infected males (mean age 34 yr.), 13 HIV-negative male homosexuals (mean age 36 yr.), and 14 male heterosexuals by an immunoradiometric assay with a magnetic solid phase (MAIAclone, Serono Diagnostics). Geometric mean levels were compared between groups by the Wilcoxon two-sample test.
Results.

Group	n	PRL (ng/mL)	p value vs. 1) and 2)
1) Normal heterosexuals	14	3.6 + 0.4	———
2) HIV-negative homosexuals	13	3.1 + 0.7	———
3) HIV-infected	48	7.1 + 1.2	< 0.001
with Kaposis sarcoma	8	15.0 + 5.5	< 0.001*
without Kaposis sarcoma	40	6.1 + 0.8	< 0.02

*Significantly different from group without Kaposis sarcoma p < 0.02
There was no correlation between PRL levels and absolute numbers of CD4 or CD8 lymphocytes or CD4/CD8 ratios in the HIV-infected subjects.
Conclusion. Mean PRL levels are higher in HIV-infected subjects compared to HIV-negative homosexuals and normal heterosexuals. Levels are highest in those with Kaposis sarcoma.

Th.B.P.139 ACTIVATION OF THE ALTERNATIVE COMPLEMENT PATHWAY (AP) IN DIFFERENT STAGES OF HIV INFECTION

Ujhelyi, Eszter*, Hidvégi, T.*, Kirschfink, M.**, Füst, G.*, Bánhegyi, D.***, Zimonyi, I.**** et al.
*Natl.Inst.Haematol.Blood Transf., Budapest, Hungary, **Ruprecht-Karls-Univ., Heidelberg, FRG, ***Munic. László Hosp., ****Heim Pál Hosp., Budapest,Hungary

Objectives. Since some recently published data indicate that HIV-infected cells activate the AP, it seemed interesting to measure if C3bBbP complexes are present in the blood of HIV-infected patients. Formation of these complexes is a most sensitive marker of AP activation. Methods. C3bBbP complexes were measured by an ELISA method, plates were coated with properdin (P) antibodies, biotin-anti-C3b and avidin-peroxidase were used for the detection of complexes. Results. Freshly frozen (-70°C) EDTA plasma and serum samples were tested from healthy controls and from patients in different stages of HIV-infection:

Group	C3bBbP complexes in plasma No	plasma U/ml	serum No	serum U/ml
controls	18	41±15	18	240±39
asympt HIV+ haemophiliacs	21	58±46*	21	350±117***
ARC, AIDS	n.t.		17	248±56

* p<0.10
*** p<0.001

Conclusion. Our findings indicate that AP is activated in the asymptomatic stage of HIV-infection, whereas traces of this activation could not be detected in ARC and AIDS patients.

Th.B.P.140 GRANULOCYTE-ASSOCIATED IMMUNOGLOBULINS IN ASYMPTOMATIC HIV-INFECTED SUBJECTS

Lefrère Jean-Jacques*; Cartron, J.**; Celton, J.L.**; Rouger, P.*.
* Institut National de Transfusion Sanguine, Paris, ** Centre de Transfusion Sanguine, Necker, France.

Objective. To determine the prevalence of granulocyte-associated immunoglobulins (GA-IgG) during the follow-up of symptomless human immunodeficiency virus (HIV)-infected subjects.
Methods. 32 asymptomatic (stage II or III CDC) HIV seropositive subjects were studied. None received treatment before and during the study period. Quantification of GA-IgG by a granulocyte immunofluorescence test (GIFT) used Fab'2 fragments against total immunoglobulins or immunoglobulins G. Fifteen out of the 32 subjects had a second GIFT 3 months later ; 6 out of these 15 had a third GIFT 3 months after that.
Results. At the first control, 7 (21.8 %) out of the 32 subjects had a positive GIFT.

GIFT at 1st control	GIFT at 2nd control	N° of cases
-	-	3
-	+	6
+	-	0
+	+	6 *

(* GIFT was positive in these 6 subjects at the third control)
At the first control, mean CD4 in subjects with positive GIFT and without were respectively 414 and 350 (N.S. difference) ; mean neutrophil count in these two groups were respectively 3187 and 3349 (N.S. difference). No neutropenia was found.
Conclusion. GA-IgG are not responsible for neutropenia in symptomless seropositive subjects. Their frequency is high in this context and increases with time.

Th.B.P.141 Anticardiolipin Antibody (ACA) in patients with Human Immunodeficiency Virus (HIV) infection,

Ramon A. Arroyo M.D., R. Brey, J. Higgs, R. Boswell, Wilford Hall USAF Medical Center, San Antonio, Texas, N. Harris, University of Louisville, Kentucky, U.S.A.

The lupus anticoagulant (LA) and ACA are antibodies directed against phospholipid. A syndrome of thrombosis, spontaneous abortions and thrombocytopenia has been associated with these antibodies. ACA, LA and other antibodies have been found in sera of HIV infected patients. The role of these immunological abnormalities in HIV infection remains to be determined.
In this study ACA was measured on 265 HIV patients by Enzyme Linked Immunoabsorbent Assay. Screening for LA was done using a variety of clotting studies PT, PTT, Kaolin clotting time and Russel Viper Venom time. Patients were categorized according to Walter Reed stage. Results were as follows:

WR Stage	1-2	3-5	6	Totals
# of pts.	226	32	7(23%)	265
(+) ACA	85(37%)	13(40%)	2	100
(+) LA	6	1	0	7

Only one patient had a single episode of venous thrombosis. In addition, sera from ten (+) ACA patients were compared with sera of four antiphospholipid antibody syndrome (APL) patients, looking for cross-reactivity with a variety of phospholipid antigens. Both HIV ACA and APL ACA cross-react with negatively charged phospholipid. We conclude that even though ACA in HIV infected patients behaves in a similar way to ACA of APL pts., the presence of ACA in HIV infected patients does not seem to be associated with stage of disease or APL antibody related conditions.

Th.B.P.142 CD4+ LYMPHOCYTE AUTOANTIBODIES AS INDICATORS OF DISEASE PROGRESSION IN HIV INFECTION

Volker Daniel*, Rolf Weimer*, Klaus Schimpf+, and Gerhard Opelz*

*Department of Transplantation Immunology, Institute of Immunology, University of Heidelberg, and + Rehabilitation Hospital and Hemophilia Center, Heidelberg, FR Germany

The presence of IgG, IgM, C3d, or gp120 on the surface of T lymphocytes was analyzed by flow cytometry in blood samples from 73 hemophilia patients and 56 healthy controls. 12 patients had AIDS, 3 had AIDS-related complex (ARC), 1 patient had lymphadenopathy syndrome (LAS), 31 were HIV+ without AIDS, ARC or LAS, and 26 were HIV-. IgG and IgM autoantibodies against CD4+ lymphocytes were found in HIV+ hemophilia patients but not in HIV- patients or healthy controls ($p < 0.001$). IgM autoantibodies were more frequent than IgG autoantibodies. Autoantibody formation increased with disease progression ($p < 0.005$). However, within the same disease risk category, patients with autoantibodies were not "more immunologically abnormal" than patients without autoantibodies. HIV+ patients who possessed autoantibodies had similar CD4+ and CD8+ lymphocyte counts as HIV+ patients without autoantibodies. There was no significant difference in the number of patients with abnormal CD4/CD8 ratios, serum neopterin levels, or in-vitro responses to allogeneic stimulator cells or mitogens between autoantibody positive or negative patients of the same risk category. Our data suggest that autoantibodies against CD4+ lymphocytes may be helpful as indicators of disease progression, however, their immunopathogenetic role remains unclear.

Th.B.P.143 PREDICTIVE VALUE OF IgE IN HIV DISEASE.

Lahrousse, Françoise ; Israel-Biet, D. ; Tourani, J.M. ; Sors, H. ; Andrieu J.M. ; Even, P. HIV Study Group and Lab Biochimie Ehindjian BG. Hopital Laennec. 42 rue de Sèvres. 75007 - PARIS - FRANCE.

In a previous study, we reported that IgE increased significantly along the evolution of HIV infection. In an attempt to assess their predictive value, we compared 2 groups of HIV+ untreated non-atopic patients (pts) defined by their IgE values (group I: <150 UI/ml, group II: > 150, normal laboratory value <150). Both groups were similar with respect to age, sex, risk factors and to well-known predictive markers of AIDS i.e. CD4 cell counts and p24 antigenemia. Characteristics of the 2 groups are given in the table.

	n	CD4/ul (m+SEM)	p24 +	Asympt.	PGL	ARC
Group I	154	610+21	29(19%)	59(38%)	82(53%)	13(8%)
Group II	62	595+44	12(19%)	25(40%)	28(46%)	9(14%)

During the follow-up, AIDS occurred in 13 group I and 11 group II patients. The 30-month actuarial rate of AIDS occurrence are 21% and 41% in group I and II respectively (p=0.015). In conclusion: high levels of IgE in HIV patients, reflecting the early and severe dysfunction of T cells which normally tightly control IgE secretion, appear to be of poor prognosis in HIV infection.

Immunologie : molécules CD4 et autres marqueurs
Immunology: CD4 and Other Markers

Th.B.P.144 THE RELATIONSHIP OF CD-8 LYMPHOCYTE COUNTS TO AIDS PROGRESSION IN HIV SEROPOSITIVE MEN

Anderson, Robert E.*; Lang, W.**; Shiboski, S.***; Jewell, N.***; Busch, M.****; Winkelstein, W.***.
*ViRx, Inc., San Francisco, CA, USA; **Children's Hospital, San Francisco, CA, USA; ***University of California, Berkeley, CA, USA; ****Irwin Memorial Blood Bank, San Francisco, CA, USA.

Objective. To determine if CD-8 lymphocyte counts change the probability of subsequently developing AIDS in prevalent HIV seropositive men.
Methods. CD-4 and CD-8 lymphocyte counts (cells/ul) were determined on a probability sample from the San Francisco Men's Health Study, on whom AIDS incidence in the subsequent 30 months was ascertained.
Results. Fraction (%) of HIV+ men with AIDS at 30 months

	CD-4	<438	439-686	>687
	<831	17/46 (37.0)	2/31 (6.5)	0/20 (0.0)
CD-8	832-1203	5/30 (16.7)	3/29 (10.3)	0/38 (0.0)
	>1203	10/22 (45.5)	6/36 (16.7)	2/38 (5.7)

CD-8 is not a statistically significant predictor of development of AIDS if constrained to be linear in a Cox proportional hazards model with CD-4 and time to AIDS development. However, CD-8 becomes highly significant if allowed to be non-linear. The contribution of CD-8 to the relative hazard is high around 500 to 600, declines between 600-1000, and then is increasing and linear above 1000.
Conclusion. CD-8 lymphocyte counts modify the risk of developing AIDS. These findings suggest that in contrast to in vitro data, high CD-8 levels may increase the risk of subsequent AIDS development.

Th.B.P.145 A FOLLOW-UP OF IMMUNE PARAMETERS IN HIV INFECTED PATIENTS TREATED WITH LOW DOSE AZIDOTHYMIDINE (AZT).

Huygen K°., Pairon Y°° and Henrivaux P°°
°: Institut Pasteur van Brabant, 1180 Brussels
°°: CHU Sart Tilman, State University of Liège, Belgium.

Objective. To assess the effect of AZT on immune function of HIV infected patients.

Methods. Seven HIV infected patients were submitted to oral low dose AZT (9.0 ± 0.5 mg/kg/day). Immune function was examined at three-monthly intervals by in vitro lymphoproliferation towards PHA and PWM and for interferon α and γ production. Immune parameters at the onset of the study and the duration of AZT treatment were as follows:

Patients	CDC	Risk	T4/ml	T4/T8	PHA (cpm)	PWM(cpm)	AZT(weeks)
98	2	Africa	650	0.47	16952	2010	14
57	3	iv drugs	596	0.46	23456	5680	40
52	4C2	homo	359	0.82	31134	8685	36
97	4C2	Africa	144	0.15	15146	1877	18
128	4C2	homo	71	0.15	149	77	11
108	4C2	homo	292	0.34	14875	644	37
123	4D	homo	24	0.06	582	167	17

Results. All but one patient (patient N°123) presented an increase of CD4 cells during AZT therapy. However, no significant improvement of the immune function was observed during AZT treatment in any of the patients except in patient 57. Interpretation of this improvement must be made with precaution, as this patient concomitantly with the AZT treatment stopped his drug-abuse.

Conclusions. These preliminary results concerning patients with yet advanced disease suggest that low dose AZT induced an increase of OKT4 cells but couldn't improve the immune function.

Th.B.P.146 AN UPDATE ON THE LYMPHOCYTE IMMUNOPHENOTYPING QUALITY ASSURANCE PROGRAM IN SUPPORT OF THE ARMY HIV STUDIES.

Rickman, William J.*; Waxdal, M.J.**; Monical, C.**; Damato, J.D.*, and Burke, D.S.* *Walter Reed Army Institute of Research, Washington, DC, USA and **FAST Systems, Inc., Rockville, MD, USA.

Objective. To determine the degree of interlaboratory variability among Army Regional Medical Centers (AMC) that evaluate HIV patients.

Methods. Monthly shipments of 3 whole blood specimens are delivered by overnight commercial carrier to seven AMC for leukocyte and lymphocyte evaluations. CD2, CD3, CD4, CD8, CD19/20 and NK cells, were determined by a standard flow cytometric lymphocyte immunophenotyping protocol.

Results. Since June 1987, 382 specimens from 54 normal donors have been analyzed by the participating AMC with an overall standard deviation (SD) of 3.3 and coefficient of variation (CV) of 13.1% for all lymphocyte markers. The SD for CD4 percentages have ranged from 1.0 to 9.7% (mean of 3.3), while the SD for CD4 absolute counts have ranged from 69 to 477 cells/mm³ (mean of 227). The cumulative interlaboratory CV for the absolute CD4 count is 19.2%

Conclusion. In order to provide reliable CD4 determinations for multicenter HIV treatment protocols, a high degree of interlaboratory precision is required and can be achieved through the implementation a comprehensive quality assurance program.

Th.B.P.147 SOUS-POPULATIONS DE LYMPHOCYTES T CD4+CD45R+(2H4+) ET CD4+CDW29+(4B4+), CHEZ 70 PATIENTS AVEC INFECTION VIH.

BARBIER F.*, TOURAINE F.*, CAUDIE CHRISTIANE*, LIVROZET JM.**, QUINCY Cl.*, TOURAINE JL**.
* Lab. Immuno. Hop. Neurologique;** Pav. P. Lyon Hôp. E. Herriot, LYON FRANCE.

Objectif: Evaluer l'intérêt de la numération des lymphocytes CD4+2H4+ et CD4+4B4+ dans la prédiction de l'évolution chez les patients avec infection VIH.

Matériel et méthodes: °70 patients VIH+ répartis en 4 groupes. °Cytométrie en flux sur EPICS C® et double marquage (FITC-PHE) CD4.2H4 et CD4.4B4 (Anticorps monoclonaux Coulter Diagnostics).

Résultats:

Groupes.	Nbre de sujets	CD4+/mm³		CD4+2H4+/mm³		CD4+4B4+/mm³		Stade clinique (selon le CDC)
		m	SD	m	SD	m	SD	
Témoin	20	773	140	214	83	341	82	Sujets sains
1	16	732	149	186	83	181	79	II (Asymptomatiques).
2	14	462	38	122	62	184	71	II et III
3	24	297	75	63	33	136	69	III
4	16	237	94	59	42	123	60	IVc2

Il existe une diminution significative du nombre de cellules CD4+4B4+ dans le groupe 1 (asymptomatique) par rapport aux sujets témoins (P<0,0001, test t de Student) alors que ceux des CD4+ et des CD4+2H4+ ne sont pas significativement abaissés (P=0,44 et P=0,31).

La diminution des lymphocytes CD4+ dans le groupe 3 par rapport au groupe 2 est principalement due à l'atteinte des CD4+2H4+ (P<0,0001) sans différence significative pour les CD4+4B4+ (P=0,08).

Conclusions: Ces résultats préliminaires suggèrent que la sous-population CD4+4B4+ est altérée précocément dans l'infection VIH et pas la sous-population CD4+2H4+ qui décroît surtout à partir du groupe 2, donc à un stade évolutif plus avancé.

Th.B.P.148 CD4 AND TOTAL LYMPHOCYTE COUNT (TLC) IN PATIENTS WITH ANTIBODIES TO HIV.PREDICTING VALUE.CLINICAL SIGNIFICANCE AND LONG TERM FOLLOW-UP VARIATIONS.

B.Clotet.A.Jou.J.Tor.G.Sirera.M.Dominguez.JM Gimeno.M.Foz.
Infectious Diseases Unit.Hospital de Badalona "Germans Trias i Pujol"
Badalona.Barcelona.Catalonia.Spain.

Objective: To assess the value of CD4 and total lymphocyte count follow-up in HIV seropositive patients.

Material: 164 seropositive patients (110 intravenous drug abusers(IDAs);38 homosexuals;16 heterosexuals).No patient had AIDS at entry.CD4 and total lymphocyte count (TLC) were determined each 6 months or before if symptoms developed.Mean follow-up has been 16 months (range 6-48).

Results: Would be shown in tables and figures.

Discussion: There is a trend towards a decline in CD4 and TLC through the follow-up.The decrease in CD4 is more marked in homosexuals than in IDAs.A spontaneous increase in CD4 is ocasionally seen during the first year.Total lymphocyte count should suffice for monitoring the progression of the disease because it mimics the decline in CD4 cell count and is less expensive.IDAs with CD4 cell count at entry below 400 x mm3 subsequently developed AIDS more frequently than patients with CD4> 400 x mm3 at enrollment (p> 0.005). Patients with P.carinii pneumonia (PCP) had in a 95.5% of cases total lymphocyte count below 900 x mm3 and CD4 < 200 x mm3. A total lymphocyte count(TLC) major than 1200 x mm3 rules out PCP.Primary prophylaxis for PCP is required in patients with CD4 < 250 x mm3.

Th.B.P.149 CONSISTENCY OF ROUTINE CD4 +, CD8 + PERIPHERAL LYMPHOCYTE MEASUREMENTS

J.P. Aboulker, B. Autran, K. Beldjord, F. Touraine, H. Tubiana, J.D. Bignon, et al. Groupes INSERM CICLO-T4 et SEROCO, France.

OBJECTIVE : To assess the consistency of routine measurements of CD4 and CD8 lymphocytes in whole blood HIV seropositive samples throughout France using a sample of 12 university laboratories.

METHODS : Two groups of 15 and 12 patients each, with CD4 lymphocytes ranging from 20 to 900/mm³ were tested. Each blood sample was fractionnated into duplicate aliquots (2 x 12) in order that each sample could be tested blindly within each lab during the subsequent 4 hours. Each one to the 12 labs used its own routine method for whole blood IF staining and analysis. In total, among the 12 labs, 3 sources of lysing solutions and of reference FITC conjugated anti-CD4 and CD8 moAbs were assessed and the IF was analyzed on 4 distinct types of cytofluorometers. Total lymphocyte counts were evaluated by both automatic and microscopic hematological methods (7 distinct automatic devices).

RESULTS : A 15 % coefficient of variation was found for overall CD4 cell measurements from 300 to 900/mm³. This weak variability might be mainly attributable to the immunological and hematological devices rather than to the operators or to the reagents.

CONCLUSION : The high consistency and reliability in CD4 lymphocyte counts, required for both clinical and research purposes, can be routinely attained in different laboratories provided automatic counting methods (poor statistical validity of microscopic counts) are used by trained operators during each step of the process.

Th.B.P.150 IMMUNOLOGICAL FEATURES IN HIV-1 POSITIVE PATIENTS: CLINICAL CORRELATION

G.Luzi, I.Mezzaroma, C.Papetti, A.M.Pesce, E.Pinter, M.Cherchi and F.Aiuti
Dept. of Allergy and Clinical Immunology, University of Rome "La Sapienza" Rome, Italy

Objective To describe immunological features during HIV-1 infection.

Methods IL-2 and -IFN production, IgG subclass "in vitro" synthesis as well as routine assays (abs number of T lymphocyte subsets, skin test, WBC count, serum immunoglobulins) have been evaluated in infected patients. 700 subjects belonging to various at risk categories were selected from 2019 individuals: 100 were diagnosed CDC-II and 490 CDC-III.

Lab results Total T cell number was constantly diminished in the terminal stages of AIDS and CD4+ cells were significantly reduced (p<0.01) in 42% of asymptomatic patients, 56% of PGL and 97% of ARC. AIDS patients showed defective "in vitro" response to PWM, production of IL-2 and -IFN induced by specific stimuli. NK from BPMC showed decreased activity in AIDS and ARC.

Clinical results At least two subgroups of seropositive patients may be included in CDC-II and III classified subjects: those showing no immunologic abnormalities and those with one or more immunological alterations.

Conclusions Unknown co-factors may be involved in the clinical evolution of seropositive patients: their relationship with immunological parameters is a central point for a better knowledge of HIV-1 infection.

Th.B.P.151 IMMUNOLOGICAL PARAMETERS OF HIV1 AND HIV2 SEROPOSITIVES

Le Guenno,Bernard;Sarthou J-L.
Institut Pasteur de Dakar,Dakar,Senegal.

Objective: To compare immunological consequences of HIV1 and HIV2 infections in a West african population

Methods: Serological screening was done using HIV1and HIV2-specific ELISA and confirmation by specific Western Blotting(Diagnostics Pasteur) . Analysis of lymphocytes sub populations was done on a EPICS flow cytometer using fluorescein labelled monoclonal antibodies.IgG and IgM were quantitated by radial immunodiffusion, IgE by a sandwich ELISA test and the B2 microglobuline using a competitive ELISA test (all reagents from Behring) .Immune Circulating Complexes were also tested by ELISA (Immunomedics)

Results: Comparison of data from seronegatives , asymptomatic seropositives and AIDS cases showed that B2m and absolute count of T4 cells were the more significant markers of evolution. Comparison of HIV1 to HIV2 asymptomatic seropositives and HIV1 to HIV2 clinical cases showed no difference in the studied parameters.

Conclusion: Perturbations of immunological parameters are the same in our HIV1 and HIV2 infected cohorts and cannot explain differences observed in incubation time and evolutivity of the diseases due to these 2 viruses.

Th.B.P.152

Th.B.P.153 RELATIONS BETWEEN DISTRIBUTION PATTERNS OF LEU8± SUBSETS AMONG CD4± AND CD8± T-LYMPHOCYTES IN THE PERIPHERAL BLOOD

Thiele, Bernhard; Kunze, R.O.F.; Krasser, R.; Trinkler, P.; Ehm, I; Pauli, G.
Abt. Virologie des Robert Koch-Instituts und AIDS-Zentrum, BGA Berlin

The CD4- and CD8 cell number and the resulting CD4/CD8 ratio is still the most valuable parameter to assess the cellular immune status during HIV-infections. Both lymphocyte populations are heterogenous with respect to functional activity and other surface markers. We analysed the coexpression of either CD4 or CD8 with Leu 8 in the peripheral blood of 45 HIV-infected persons. Lymphocytes were isolated from blood by density-gradient centrifugation, stained with fluoresceinated Leu 3a (anti-CD4) or Leu 2a (anti-CD8) antibodies together with phycoerythrin-labelled Leu 8 antibodies and then measured on a FACScan flow cytometer. Irrespective of the clinical stages of HIV infection Leu8+ subsets behave differently in the $CD4^+$ and the $CD8^+$ populations. The shifts in the $CD4^+$lymphocyte percentages strongly correlate with $Leu8^+CD4^+$ cells (r=0.98) but not with $Leu8^-CD4^+$ cells (r=0.03). On the contrary, the changes in the number of $CD8^+$ lymphocytes are almost exclusively caused by $Leu8^-CD8^+$ cells (r=0.91) but not by $Leu8^+CD8^+$ cells (r=0.1). Furthermore, the serum levels of shedded CD8 molecules correlate well with the $Leu8^-CD8^+$ subset (r=0.77) but not with $Leu8^+CD8^+$ (r=0.1).
The observed relations let us assume that the recruitment of different subsets from lymphatic organs is heavily altered already during early stages of HIV-infection.

Th.B.P.154 PREDICTION OF CD4/CD8 RATIOS FROM SERUM PARAMETERS

Kunze, R. O. F.; Thiele, Bernhard; Krasser, R.; Trinkler, P; Beck, A; Pauli, G.
Abt. Virologie des Robert Koch-Instituts und AIDS-Zentrum, BGA- Berlin
FEDERAL REPUBLIC OF GERMANY.

The CD4-and CD8 cell number and the resulting CD4/CD8 ratio still belong to the most valuable parameters for monitoring the cellular immune status of HIV-infected subjects and to assess disease progression. Usually, the CD4/CD8 ratios are obtained from freshly isolated peripheral blood lymphocytes. As an alternative, we tried to predict CD4/CD8 ratios from serum immune parameters. Blood and serum samples were collected from 49 persons, 39 of which were HIV-positive and belonged to the stages asymptomatic, LAS, ARC. In a multiple regression analysis 30 parameters, among them percentages of CD4 and CD8 cells, neopterin, β_2- microglobulin, the immunoglobulins G, A, M, the immune complexes C1q, C3b, IgG, IgA, IgM, autoantibodies against the lymphocyte surface antigen CD5 (aab-CD5), soluble CD8 antigen (sCD8), and soluble interleukin-2 receptor were proved for their usefulness to predict the CD4/CD8 ratio. The best result (r=0.88) was obtained with a linear combination of only two parameters, aab-CD5 and soluble CD8 antigen irrespective of the clinical stage. This method offers the possibility to estimate CD4/CD8-ratios from stored sera retrospectively.

Th.B.P.155 CORRELATION OF IN VIVO CELLULAR IMMUNE WITH CD4 NUMBER AND DISEASE PROGRESSION IN HIV SEROPOSITIVE PATIENTS

Birx, Deborah*; Rhoads, J.*; Tramont, E.*; Oster, C.*; Burke, D.*; Redfield, R.*. *Walter Reed Retroviral Research Group. Rockville, MD, U.S.A.

Objective: 1) evaluate in vivo cellular immune function in HIV seropositive patients, 2) determine its correlation with circulatory CD4 (+) cells, and 3) determine its ability to predict HIV disease progression.

Methods: 1555 anergy panels and simultaneous CD4 counts were performed in 1000 patients. The anergy panel consisted of 0.1cc ID injection of tetanus tox. (0.1Lf, 1.0Lf), candida alb. (1:10, 1:100 w/v); mumps 40CFU, and trichophyton (1:30) w/v. 300 of the 1000 patients have been followed serially for 24-54 months and observed for HIV disease progression.

Results: Antigen reactivity	(n)	(%)	CD4 (#/MM3) +SD
0/6 (anergy)	215	14	109+127
1/6	166	11	259+162
2/6	247	16	388+199
3/6	251	16	497+223
4/6	240	15	577+265
5/6	290	19	685+351
6/6	146	9	787+361

Antigen responsiveness significantly correlated with CD4 number R=0.95. Progressive loss of antigen reactivity independently correlated with HIV disease progression to opportunistic infection.

Conclusion: This panel provides a clinical parameter that correlates with absolute CD4 number and is independently predictive of HIV disease progression and development of opportunistic infection.

Th.B.P.156 HIV-2 INFECTION AND IMMUNODEFICIENCY

Lisse, I*; Poulsen, Anne-Grethe**; Aaby, P.***; Kvinesdal, B.B.**; Mølbak, K.**; Dias, F.**** and Lauritzen, E.**
*Hvidovre Hospital, Copenhagen, Denmark, **Statens Seruminstitut, Copenhagen, Denmark, ***University of Copenhagen, Copenhagen, Denmark, ****Laboratorio Nacional de Saude Publice, Bissau, Guinea-Bissau.

Objective. To evaluate the effect of HIV-2 infection on T-Helper cell numbers and T-Helper/T-Suppressor ratio (H/S).

Methods. Forty-seven HIV-2 seropositive adults identified in a cross-sectional community study in Bissau 1987 were re-examined after 10-12 months follow-up, as were 87 controls matched for age, sex and civil status. A physical examination was done. Heparinized capillary blood was collected, and the same day WBC and blood smears were made. One blood smear was fixed in methanol for differential counting; the others were stored at -20°C until labelled by immuno-alkaline phosphatase technique (APAAP), using monoclonal antibodies against T-Helper and T-Suppressor cells.

Results.	HIV-2 seropositives	Controls	p-value
T_4-cells $\leq 0.4 \times 10^9/l$	7/47	2/87	<0.02
H/S ≤ 0.8	16/47	7/87	<0.0005
T_4-cells $\leq 0.4 \times 10^9/l$ and H/S ≤ 0.8	6/47	0/87	<0.005
T_4-cells $\leq 0.4 \times 10^9/l$ or H/S ≤ 0.8	17/47	9/87	<0.00015

Conclusion. HIV-2 is significantly associated with low T-helper cell numbers and inverted T-Helper/T-Suppressor ratios.

Th.B.P.157

Th.B.P.158 EVOLUTION DES DIFFERENTES SOUS-POPULATIONS CD4 et CD8 AU COURS DE L'INFECTION PAR LE VIRUS HIV-1.

Arras, Marcella; Piras, S.; Pintus, A.; Piro, S.; Salis, E.; Cossu, L.
Chaire de Génétique Médicale; Université de Cagliari, Cagliari, Italie

La cytométrie à flux en deux couleurs et l'emploi d'anticorps monoclonaux spécifiques pour les antigènes T3, T4, T8, 2H4, 4B4, Leu18, Leu7, Leu11 et DR, nous permettent de définir un grand nombre de sous-populations lymphocytaires. Ont étés étudiés 20 contrôles adultes sains et 100 individus HIV-1 séropositives, dont 30 séropositives asymptomatiques (SPA), 30 avec lymphoadénopathie généralisé persistente (PGL), 20 avec ARC et 20 avec SIDA.

La diminution progressive des lymphocytes CD4 dans les étapes de SPA, PGL, ARC et SIDA concerne toutes les sous-populations CD4 positives, mais dans les cas de PGL elle est due essentiellement à une chute du subset 4B4, le subset 2H4 étant presque normal, alors que dans les cas de SPA, de ARC et de SIDA les deux subsets 4B4 et 2H4 chutent parallelement. Il faut remarquer la presence d'un pourcentage variable de cellules qui coexpriment 4B4 et 2H4 chez le sujets avec SPA, PGL ou ARC. Ceci peut-être due à l'activation immune des lymphocytes CD4 par le virus. Les lymphocytes CD8 augmentent dans les SPA, les PGL et dans une partie des ARC. L'augmentation est due essentiellement à une sous-population definie par une haute densité de l'antigène CD8 ($CD8^{HD}$) avec phénotype CD3+ Leu11-. La coexpression ou non de l'antigène Leu7 délimite deux subsets $CD8^{HD}$, CD3+ Leu11- Leu7- et $CD8^{HD}$, CD3+ Leu11- Leu7+. Le premier prévaut nettement dans les contrôles. Par contre dans les SPA et le PGL les deux subsets augmentent mais surtout le subset $CD8^{HD}$, CD3+ Leu11- Leu7+, et le rapport entre eux est inversé. Le passage à l'étape de ARC et surtout de SIDA est marqué par une chute progressive des cellules CD8 (avec hausse relative) due essentiellemente a une diminution du subset $CD8^{HD}$, CD3+ Leu11- Leu7+. Il est encore à signaler que des subsets $CD8^{ID}$ (à densité intermediaire) et $CD8^{LD}$ (à basse densité), ont étés observés seulement chez les sujets HIV-1+. La signification des variations observés dans les subsets des cellules CD4 et CD8 est discuté en fonction de l'évolution clinique de l'infection retroviral vers le SIDA.

Th.B.P.159 IMMUNOLOGIC ABNORMALITIES OF SEROPOSITIVE AND NEGATIVE GAY MEN

Fletcher, M.A., Klimas, N.G., Ironson, G. Laperriere, A., Schneiderman, N. University of Miami Center for the Biopsychosocial Study of AIDS, Miami, FL, USA.

Objective To determine the early immunologic effects of HIV infection in healthy gay men and to compare immunologic status of gay men to age and sex matched controls.
Methods Markers of cellular immune function were determined for 56 healthy gay men, 39% anti-HIV-1 positive (+), enrolled in a longitudinal study, and 25 age and sex matched controls.
Results The (+) gay men in this study did not differ from the (-) gay men or the controls in total number of lymphocytes, CD2 cells, CD2+Ta1+ cells, cells of the inducer subset, CD45r+CD4+, or CD20 cells. The number of CD4 cells, as well as the helper subset, CDw29+CD4+, were significantly depressed in (+) men when compared to the controls or to (-) gay men. CD4 cells in these latter two groups did not differ from each other. CD8 cells were elevated in the (+) men as compared to either (-) group, and there was a greater proportional increase in I2+CD8+. CD4/CD8 was 1.3 in the (-) gay males, significantly higher than the (+) group (0.7), but also significantly lower than the controls (1.8). The ratio CDw29+CD4+/ I2+CD8+ cells was 1.9 for the (+) men, 4.8 for the (-) gay men and 5.7 for the controls. There was a significant elevation of NKH.1+ cells in both groups of gay men as compared to controls. The mean response to both T cell and T/B cell mitogens of the (+) men was one-half that of the (-) gay men and one-fourth that of the controls. Natural killer (NK) cytotoxicity was similar for both groups of gay men; both were significantly lower than the (-) control group.
Conclusions Early immunologic changes which may be related to HIV-1 infection were decrease in the helper subset of CD4 cells, elevations in CD8+I2+ cells and NKH.1+ cells and marked depression of lymphocyte response to mitogens. AntiHIV-1 (-) gay males had decreased mitogen responses and NK cell activity compared to controls. (Supported by NIMH 1P50 MH42455)

Th.B.P.160 DEPLETION OF CD16 NK CELLS IN HIV INFECTION DUE TO A SELECTIVE DECLINE IN THE $CD16^+CD8^+$ COMPARTMENT.

Mansour, I*; Doinel, Christian*; Bourin, Ph*; Lefrère, J.J.*; Meyohas, M.C.**; Rouger, Ph.* and Salmon, Ch.*.
* Institut National de Transfusion Sanguine, Paris, France.
** Hôpital Saint-Antoine - Service des maladies infectieuses, Paris, France.

Objective. To analyse the Natural Killer (NK) cells in HIV-infected patients.
Methods. Using monoclonal antibodies and two-color flow cytometric analysis, we analysed the NK cell subsets in 121 HIV-infected patients (53 CDC II, 31 CDC III and 37 CDC IV : 6 IVA, 2 IVB, 15 IVC_1, 5 IVC_2, 2 IVE and 7 IVD) and 50 healthy controls.
Results. The CD16 NK cells showed a depletion in all stages of HIV infection compared to controls. The mean count and the mean percentage in stage II, III, IV and controls were respectively : 191 cells/mm^3, 10%, $p < 0.001$; 167 cells/mm^3, 9%, $p < 0.001$; 123 cells/mm^3, 9%, $p < 0.001$; 276 cells/mm^3, 15%. Using the presence of the CD8 surface antigen on CD16 cells as a discriminating criteria, we analysed two subsets : $CD16^+CD8^-$ and $CD16^+CD8^+$. The $CD16^+CD8^-$ cells showed no statistically significant difference in all HIV infection stages compared to controls, whereas the $CD16^+CD8^+$ cells showed the same profil of depletion as the total CD16 cells (57 cells/mm^3, 3%, $p < 0.001$ in stage II ; 35 cells/mm^3, 2%, $p < 0.001$ in stage III ; 31 cells/mm^3, 2%, $p < 0.001$ in stage IV ; 111 cells/mm^3, 6% in controls).
Conclusion. We observed a depletion of the CD16 NK cells early in HIV infection. It seems that only the $CD16^+CD8^+$ subset accounts for this depletion and not the $CD16^+CD8^-$. The etiology of this selective depletion is still unclear.

Th.B.P.161 AIDS PREDICTORS

Sher, Ruben.
Department of Immunology, School of Pathology, University of the Witwatersrand and the South African Institute for Medical Research, Johannesburg, South Africa.

OBJECTIVE. To evaluate and compare serum β2-microglobulin (β 2-micro) levels, IgA and CD4 lymphocytes as predictors of AIDS.
METHODS. 824 patients were studied for HIV-1 infection in Johannesburg by testing for the presence of HIV-1 antibodies and their immunological status. CD4 lymphocytes were counted using a cytotoxicity assay, β 2-micro was measured using the Pharmacia β 2-micro RIA test and IgA by turbidimetric methodology.
RESULTS. Of the 824 patients studied, 504 (61%) were exposed to the HIV and 74 (14.7%) developed AIDS. Sixty seven (90.5%) of the AIDS cases had elevated levels of β 2-micro and 33 (44.6%) had elevated levels of β 2-micro, IgA and decreased numbers of CD4 lymphocytes ($< 400 \times 10^3$ /1). Fifty three (71.6%) had elevated β 2-micro levels and decreased CD4 lymphocyte numbers while 37 (50%) had both elevated levels of β 2-micro and IgA. β 2-micro levels were elevated in 34 (50.7%) of the 67 AIDS cases prior to them developing AIDS. The remainder were assessed when they already had AIDS.
CONCLUSION. 1) elevated levels of β 2-micro were shown to be the most consistent predictors for AIDS and usually indicated a poor prognosis.
2) The possible use of elevated β 2-micro as an indicator for the initiation of prophylactic AZT requires evaluation.

Th.B.P.162 DICHOTOMY OF TWO $CD8^+$ LYMPHOCYTE SUBSETS IN HIV-INFECTED PATIENTS - Depletion of $CD8^+CD3^-$ and expansion of $CD8^+CD3^+$ subsets.

Mansour, I.; Doinel, Christian; Bourin, Ph; Roquin, H.; Lefrère, J.J. and Rouger, Ph.
Institut National de Transfusion Sanguine, Paris, France.

Objective. To help understanding the expansion of CD8 lymphocytes in HIV infection.
Methods. We analysed two CD8 subsets : $CD8^+CD3^-$ and $CD8^+CD3^+$, using monoclonal antibodies and two-color flow cytometric analysis in 120 HIV-infected patients (52 CDC stage II, 31 stage III, and 37 stage IV) and 50 healthy controls.
Results. In HIV-infected patients, we observed a depletion of the $CD8^+CD3^-$ subset and an expansion of $CD8^+CD3^+$ subset.

	controls(1)	CDCII(2)	CDCIII(3)	CDCIV(4)	Mann Withney U test					
	Mean±SEM				1/2	1/3	1/4	2/3	2/4	3/4
CD8										
%	31±1	55±2	56±2	63±2	*	*	*	NS	**	***
LY/mm^3	578±31	1009±58	945±57	866±78	*	*	**	NS	NS	NS
$CD8^+CD3^-$										
%	8±1	3±1	2±1	2±1	*	*	*	NS	*	*
LY/mm^3	140±14	58±7	42±5	27±3	*	*	*	NS	*	*
$CD8^+CD3^+$										
%	23±1	50±2	52±2	60±2	*	*	*	NS	*	**
LY/mm^3	416±24	928±75	872±58	829±75	*	*	*	NS	NS	NS

LY : lymphocytes; * $p<0.001$; ** $p<0.01$; *** $p<0.05$

Conclusion. The apparent expansion of the total CD8 population in HIV infection is, in fact, the consequence of an increase of the $CD8^+CD3^+$ subset which conceals a severe depletion of the $CD8^+CD3^-$ subset.

Th.B.P.163 COMPARISON OF T4 COUNT, CD4%, AND T4/T8 RATIO WITH CORRELATION TO CLINICAL STAGE OF HIV-1.

Malone, Joseph*; Wagner, KF**; Mayers, DL**; Hendrick, B*; Coffin, ET*; Wilson, DB**. *Naval Hospital, San Diego, CA, USA, **National Naval Medical Center, Bethesda, MD, USA.

Objective. To compare commonly measured T cell parameters, and to correlate results with clinical (Walter Reed (WR-)) stage.
Methods. We measured T cell subsets(T4 count, CD4%, and T4/T8 ratio) from 584 military HIV-1 seropositive patients for up to three years. A total of 1176 samples were obtained, and 318 patients had multiple T cell subsets drawn.
Results. The percentile ranks of each parameter determined separately from the 1176 samples are:

Percentile:	15	30	45	60	75	90
T4 count(cells/mm3) :	200	320	400	480	578	800
CD4% :	14.5	20.0	23.0	27.0	31.5	38.0
T4/T8 :	0.25	0.4	0.5	0.6	0.85	1.2

Using the 15th percentile of the parameters to detect the presence of Walter Reed stage 5 or 6 disease in the 1176 samples:

Criteria:	sensitivity:	Positive predictive value:	P value(Chi Sq.):
T4 < 200:	67%	63%	<0.001
CD4%< 14.5:	59%	56%	<0.001
T4/T8<0.25:	58%	54%	<0.001

The T4/T8 was slightly more predictive of progression to WR-5-6 disease than the CD4% and T4 count when analyzing 33 patients that were WR-1-4 on presentation and progressed to WR-5-6. Conclusion. All three parameters were independently predictive of clinical stage; the first table serves as a comparative index. Clinical staging and prognosis are assisted by these data.

Th.B.P.164 A LONGITUDE STUDY OF LYMPHOCYTE SURFACE MARKERS IN A POPULATION OF 200 HIV + VE intravenous drug abusers (IVDA)

Whitelaw, James,* Bird, G,* Brettle, R.** MacCallum, L* Flegg, P.** Robertson, R.*** *HIV Immunology Lab,** City Hospital,*** Drug Addiction Study Edinburgh, Scotland.

Objective . To observe sequential changes in T Lymphocyte subpopulations in a cohort of 200 HIV+ve IVDA-ve controls over a one year period.
Methods. The cohort was representative of the 500 Edinburgh HIV +ve IVDA, the majority of whom were infected 1983-4. Lymphocyte markers were enumerated by flow cytometry on the same patients at a one year interval.
Results

	CD4+ $/mm^3$	CD8+ $/mm^3$	4/8 Ratio	DR+CD3+ $/mm^3$	Leu2+7+ $/mm^3$
HIV-ve IVDA controls (n=50)	1108	839	1.32	226	230
HIV+ve CDC 2/3 (n=138) Jan 88	698	895	0.78	347	237
HIV+ve CDC 4.1(n=13) Jan 88	488	543	0.89	238	260
Jan 89	325	686	0.49	355	275
HIV+ve CDC 4.1/2/3(n[illegible]4)Jan 88	374	623	0.60	249	242
on zi dovudine therapy Jan 89	154	385	0.40	305	250

Conclusions: All HIV +ve IVDA showed markedly reduced CD4+ cells in comparison to HIV-ve controls. All HIV+ve patient groups showed clear evidence of immunological deterioration as assessed by falling CD4 and rising proportions of DR+T cells over a period of 12 months irrespective of clinical stage.
At 1 year zidovudine therapy did not appear to reverse this trend.

Th.B.P.165 BLOOD AND CEREBROSPINAL FLUID(CSF) LYMPHOCYTE PHENOTYPING(LP) AND HIV-1 p24 ANTIGEN(AG) DETECTION IN HIV-1 INFECTED(HIV+) ZAIRIANS WITH(N+) AND WITHOUT(N-) NEUROLOGIC SIGNS

Brown, Christopher*/**; Quinn, T.**/***; Lubaki, N.*; Perriens, J.*. *Projet SIDA, Kinshasa, Zaire; **National Institutes of Health, Bethesda, MD; ***Johns Hopkins Hospital,
Baltimore, MD.U.S.A.

Objectives. To describe the relationship between BL and CSF AG and lymphocyte subsets in HIV+ N+ and N- patients.
Methods. We determined (Epics Profile) absolute numbers for lymphocytes(LYAB), T4(T4AB), T8(T8AB) and T4/T8 ratio(T4/T8) for BL and CSF samples in HIV+ N+ and N-. Of this population, both had BL and CSF studied. AG was determined by the Dupont kit on both CSF and blood in 69 individuals.
Results. Of 69 patients 6(8%) were BL AG+ and 2(3%) were CSF AG+, however AG was found in the absence of BL AG in both patients.

Status	N+	N-	AIDS+	AIDS-	Dead	Alive
BL AG	5/36(14%)	1/35(3%)	2/22(9%)	4/49(8%)	3/32(9%)	3/39(8%)

Status	BLLYAB	BLT4AB	BLT4/T4	CSFT4/T8
WB	1997	618	2.7	3.2
WB+	1285	147	0.3	0.16
WB+N+	897	78	0.24	0.14
WB+N-	1557	209	0.36	0.19

Conclusion. AG prevalence in BL and CSFd is remarkably low in WB+ patients in Zaire and more common in those with N+. In this sampling, WB+ patients CSF T4AB levels and T4/T8 ratios were markedly depressed regardless of clinical status.

Th.B.P.166 T AND B LYMPHOCYTE SUBSET DISTRIBUTIONS WITHIN CLINICAL STAGES OF HIV-1 INFECTED PATIENTS

Leyacher, Maryse*; Tallet, S.*; Hulstaert, F.**; Lowder, J.**; Pocidalo, J. J.*
*Hopital Claude Bernard, INSERM U13, Paris, France, **Becton Dickinson Immunocytometry Systems Europe, Erembodegem, Belgium.

Objective. To determine whether flow cytometric analysis of of lymphocyte subsets can be used in staging HIV-1 infected patients.
Methods. Five groups of CDC classified (I: HIV-1- [n=34], II: HIV1+ asymptomatic [n=27], III: lymphadenopathy syndrome [n=26], IV: ARC [n=25], and V: AIDS [n=29]) patients, none of whom had received treatment specific for their illness, were assessed using two color immunophenotyping of their peripheral blood lymphocytes with a lysed whole blood method and flow cytometric analysis with a FACScan cytometer. Included in a larger panel of antibodies, were Leu 4(CD3)/HLA-DR, Leu 3(CD4)/Leu 8, Leu 18(CD45R)/Leu 3, Leu 16(CD20)/Leu 8, Leu 16/Leu 20, and Leu 21/Leu12(CD19).
Results. An increase in the Leu 4+/DR+% was seen when comparing uninfected to infected cases (I: 9.0% SD=3.6, II: 28.8% SD=13.4, III: 38.0% SD=14.5, IV:41.4% SD=12.8, and V: 40.2% SD=16.4). The fall in %CD4+ cells seen from Group I through V (I: 40.6%, II: 24.3%, III: 21.4%, IV: 11.9% and V: 10.2%) was not disproportionally distributed among the Leu 8 or Leu 18 defined compartments. The % B cells, as defined by CD19+ or 20+ did not vary significantly among the five groups (9.2-11.1%), nor did the subsets defined by Leu 21(%+ of B cells = 44-59%) or CR2 (%+ of B cells = 26-31%). The fraction of B cells expressing Leu 8 fell from 90% in Group I to 57-69% in the infected groups.
Conclusion. The increase in Leu4+DR+ cells was consistent with an increased state of T lymphocyte activation in HIV+ patients, however the broad range precluded a further significant definition of subsets of infected patients. Non-selective depletion of CD4+ cells suggests no subset related increased sensitivity to infection with HIV. The B cell defect in HIV infected patients is not defined by expression of activation markers or by depletion of peripheral blood B cells out of proportion to the total lymphocyte count.

Th.B.P.167 APPEARANCE OF T CELLS OF INTRATHYMIC PHENOTYPE ($CD3^+$ $CD4^+$ $CD8^+$) IN THE PERIPHERAL BLOOD OF A PATIENT WITH AIDS.

BASELER, MICHAEL*, Urba, W.*, Budzyn, C.*, Stevens, R.*, Kasper, J.*, Psallidopoulos, M.°, Lane, H.C.+. *PRI, Frederick, MD; +LIR, NIAID, NIH, Bethesda, MD; °Georgetown University, Washington, D.C. U.S.A.

Objective. Characterization of a unique T cell line isolated from a patient with AIDS and Kaposi's sarcoma.
Methods. Phenotypic analysis was performed utilizing standard flow cytometry and lymphocytes were purified by cell sorting. Cell lines were established in IL2-containing media and T cell receptor genes examined by Southern hybridization. Lymphocyte proliferative responses to standard mitogens and antigens were measured. Gene amplification utilizing the polymerase chain reaction was performed.
Results. A patient was identified whose peripheral blood contained a unique population of cells that was $CD3^+$ $CD4^+$ $CD8^+$, suggesting that it was at an early stage of T cell differentiation. Retrospective analysis revealed that this population had expanded from 56% of peripheral blood cells (PBLs) to > 75% of PBLs over 2 years. As this population expanded, the responses of the patient's PBLs to mitogens and antigens decreased. An IL2-dependent cell line was established that was $CD3^+4^+8^+Dr^+TcR^+$ and $IL\text{-}2R^-$. Southern blot analysis of this cell line did not reveal a monoclonal expansion of cells. PCR utilizing a primer pair from the HIV gag region indicated that the cells harbored the HIV genome.
Conclusions. A patient with AIDS has been identified who exhibits a polyclonal expansion of immature T cells which contains the HIV genome. These cells do not express mature T cell function and are not killed by HIV.

Th.B.P.168 KINETICS OF ACTIVATED T LYMPHOCYTES (CD3/DR+), NK CELLS (Leu7+/2-) AND "UNSTAINED CELLS" IN THE COURSE OF HIV INFECTION.

Bogner, Johannes R. Matuschke A, Heinrich B, Füeßl HS, Goebel F-D; Universität München, Med Poliklinik, FRG

OBJECTIVE: To determine the lymphocyte subsets of Leu4+/DR+, Leu7+/Leu2- and unstained cells (UNST) (detectable neither by T- nor B-cell markers) in different stages of HIV infection.
METHOD: Peripheral blood from 20 healthy controls and 100 HIV+ patients was prepared and stained with anti LeuM3, -Leu2, -Leu3, -Leu4, -Leu7, B1 and HLA DR. Two colour flow-cytometric analysis was performed on a FACSCAN cytometer. All patients were classified according to WR classification.

RESULTS:		healthy	WR1	WR2	WR3	WR4	WR5	WR6	WR6prefin
n=		20	19	20	11	9	12	21	8
Leu4+/DR+	%PBMC	11.7	21.1	33.8	31.9	35.7	28.4	28.8	21.2
p			<0.01	<0.02	n.s.	n.s.	<0.10	n.s.	n.s
Leu7+/2-	%PBMC	7.0	8.7	7.6	7.5	5.6	6.1	5.6	3.4
p			WR1 vs WR6 prefin p<0.10 (n.s.)						
UNST	%PBMC	15.6	10.7	9.7	13.4	13.9	20.5	21.8	31.0
p							n.s.	n.s.	n.s.

CONCLUSION: Activated T lymphocytes are already significantly expanded in early asymptomatic stages of HIV infection. Activation of T Lymphocytes precedes CD4 depletion. Cytotoxicity against CD4+ cells might be enhanced by Leu7+/DR+, known to be CD8+ cells (Stockholm 2033). In contrast, NK cells show no early change and UNST show a trend to increase in WR5 and 6.

Immunologie : réactions immunitaires
Immunology: Antibody Responses

Th.B.P.169 DENSITOMETRIC ANALYSIS OF HIV1 SEROLOGY ON IMMUNOBLOTTING : PRONOSTIC INTEREST.

RITTER JACQUES,ESCAICH S,CHEVALLIER P,TREPO C,SEPETJAN M.
LABORATOIRE de SANTE PUBLIQUE, LYON, FRANCE.
INSERM U271,LYON,FRANCE.

Objective: To quantify the anti-HIV antibody reactivity on immunoblotting in relation to clinical stage.
Methods: We have studied 450 sera between october 1988 and january 1989, with anti P18/P24 antibody assay (recombinant antigen EIA, Abbott), HIV antigenemia (EIA, Abbott) and scanning densitometry on immunoblotting (Biorad). The same pool of sera was used in each immunoblotting assay as external standard. Results are expressed in percentage of external standard reactivity.
Results: Antiglycoprotein antibodies (GP 160 and GP41) and anti POL gene products antibodies (P66 and P32) variations did not correlate with any clinical feature (Stages II, III, IVA and IVC1/IVD from the CDC classification). Anti core protein antibodies exhibit a moderate (P18 and P55) or a high (P24 and P40) correlation with clinical stage.Mean anti P24 reactivity was 22% in AIDS, 31% in ARC and 54% in asymptomatic patients.
conclusion:We confirm the decrease of anti core protein antibodies reactivity with disease progression. A retrospective and prospective study will confirm the pronostic interest of this method compared with other markers: HIV antigenemia, CD4+ lymphocyte numeration.

Th.B.P.171 SECRETORY AND SYSTEMIC IMMUNITY IN HIV-INFECTED INDIVIDUALS

Sun, Di; Furth, P.; & Archibald, D.
University of Maryland at Baltimore, Baltimore, MD, U.S.A.

The secretory immune response to HIV has been proposed to play a role in viral transmission of HIV. We investigated the oral secretory and serum antibody response to HIV and its relationship to clinical status in 20 randomly selected HIV-infected individuals. By CDC clinical criteria, 7 individuals were in group II, 3 in group III, and 10 in group IV. Parotid saliva and serum were collected and assayed for HIV specific antibodies by immunoblotting. Blots were incubated with saliva or serum, then with a biotinylated anti-human antibody and finally with a streptavidin-biotin HRP complex. Antibodies to HIV env antigens gp160 and gp120 were detected in saliva and serum in all individuals of group II, III and IV. Antibodies to viral core antigens p24, p55 and p17 were detected in 6/7 group II patients (6 with CD4+ counts > 200/mm^3) in both saliva and serum. Antibodies to core antigen were not found in the salivas, but were detected in the serums of 3/3 group III and 10/10 group IV patients (all with CD4+ < 200/mm^3). The difference between group II and group III or IV core antibody detection in saliva was significant (p<0.01). The difference between the presence of antibody to core antigens in saliva and serum was also significant (p<0.001) as tested by Chi-square. The antibody titres to HIV in serum were more than 3,000 times greater than those in saliva (1:1,000,000 vs. 1:300). The range of antibody titres in parotid saliva was 1:3 to 1:300. Decreased secretory antibodies to core HIV antigens may correlate with presence of symptoms and a higher CDC clinical status in HIV-infected individuals. Some independence in systemic vs. secretory antibody response is also suggested.

Th.B.P.173 INDETERMINATE HTLV-I IMMUNOBLOT REACTIVITY IN LOW AND HIGH HTLV-I SEROPREVALENCE GROUPS-PROBABILITY OF RESOLUTION OF INDETERMINATE IMMUNOBLOT RESULTS BY RADIOIMMUNOPRECIPITATION ASSAY.

Hartley,Trudie M., Khabbaz,R., Cannon,R., Kaplan,J., Lairmore,M., Centers for Disease Control, Retrovirus Diseases Br, Atlanta, Georgia, USA.

Objective:Define patterns of indeterminate HTLV-I immunoblot (IB) reactivity in sera from low(e.g.blood donors)and high(e.g.IVDUs) seroprevalence groups, and determine the probability that HTLV-I antibody (Ab) status of sera with these patterns will be resolved by radioimmunoprecipitation assay (RIPA).
Methods: Sera repeatedly reactive by HTLV-I ELISA were tested by IB. Sera with indeterminate (IND) results by IB (those with at least one viral band, but not reactive to both p24 and gp46 or gp61/68) were analyzed by RIPA.
Results: All of the 178 indeterminate IBs studied were gag reactive only: 63 (35.4%) were p19+ p24+, 58 (32.6%) were p19- p24+, and 57 (32.0%) were p19+ p24-. Indeterminate IB reactivity differed in low and high seroprevalence groups: in groups with low HTLV-I seroprevalence (<0.1%), 21/24 (87.5%) were p19+ p24-; in high seroprevalence groups (>2.0%) this pattern was seen in only 3/60 (5.0%) IND sera. Indeterminate IB patterns with p24 represented 3/24 (12.5%) sera in low HTLV-I seroprevalence groups, and 57/60 (95.0%) IND sera from high seroprevalence groups. RIPA detected Ab to any proteins and resolved (confirmed positive) the antibody status of 71/178 (39.9%) of the IB indeterminate sera:44/63 (69.8%) of p19+ p24+ sera, 27/58 (46.6%) of p19-p24+ sera, and 0/57 (0.0%) of p19+p24-sera. Conclusions: Sera reactive only with gag proteins were responsible for all of the indeterminate IB reactivity seen, and the pattern of gag-only reactivity differed with seroprevalence. RIPA detected Ab to any proteins present in low titer in a significant number of IB gag-only reactive sera, and resolved the Ab status of these sera.

Th.B.P.170 CORRELATION OF CLINICAL DIAGNOSIS OF HIV INFECTION WITH THE RESULTS OF ELISA, KARPAS CELL TEST AND WESTERN BLOT FOR ANTI-HIV ANTIBODIES.

Paulino, U.H.M., Greco,Dirceu B.,
Immunodeficiency Clinic,Infectious and Parasitic Diseases Service,Faculty of Medicine ,Federal University of Minas Gerais, Belo Horizonte, BRAZIL

Objective: Correlate the level and type of anti-HIV antibody with the clinical diagnosis of the infection.

Methods: To evaluate 549 individuals examined from February 86 to May 88, we have employed three tests for the detection of anti-HIV antibodies: ELISA, KARPAS CELL TEST and WESTERN BLOT. One hundred sixty two persons(30.6%) were HIV positive. 105 had symptoms: 23 PGL, 50 ARC and 32 had AIDS.

Results: In percentage:

	Asymptomatic	PGL	ARC	AIDS
ELISA(2x cut-off)	76.6	73.9	48.0	34.4
KARPAS(above 1:2560)	21.6	8.7	10.0	6.3
WESTERN BLOT(p24+)	96.7	95.7	82.0	68.7

Conclusion: In our sample the clinical diagnosis of AIDS correlated with low levels of antibodies(Karpas and ELISA) and with the absence of P24 on Western Blot. Routine evaluation of these parameters in the follow up of HIV-positive individuals may be of prognostic value.

Th.B.P.172 IGG SUBCLASS ANTIBODIES AGAINST SYNTHETIC PEPTIDES OF HIV-1 PROTEINS IN HIV-1 INFECTED INDIVIDUALS

Bek, Barbara; Kunze, R.O.F.; Schwartländer, B. and Pauli, G.
AIDS-Zentrum und Robert Koch-Institut des Bundesgesundheitsamt, Berlin, FRG,

Objective. To evaluate the significance of HIV-specific IgG subclass antibodies against synthetic peptides in monitoring HIV infection.
Methods. IgG subclass antibodies were measured in an ELISA using seven synthetic peptides derived from immunodominant regions of gag and env. Sera from patients with AIDS (8), ARC (10), PGL (21) and without symptoms (10) and follow-up sera drawn in intervals of 6 months (follow-up 1,5 to 2,5 years) from 9 patients in different stages and with different clinical outcome, were investigated.
Results. IgG1 and IgG3 were the principle reactive subclasses. A significant lower frequency of IgG3 to all peptides was seen in patients with AIDS. Exept of the N-terminal peptide of gp41, a steadily declining frequency of IgG1 to all peptides was seen with ongoing disease. In follow-up sera little changes in antibody patterns occured, suggesting that an established pattern was maintained. Most changes appeared in IgG3. Multivariate statistics were performed to correlate these findings with other data as CD4/CD8 ratio, ß-2-microglobuline, soluble interleukin-2-receptor and p24 antigen.
Conclusion. Although IgG3 titers showed a significant difference between AIDS patients and patients without AIDS, the subclass antibody pattern in follow-up sera showed no correlation with clinical outcome.

Th.B.P.174 SALIVARY IgA TO HIV IN PATIENTS WITH OR AT RISK OF AIDS

Nagy K.[+], Voevodin A.[++], Drexler E.[+]
[+] Institute of Isotopes, Hungarian Acad. Sci., Budapest, Hungary
[++] Institute of Experimental Pathology and Therapy, Sukhumi, USSR

Objective To analyze the presence and diagnostic value of HIV specific secretory IgA antibodies in saliva of patients infected with HIV, and to compare it to HIV specific IgG level of the serum of the same patient.
Methods Whole saliva samples were collected by expectoration from 15 haemofiliacs (5 adults, 9 children) and 16 homosexual men. HIV specific sIgA were tested in an Elisa using monoclonal antibodies to sIgA (A-5). Serum samples taken at the same time were tested in two Elisas (Organon and Peptoscreen-2) and in a Western-blot assay.
Results In 4 (80%) of HIV seropositive adult haemofiliacs, saliva samples contained HIV specific sIgA. Out of the 9 haemofiliac children 6 were HIV seropositives and 5 (83%) produced salivary antibodies to HIV. Among the 16 homosexual men in 12 cases (75%) we could detect HIV specific sIgA in the saliva (in 33% of AIDS, 66% of ARC and 90% of asymptomatic patients), while all were seropositive. We could not detect salivary antibodies to HIV in seronegative individuals.
Conclusion Finding antibodies to HIV in saliva of patients infected with HIV indicated that the virus is capable of eliciting a response in the intestinal-associated lymphoid system characterized by sIgA antibodies.
As an alternative, saliva may prove useful for rapid HIV antibody testing, first of all in populations in which venipuncture is difficult or contraindicated.

Th.B.P.175 CLASS-SPECIFIC ANTIBODIES TO HUMAN IMMUNODEFICIENCY VIRUS-1 (HIV) IN SMALL INTESTINAL FLUIDS FROM AIDS PATIENTS.

Janoff, Edward M.*,**; Wahl, S.M.* and Smith, P.D.*
*NIDR, National Institutes of Health, Bethesda, MD, **Veterans Administration Medical Center and University of Minnesota, Minneapolis, MN, U.S.A.

Objective. To determine whether HIV elicits antibodies to specific viral antigens in the small intestine.
Methods. Total IgG, IgM, and IgA were measured in serum and duodenal fluids from 10 AIDS patients. Specific IgG and IgA antibodies to HIV were detected using immunoblots of HIV antigens with labeled goat anti-human Ig.
Results. Although appreciable amounts of total IgG, IgM, and IgA were detected in duodenal fluids, only low levels of HIV-specific IgA were found. In contrast, HIV-specific IgG was present in much greater abundance than IgA in duodenal fluids, and the multiple antigens resolved were virtually identical to those detected with serum IgG. By comparison with intestinal antibodies, the predominant HIV-specific antibody in parotid fluids was IgA, not IgG. This IgA recognized multiple antigens.

Unlike specific antibodies, the ratio of total IgA/IgG in duodenal fluids (0.87±.3) was higher than the ratio in serum (0.24±.03; P<0.05), as was IgA/IgM (7.6±1.9 vs 3.7±.6, respectively; P<0.07). In contrast, the ratio of total IgG/IgM in duodenal fluids (15.4±1.7) was similar to that in sera (16.6±8.2).
Conclusions. The predominance of IgG antibodies to HIV in small intestinal fluids, the similar ratio of total IgG and IgM in both intestinal fluids and serum, and the predominance of HIV-specific IgA in parotid fluids suggest that in the proximal small bowel, the exudation of serum and not local antibody production is the major source of antibody to HIV.

Th.B.P.176 *ANTIBODIES TO HUMAN IMMUNODEFICIENCY VIRUS IN SEROCONVERTERS WITH A RAPID TEST.*

Celeste Chenet-Monte and C.H. Riggin, Cambridge BioScience Corporation, Worcester, MA, USA.

Objective. To compare the performance of a rapid latex agglutination assay, Recombigen®-HIV-1 LA (LA), for antibodies to human immunodeficiency virus (HIV-1) to enzyme immunoassay (EIA) and Western blot (WB). Latex agglutination, unlike EIA and WB, is a direct assay for antibodies.
Methods. In order to evaluate the performance of LA, comparisons were made with EIA and WB on five different sets of samples (Boston Biomedica, Inc.) collected longitudinally from plasmapheresis donors who seroconverted for antibodies to HIV-1. These 5 panels have positive samples by EIA and WB which appear in as little as 2 and as much as 50 days after the last negative sample was collected.
Results. LA detected positive samples earlier than or on the same day as EIA and WB on all five seroconversion panels.
Conclusion. LA appears to be particularly well suited for detecting antibodies to HIV-1 of seroconverters; this may be due to the presence of multivalent IgM antibodies. Since LA is based upon cross-linking antigen attached to microbeads with antibodies to form visible aggregates, immune IgM may enhance this particular type of reaction.

Th.B.P.177 DIFFERING SENSITIVITY OF THREE HIV-1 ANTIGEN-CAPTURE ASSAYS TO THE PRESENCE OF HIV-1 ANTIBODY.

Drummond, James E.,[1] Waters, D. J.,[1] Arthur, L. O.,[1] Bess, J. W., Jr.,[1] and Blattner, W. A.[2] [1]Program Resources, Inc., NCI-Frederick Cancer Research Facility, Frederick, MD, USA; [2]Division of Cancer Etiology, National Cancer Institute, Bethesda, MD, USA.

Objective. To determine the effect of HIV-1 p24 antibody in an HIV-1 antigen-capture ELISA.
Method. Three HIV antigen-capture assays; Abbott (A), Coulter (C) and DuPont (D) were compared to determine their ability to detect known quantities of HIV p24 antigen in the presence of antibody to p24. Four HIV-1 whole virus ELISA positive sera (1,2,3,4) were chosen based on their successively greater p24 western blot (WB) reactivity. Normal human sera (NHS) and PBS 1% BSA (PBS) were used as controls. Purified p24 was added to each sample for a final concentration of 10 ng/ml.
Results. Prior to the addition of p24 antigen, sera #1 (weak p24 WB band) exhibited weak-positive reactivity in all three antigen-capture assays. All other samples were negative. After addition of p24, the NHS and PBS samples gave maximum assay reactivity. Sera #1 exhibited a slight decrease in p24 detection in all assays. Sera #2 showed an even greater reduction in detected p24 with wider variation among the three assays. Sera #3 tested negative for p24 antigen in assay A, but was weakly positive in C and D. Sera #4 was weakly positive in assays A and C and still strongly positive in assay D.
Conclusion. Each HIV-1 antigen capture assay exhibited different sensitivities to purified HIV-1 p24 in the presence of p24 antibodies, with as much as 10 ng/ml of p24 remaining undetectable in antibody-positive serum.

Th.B.P.178 DISTRIBUTION OF ANTI NEF ANTIBODIES IN 26 HIV SERONEGATIVE STABLE SEXUAL PARTNERS OF HIV SEROPOSITIVE PATIENTS : EPIDEMIOLOGICAL CORRELATION.

Yves MOUTON*, B.SIVERY*, J.C.AMEISEN***, M.MANIEZ**, C.BEUSCART*, A.CAPRON**
*Department of Infectious Diseases. CHU, **CRTS, ***CIBP Institut Pasteur - Lille. FRANCE.

Objectives : Search for antiNEF antibodies in HIV seronegative stable sexual partners (SMP) of HIV seropositive patients (HIV+P) and epidemiological correlation.
Methods : Structural HIV antibodies were detected by ELISA and WESTERN BLOT(WB). For SMP antiNEF antibodies were detected by RIA. For the epidemiological correlation we have studied the SMP [age, sex, sexuality, yearly number of partners, clinical and immunological status, duration of following up of SMP (DFSMP)] ; their HIV+P [CDC status, P24/25 seric antigen, known duration of seropositivity and/or of illness (DSHIV+P)] and the couple sexuality (safersex or not).
Results : Seventy-two monogamous couples for more than one year were included [32 heterosexual (HTS) and 40 homosexual(HMS)] 19 couples were not evaluable (secrecy=7, conflict in the couple = 4, refusal = 6, other reasons = 2). The study was assessed for 53 couples. 27 partners (51%) are HIV seropositive (8 HTS, 19HMS). 26 partners are seronegative (HIV Elisa, WB negative and P24/25 seric antigen negative). From 26 SMP antiNEF antibodies were detected in 16/26 (61.5%).

	Not evaluable=19	Partners sero+ = 27	SMP NEF+ = 16	SMP NEF- = 10	Total = 72
HTS	7	8	10	7	32
HMS	12	19	6	3	40

For the correlation, the statistical differencies were noted :

	Safersex		DSHIV+P		DFPSN	
PSN	not always	always	>12 months	<12 months	≥6 months	<6 months
NEF+	11*	5	13**	3	13*	3
NEF-	2	8	2	8	3	7

* p<0.05
** p<0.01

Conclusion : The presence of antiNEF antibodies in SMP appeared correlated with the longer known duration of seropositivity of HIV+P and follow up of SMP and with an absence of safersex.

Th.B.P.179 WESTERN BLOT AND PCR REACTIVITY PATTERNS IN INDIVIDUALS AT HIGH RISK FOR HIV EXPOSURE.

Davey, Richard*; Metcalf, J*; Easter, M*; Vasudevachari, V**; Psallidopoulos, M**; Lane HC.*; et al.
*N. I.H., Bethesda, Maryland, USA, **Georgetown University, Washington, D.C., USA.

Objective: To follow high-risk HIV-ELISA negative individuals showing indeterminate Western Blot (WB) patterns for further evidence of HIV infection. Methods: As potential recipients of a candidate AIDS vaccine, 214 homosexual male volunteers between ages 18 and 60 were screened for serologic and virologic evidence of HIV infection. For this study, HIV-ELISA negative individuals with at least a 3 month history of safer sexual practices prior to screening were selected on the basis of a normal medical history, normal immunologic profile, lack of intercurrent illness, and negative HIV culture and serum p24 antigen. Using a WB preparation (Biorad) affording high resolution of HIV envelope proteins, 78 (35.5%) individuals were identified who showed an "indeterminate" pattern of WB reactivity. From this group of 78, a cohort (n=20) was then followed prospectively on a monthly basis using HIV-ELISA, a second WB preparation (Dupont), immunologic profiles, and PCR analysis. Results: Sera from 14/20 (70%) of individuals indeterminate by Biorad WB were also indeterminate by Dupont WB at one or more points in time. Reactivity with the p24 antigen or with the p55 antigen were the 2 most commonly observed WB patterns, each occuring in 7/20 (35 %) individuals. No individual evolved from an indeterminate to a positive WB during a minimum follow-up of one year. By PCR, however, lymphocytes from 7/20 (35%) reacted with at least one primer pair (gag, env, or LTR) at one or more points in time, and 3/20 (15%) showed simultaneous reactivity with at least 2 primer pairs, suggesting the possibility of occult infection. Neither WB nor PCR reactivity necessarily persisted at each longitudinal follow-up. Individual patterns of WB reactivity were not predictive of PCR reactivity.
Conclusions: ELISA-negative, WB-indeterminate individuals at high risk for HIV exposure may show a discordance in serologic and PCR findings over time, with the latter revealing the possibility of HIV infection in some individuals despite failure or delay in WB sero-conversion.

Th.B.P.180 POSITIVE HIV WESTERN-BLOT REACTIONS IN SERUM SAMPLES FROM LED PATIENTS NON INFECTED BY HIV

Dolivo, Nicolas; Bürgisser, Ph. and Frei P.C.
Div. d'immunologie et d'allergie, Centre Hospitalier Universitaire Vaudois, CH - 1011 Lausanne, Switzerland.

Objective. In sera from patients with lupus erythematosus (LED), we have found frequently a partial anti-HIV reaction in western-blot (wb), most often to p24 or p55, more rarely for envelope proteins. The aim of this study is to better characterize this observation and explain its nature.
Methods. 143 serum samples, obtained between 1972 and 1980 (i.e. before first seropositive cases in this area) from 31 patients with LED, were submitted to wb analysis (2 commercial kits) and to different EIAs including one with antigens from noninfected H9 cells. Antilymphocyte antibodies were measured by microlymphocytotoxicity.
Results. A reaction specific for one or more proteins of HIV was found in 51 samples (35%), for p24 (45x), p55 (21x), p18 (9x), gp41 (8x), gp160 (4x), gp120 (3x), p32 (2x). Reactions were shown to be produced by specific IgG and titers were of 1:20 (p24) and 1:4 (p55 and gp41), i.e. about 5x less than in HIV-infected persons. In one patient, the same pattern was present over a 15 y. period. All these samples were negative when tested with recombinant EIAs for HIV gag and env gene products, as well as for HTLV-1. LED samples showing HIV bands in wb reacted in EIA using H9 cells material : x OD 0.345, whereas wb neg LED samples did not : x OD 0.094. Antilymphocytic antibodies were found in 12 of 22 wb pos and in 2 of 13 wb neg samples.
Conclusion : The wb bands "specific" for HIV proteins observed with sera from LED patients noninfected by HIV might be due to antibodies against the H9 cells used to produce HIV material for wb.

Th.B.P.181 HIV-ANTIGEN, VARIOUS ANTIBODIES AND T4 CELL COUNTS AS MARKERS OF CLINICAL PROGRESSION IN HIV-INFECTION

Kleinschmidt, Andrea*; Matuschke, A.*; Schuster, D.**; Schewe, S.*; Mellert, W.***; Prösner, G.G.****; Goebel, F.-D.*; Erfle, V.*** and Hehlmann, R.**
*Med. Poliklinik der Universität München, D-8000 München, FRG; **Klinikum Mannheim der Universität Heidelberg, D-6800 Mannheim, FRG; ***GSF, Abt. für Molekulare Zellpathologie, D-8042 Neuherberg, FRG; ****Max-von-Pettenkofer-Institut, D-8000 München, FRG

Objective. Study of serological markers as to their suitability in clinical prognosis of HIV-infection.
Methods. We have analyzed 600 sera, collected from 145 HIV-infected persons during a five year period, for HIV-antigen, the presence and titers of various antibodies (anti-core, anti-env, neutralizing, anti-nef, anti-RT, anti-rev) as well as the T4 cell counts. The results were correlated with the clinical and immunological (Walter Reed) stages of the patients.
Results. Almost all healthy HIV-infected persons exhibited the full spectrum of antibody reactivity. During the clinical progression the mean anti-p24 antibody titers decrease (LAS-sera: 1:350; AIDS-sera: 1:38) while the p24-antigen levels increase(30% of LAS-sera and 63% of AIDS-sera are positiv). The titers of neutralizing antibodies can be correlated to those of the anti-env antibodies. Using selected patients as examples we show that a change in serological markers precedes clinical progression.
Conclusion. Our results indicate that the combined use of a variety of quantitative antibody, HIV-antigen and T4 cell determinations can also be of prognostic value in individual HIV-infected patients.

Th.B.P.182 Correlation Between HIV-1 p24 Antigenemia, Anti-p24 Antibody and Neutralizing Antibody Response in All Stages of HIV-1 Infection.

P.N. Tsang[1], F.N. Chu[1], P. Mason[1], Y. Sei[1], I. Wallace[1], J.P. Roboz[1], P.S. Sarin[2], and J.G. Bekesi[1]. 1. Mt. Sinai Sch. of Med., NY, NY 10029 USA. 2. NIH-NCI. USA.

The relationship between HIV-1 p24 antigenemia, neutralizing antibody (NA) and anti-viral core protein (p24) Ab was elucidated in the sera of HIV-1 infected individuals during their progression to AIDS. All AIDS patients (N36) and 68% (101/149) of the homosexual males were HIV-1(+). Of these 48 (32%) who were HIV-1(-), 3 sero-converted in 2 years. HIV-1(-) subjects had an early but transient p24 Ag which preceded NA and anti-p24 Ab. After seroconversion, p24 Ag could not be detected. Of the 101 HIV-1(+) subjects 16% rapidly progressed to AIDS and 7 of these 16(44%) died within 2 years. In subjects with poor prognosis, NA and anti-p24 Ab appeared at the onset reaching peak levels just prior to developing AIDS and declined as the clinical course worsened. p24 Ag remained undetectable in sera as long as there was quantifiable NA and anti-p24 Ab. Reappearance of p24 Ag in sera was associated with rapid progression to AIDS. As a result: 12% (11/93) of HIV-1(+) anti-p24 Ab(+), and 63% (5/8) of HIV-1(+)-anti-p24(-) subjects developed AIDS. Of the of HIV-1(+)-p24 Ag(+) subjects 43% (6/14), and 10 of 87 (11%) of the HIV-1(+)-p24 Ag(-) progressed to AIDS. These data suggest (1) an inverse relationship between viral antigenemia and host humoral response, (2) that the presence of both p24 Ab and p24 Ag in sera is of prognostic value, and (3) multifactorial defects in the host's immune surveillance may cause loss of NA leading to increased HIV-1 replication, antigenemia and profound immune dysfunctions in AIDS.

Th.B.P.183 PROSPECTIVE MULTICENTER COHORTSTUDY IN HOMOSEXUAL MEN IN FRG. OBSERVATION OF IMMUNOLOGICAL PARAMETERS IN A 4-YEAR FOLLOW UP

Koch, J.; Schwartländer, Bernhard; Pauli, G. for the Study Group. AIDS-Zentrum im Bundesgesundheitsamt, Berlin, FRG

Objective: To evaluate the correlation between HIV-antibody-patterns (AB), HIV-antigen (AG) and circulating immune complexes (CIC) in the course of HIV-infection.

Methods: In 1984 a prospective multicenter cohortstudy was started in FRG. Of a total of 432 HIV-infected homosexual men 4 groups with typical courses of HIV-infection were selected: Group 1 - 3: individuals without noticeable or slow progression of clinical symptoms in different stages of HIV-infection; Group 4: individuals with rapid progression to AIDS. Cohort members are examined twice a year and specimens are taken for laboratory testing. Antibodies were tested by a peptide-ELISA (5 peptides representing different viral proteins, BIOCHROM) and Western-Blotting. HIV-antigen p24 was measured by capture assays (Dupont and Coulter). CIC were measured after precipitation with PEG.

Results (Selection): Two typical patterns of AG, AB and CIC were seen: individuals with a non progressing stable clinical status (even with ARC) had high titers of AB (slightly decreasing during time of observation), low titers of AG and of CIC. Patients with rapid progression to AIDS had already in the beginning of the observation low titers of AB and CIC, while AG-titers were consistently elevated. These findings may result in additional prognostic markers.

Th.B.P.184 RELATION OF ANTIGENAEMIA,LOSS OF ANTIBODIES TO HUMAN IMMUNODEFICIENCY VIRUS REVERSE TRANSCRIPTASE (RT) AND IMPAIRMENT OF CELLULAR IMMUNITY TO DEVELOPMENT OF AIDS IN DRUG ADDICTS.

Fernández-Cruz, Eduardo; García Montes, M.; Longo, N.; González, B.; Fernández, A. and Zabay J.M.
Division of Immunology.Hospital General "Gregorio Marañón",Madrid, Spain.

We have studied in a prospective follow-up lasting 1 to 39 months, the evolution of HIV infection in HIV-antibody positive I.V. drug addicts (IVDA). Sequential serum samples from 90 IVDA were analysed for antibodies to viral proteins (Lav-blot I) and HIV antigenaemia (ELAVIA AG I). Results were correlated with cellular immune parameters and clinical outcome. Twenty three drug addicts (37%) who showed at the first follow-up visit: a decreased number of $CD4^+$ lymphocytes ($<350/mm^3$), anergy, loss or low level of antibodies to POL proteins (p52 (RT)/p68) and to GAG proteins (p55) and HIV p24 antigenaemia (545±119 pg/ml), had a clinical progression towards AIDS and opportunistic infections (n=20) or a progressive course to the next stage (n=3). In contrast, 40 IVDA (63%) who showed at the first visit: $>350/mm^3$ $CD4^+$ cells, normal delayed hypersensitivity response, presence of antibodies to the viral proteins (p52, p68 and p55) and absence of antigenaemia, had a non-progressive course. Ther were no significant changes in the above parameters throughout the follow-up study in either group. There was no significant difference between the clinical status of the two groups at first visit. Drug addicts with AIDS at the first visit (n=27), showed a substantial lowering of $CD4^+$ cell levels and no significant changes in the others parameters throughout the follow-up. The loss of RT antibody as well as the other above described predictive markers may be early indicators of the progression of virus infection and may have diagnostic and prognostic values.

Th.B.P.185 NEUTRALIZING ANTIBODIES IN HIV PATIENTS: A 3 YEAR FOLLOW UP.

Gesemann, Michael*; Brockmeyer, N.** and Thraenhart, O.*.
*Institute for Medical Virology and Immunology, **Clinic for Dermatology, University of Essen Med. School, Essen, F.R. Germany.

Objective. To study the significance of neutralizing antibodies in the course of HIV infection.
Methods. Fifty one sera from 13 HIV 1-infected patients collected during periods of 10 to 36 months (median 31 months) were tested for their capacity to block HIV infection of H9 T lymphoma cell cultures. After 90 minutes of preincubation at 37°C of different serum dilutions with thawed cell-associated HIV, cells were cultured for 10 days, isolated and evaluated for HIV infection by immunofluorescence. During the study period, lymphocyte counts, T4 and T8 subclasses and beta-2-microglobulin levels were also determined and the clinical status recorded.
Results. Titers of HIV-neutralizing antibodies (NT) ranged from 1:10 to 1:160 and varied by more than factor 2 (1:10 to 1:40) in only 2 persons.

NT	1:10	1:20	1:40	1:80	1:160		
T4 0- 400/mcl	3	0	0	5	5	(n= 3 pat.)	
T4 400-2000/mcl	4	4	20	7	3	(n=10 pat.)	(n=51 sera)

Statistical correlations to beta-2-microglobulin concentrations, T4/T8 ratios or clinical status could not be assessed.
Conclusion. Levels of neutralizing antibodies in 11 of 13 patients were unchanged for a median time of 31 months. Whether these neutr. ab. titers parallel the clinical course or are independent of the clinical status has to be determined by longer follow up and larger groups of HIV patients.

Th.B.P.186 PREVALENCE OF HIV-1 P-24 ANTIGEN (AG) IN DIFFERENT POPULATIONS AT RISK FOR HIV-1 INFECTION IN ZAIRE: A COMPARISON OF THREE COMMERCIAL AG ASSAYS.

Brown, Christopher*; Stibu, L.*; Kline, R.**; Ryder, R.*; Nelson, A.*; Quinn, T.C. ** et al; Projet SIDA, Kinshasa, Zaire;
**NIAID, NIH, Bethesda, MD.

Objective. To determine the frequency of HIV-1 Ag reactivity in selected Zairian (ZR) populations.
Methods. 771 patient sera and serial dilutions of 3 HIV-1 viral culture supernates (vcs) (LAV-01, Z84, Z34) were tested for HIV-1 Ag. 447 sera and the vcs were tested on three commercially available kits (Coulter, DuPont, Abbott). Repeatedly positive samples were considered reactive for Ag.
Results:

Samples	Dupont	Coulter	Abbott
ZR Asx HIV-1 Antibody (+) (n=200)	7 (3.5%)	2 (1.0%)	1 (0.5%)
American AIDS Patients (n=47)	23 (48.9%)	26 (55.3%)	19 (40.4%)

DuPont and Coulter Ag assays detected Ag in vcs at dilutions from 10 to 100 times more dilute than those detected by the Abbott assay. Additional patient samples that tested Ag positive with the DuPont assay included 7 (8.0%) of 88 ZR ambulatory AIDS; 15 (16.9%) of 89 ZR hospitalized AIDS; 6 (17.6%) of 34 ZR AIDS postmortem samples; 5 (12.8%) of 35 antibody-negative clinical AIDS patients; 3 (4.1%) of 74 ZR antibody-negative partners from HIV-1 discordant couples.
Conclusion. In our sampling, HIV-1 Ag prevalence in Zairian patients is lower than in North American patients (P<0.0001), but increases with severity of disease (asymptomatic vs. hospitalized; (P<0.0002). Determination of Ag may aid in the evaluation of disease progression and HIV-1 infection status in high-risk individuals, such as seronegative patients with AIDS-like illnesses and HIV-1 discordant couples.

Th.B.P.187 HIV ANTIGENEMIA IN VARIOUS CLINICAL STAGES OF HIV INFECTION IN AFRICAN PATIENTS.

Van de Perre, Philippe*; Batungwanayo, J**; Lepage, P.** ; and Allen, S.***

* Programme National de Lutte contre le SIDA, Kigali, Rwanda
** Centre Hospitalier de Kigali, Kigali, Rwanda; and
*** Projet San Francisco, Kigali, Rwanda.

Objective: To evaluate the prevalence of HIV antigenemia in various clinical stages of HIV infection in African patients (P.).
Methods: Hundred thirty six consecutive AIDS P. (106 meeting the WHO clinical definition and 30 meeting the CDC definition), 69 asymptomatic HIV carriers and 49 recent (less than 1 month) HIV seroconverters selected among the population of an ongoing cohort study on natural history of HIV infection, were enrolled. They were all tested for HIV IgG by Western blot (WB, Biotech) and for HIV antigen (Ag) by a capture immunoassay (Innogenetics).
Results are summarised in the table:

	HIV WB+	HIV WB p24+	HIV Ag. n (%)
AIDS P.	[illegible]	[illegible]	2 (1.47%)
WHO (n=106)	27	26	0 (0 %)
CDC (n= 30)	116	115	2 (1.5%)
Asymptomatic HIV seropositives (n=69)	69	69	1 (1.4%)
Recent seroconverters (n=49)	49	49	0 (0 %)
TOTAL (n=234)	231	233	3 (1.2%)

Conclusions: HIV antigenemia is unfrequently recovered in African P. with HIV infection, including in those with AIDS and in recent seroconverters. This is probably due to a strong immunological response to HIV gag-encoded proteins. Therefore, HIV antigenemia should not be considered as a useful prognostic marker.
Baillou, A. et al. J Infect Dis 1987; 156: 830-33.

Th.B.P.188 THE SPECTRUM OF ALTERED MENTATION IN AIDS AND ARC

Malouf, Renée*; Jacquette, G.**; Dobkin, J.**; and Brust, JCM*; Departments of Neurology* and Medicine**, Harlem Hospital Center, and the HIV Center for Clinical and Behavioral Studies, Columbia University, New York, U.S.A.

Objective. To assess the prevalence and variety of altered mental status (AMS) among AIDS and ARC patients.
Methods. Neurologic symptoms and signs were prospectively assessed in 190 adult in-patients with AIDS (129) or ARC (61).
Results. 83 (44%) patients had AMS when first seen. 65 were parenteral drug abusers (PDAs), of whom 40 (62%) had dementia and 25 (38%) psychiatric symptoms (PS). Of 18 non-PDAs, 10 (56%) had dementia and 8 (44%) PS. An additional 53 (28%) patients manifested AMS during the course of follow-up. Of these, 28 PDAs had dementia and 11 PS; 4 non-PDAs were demented and 9 had PS. Confusion, memory loss, disorientation, and lethargy were prevalent among the demented. Psychiatric signs included bizarre behavior, depression, suicidal or homicidal behavior, borderline personality, adjustment disorder, mutism, hallucinations (auditory, visual or tactile), paranoia, and conversion symptoms. There was no difference in prevalence of AMS between PDAs and non-PDAs, or between patients with AIDS and ARC. PS however were significantly more common in AIDS than ARC.
Conclusion. Dementia and a wide variety of psychiatric symptoms are frequent among PDAs and non-PDAs with AIDS or ARC.

Th.B.P.189 ACQUIRED IMMUNODEFICIENCY SYNDROME : NEUROLOGIC COMPLICATION IN 44 CASES

Sohler, Puccioni Marzia* ; Favoretto, O. A. C.* ; André, C. * ; Peixoto, C. A. * and Novis, S. A. *
* Federal University of Rio de Janeiro, Universitary Hospital of Rio de Janeiro, Brasil.

Obj.: To study the neurologic complication in patients seropositives for HIV. We studied the clinical records of 200 patients admitted to our Hospital between 1985 and 1988, with a positive Elisa test for HIV. Fifteen percent of these patients exibited clinical abnormalities related of disease of the Central Nervous System. In six patients the neurological complication was the first manifestation of HIV-infection. Patients were mainly male homosexuals, in 30 - 39 age range. Cerebral Toxoplasmosis was diagnosed in 18 instances and meningeal infections were present in 19 cases. Time from appearence of the various neurological complications to death or clinical resolution was almost always shorter than six months. Death was the most frequent outcome, usually ocurring within six months.

Th.B.P.190 ORTHOSTATIC HYPOTENSION (OH) IN HIV+ PATIENTS MAY REPRESENT GENERALIZED AUTONOMIC NERVOUS SYSTEM (ANS) DYSFUNCTION.

Cohen, Jeffrey Allen; Miller L. and Polish L. University of Colorado School of Medicine, Denver, Colorado, USA

Objective. To ascertain if OH may be a feature of more generalized ANS dysfunction in HIV+ patients. Methods. 5 HIV+ patients with severe OH unrelated to medications, infection, or dehydration underwent ANS testing. The ANS testing can be divided into those tests which assess primarily sympathetic: orthostatic blood pressure measurements (generalized sympathetic tone) and Quantitative Sudomotor Axon Reflex Test [(QSART) postganglionic sudomotor function] on the arm and foot. Parasympathetic (cardiac, vagal): heart rate (HR) to responses to deep breathing (DB) and the Valsalva maneuver (VM).
Results. 5 males; 5 gay/bisexual, 1 IVDA; median age 38 years (range 34-49 years); CDC stage: 4 group IV, 1 group III

ANS Abnormalities			Total Group Data
BP △ diastolic	- 5	orthostatic	$\bar{x}$= -15.2 ± 3.7 mmHg
HR △ DB	- 4		$\bar{x}$= 6.6 ± 3.1 BPM
Valsalva Ratio (Max/Min HR)	- 4		$\bar{x}$= 1.3 ± .25
QSART	Arm - 3	Foot - 3	

Conclusions. ANS testing demonstrated both parasympathetic and sympathetic involvement. We conclude that OH may represent generalized ANS dysfunction in HIV+ patients. The OH may be effectively treated; individual patient responses to treatment will be discussed.

Th.B.P.191 POSSIBLE PATHOGENETIC ROLE OF IMMUNE COMPLEXES IN HIV-RELATED AUTONOMIC NEUROPATHY.

Confalonieri Franco, Villa A., Cruccu V., Foresti V., Pariaio E., Scolari N.
Fatebenefratelli Hospital, Milan, Italy.

Objective. To evaluate in a group of drug addicts (DA) the severity of involvement of the autonomic nervous system (ANS) functional tests with respect to CDC groups, to CD4 and CD8 counts and to circulating immune complexes (CIC).
Methods. We studied 46 DA with the ANS functional tests proposed by Ewing & Clarke; 29 were HIV+ (63%) and 17 HIV- (37%). We classified the HIV+ patients (pts) with CDC classification system. CD4 and CD8 counts, CIC IgG, IgM, IgA, C3c and Clq were assessed in all pts.
Results. Only one HIV- subject showed early involvement. Sixty-five percent of HIV+ cases had ANS involvement: 7 (24%) had severe involvement (3 pts CDC group IV, 3 group III and 1 group II); 12 (42%) had early involvement (2 group IV, 7 group III and 3 group II). 10 pts (34%) were normal (6 group III and 4 group II). CD4, CD8 and CIC values, according to the degree of involvement are reported in the table:

ANS test(score)	cases	CD4	CD8	CIC IgG	CIC IgM	CIC IgA	CIC C3c	CIC Clq
HIV+ ≥ 5	7	726	1436	198.2	136.8	7.7	4.1	110.0
HIV+ 2 - 4	12	575	1357	155.5	99.2	6.9	3.6	95.0
HIV+ 0 - 1	10	806	1323	109.7	79.5	4.6	4.0	65.7
HIV-	17	1326	1102	71.1	46.6	3.4	4.6	54.0

Conclusions. The severity of functional ANS involvement is related to CIC increase(IgG and Clq) and it is not related to clinical severity or immunologic failure. This supports the hypothesis of an immune ethiopathology of ANS involvement.

Th.B.P.192 TWO YEARS NEUROLOGICAL FOLLOW - UP STUDY IN HIV-POSITIVE HEMOPHILIACS : DO ANY PROGNOSTIC DATA EXIST ?

Riedel Rolf - Rainer*, Clarenbach P.*, Bülau P.**, Helmstadter Ch.**, Brackmann H.-H.***, Niese D.****, Bruzki Ch.*, Wirtz K.*
* Dept. of Neurology , ** Dept. of Epileptology , *** Institut of Hematology
**** Dept of Medicine ; University Clinic , 5300 Bonn , West - Germany

From October 1986 until Oct. 1988 we examined 28o HIV - seropositive hemophiliacs in WR 1-6. 29.3% = 82 patients attended our clinic thrice or more times . In 1986 38 patients were classified as WR 1 , 35 as WR 2 , 15 as WR 3 -5 , 4 as WR 6 . Two years later the same patients were classified ,too : none as WR 1 , 3o as WR 2 , 28 as WR 3-5 and 14 as WR 6 . Meanwhile 1o WR 6 died . The study covered a neurological status , an EEG and Brain - mapping analysis plus a neuropsychological test : AVLT , CI , Benton , d-2 , MWTB , v. Zerssen , BFS .
We did not observe any specific indicators for the WR 1 patients . In WR 2 - 5 patients we diagnosed the following deficits : isolated nystagmus , gait disturbance , hyperreflexe , cranial nerve lesion , polyneuropathy ; in EEG vigilance oscillations , dysrhythmia , diffuse slowing ; no neuropsychological deficits . Additionally we saw in AIDS - patients sensoric / motoric hemisyndromes , paraspastic syndrome ,subacute encephalitis ; neuropsychological data show a left hemispheric verbal memory deficit .
Our data suppose a progress in history of the HIV - infection by diagnosing a severe vigilance oscillation or a diffuse slowing in EEG ; a gait disturbance or a hemisyndrome / paraspastic in neurological status and a verbal memory deficit in neuropsychological examinations .

Th.B.P.193 INCIDENCE OF THE AIDS DEMENTIA COMPLEX AS THE FIRST MANIFESTATION OF AIDS. A PROSPECTIVE STUDY

Abós J, Graus F, Alom J, Miró JM(*), Gatell JM(*) Tolosa E. Neurology and (*)Infectious Diseases Unit. Hospital Clinic. University of Barcelona. Barcelona. Spain.

OBJECTIVE. To evaluate the incidence of the AIDS dementia complex (ADC) as the first manifestation of AIDS.
METHODS. From August 1987 to September 1988, 102 patients who satisfied the CDC criteria for AIDS were consecutively diagnosed. The clinical diagnosis of ADC was considered in patients who presented with dementia, no previous neurologic or psychyatric disease and no evidence of opportunistic infections or tumors in the central nervous system.
RESULTS. In six patients (5.9%) the presenting manifestation was ADC. None but one of the patients was know to be seropositive before the diagnosis of ADC. The presenting neurologic syntoms included progressive cognitive impairment and motor dysfunction. At the time of diagnosis, HIV-1 serology was positive in serum and CSF. MRI of the head was normal in four patients, in the other two there was focal or diffuse white matter lesions. All patients were immunossupressed with a mean CD4+ cell count of 133 per cc. (range:38-288). Clinical course was characterized by progressive neurologic deterioration. In the two patients who died, the ADC was confirmed at autopsy.
CONCLUSIONS. 1) ADC is the first manifestation of AIDS in 5.9% of the patients and represents an important cause of dementia among young adults. 2) Laboratory evidence of severe immunossupression is invariably present at the time of diagnosis.

Th.B.P.194 MYELOPATHY AS PRESENTATION OF AIDS:TREATMENT WITH AZT.

Caggese,L.; Schiantarelli, Clara; Schlacht, I.; Gasparini, M.; Oreste, P.L.; Villa, M.R.
Niguarda Ca' Granda Hospital, Milan, Italy.

Paraparesis is frequently observed in the end stage of ADC; vacuolar myelopathy is found at autopsy of adult pts with AIDS. We refer here, as rarely reported, on 4 pts in whom paraparesis marked the clinical onset of AIDS.

Since July 1986 to January 1988, 4 males (mean age 27 yrs and drug abuse history) were admitted for myelopathy and HIV infection. They complained of prolonged febrile illness and malaise before appearence of leg weakness in all and urinary retention in 3 pts. The first neurological examination showed hypereflexia, ankle and patellar clonus, Babinski sign and,in 1 pts,also gait ataxia with motor incoordination without sensory levels. All pts had oral candidiasis, mild anaemia,leukopenia, low counts of CD4 cells (mean 34/mm3), expansion of CD8, particularly of CD8+, Leu 7+ subsets. CT scan and/or MRI showed cerebral atrophia in 4/4, periventricular white matter change in 1/4, spinal cord abnormalities in the dorsal tract in 2/4 pts. EEG was altered in all. CSF showed mild elevation of albumin and globulin.Liquor testing for anti-HIV was positive (p 41, p 110,p160 band, Western blot)and negative for anti-CMV,HSV,V-ZV,EBV and toxoplasma.

Two pts developed O.I. (esophageal candidiasis, PCP) and died after 8-12 months whith overt ADC. In 1 of these cases unsuccessful AZT therapy was eventually administered. Gigant cells encephalitis and vacuolar myelopathy were found at autopsy.The 2 other pts are on AZT treatment since admission (12-14 months of follow up): they are free of O.I. but their myelopathy is slowly worsening. Prolonged subclinical illness or different pathogenesis of myelopathy may explain poor response to antiviral treatment.

Th.B.P.195 NEUROPSYCHOLOGICAL FOLLOW-UP OF SUBJECTS ON AZT LICENSING TRIAL: SAN DIEGO COHORT

DAY, Jacqueline* **; Grant, I.**; Atkinson, H.**; Brysk, L.**; McCutchan, J.**, Heaton, R.K. **, et al.
* San Diego State University ** Univ. of California, San Diego, CA, USA

Objective: To document occurrence of dementia in the San Diego cohort of the zidovudine (AZT) licensing trial by 24 month follow-up neuropsychological evaluation.
Methods: Thirty-two ambulatory homosexual men with the acquired immunodeficiency syndrome (AIDS) or advanced AIDS-related complex (ARC) were evaluated prior to starting zidovudine treatment with a comprehensive neuropsychological test battery. Survivors were evaluated at 6, 12, 18 and 24 month intervals with the same battery. In order to minimize practice effects, alternate versions of the tests were employed at follow-up sessions. Diagnosis of dementia was determined according to neuropsychological test performance and DSM-III criteria for dementia.
Results: The table shows the cumulative number of subjects who met criteria for dementia at each follow-up evaluation. The cumulative total of 9 subjects represents 28% of the original sample.

Cumulative Number of Subjects with Clinical Dementia

Baseline	6 Months	12 Months	18 Months	24 Months
0	2	3	6	9

Conclusion: These results are consistent with notions that dementia is a frequent, rather than a rare complication of AIDS.

Th.B.P.196 PERIPHERAL NEUROPATHIES AND HIV INFECTION : SPECTRUM AND NATURAL HISTORY.

Léger Jean-Marc, Bolgert F., Henin D., Rosenheim M., Bouche P., Chaunu M.P., Gentilini M., Hauw J.J., Brunet P.
Hôpital de la Salpêtrière. Paris. France.

Methods : A clinical and electrophysiological study was performed in 29 patients referred for a peripheral neuropathy between November 1984 and June 1988. CSF was examined in 21 cases. A neuromuscular biopsy was made in 12 cases. Follow-up was conducted from 3 months to 4 years.
Results : There were 27 Caucasian and 1 African males (24 homosexual/bisexual), 1 African female, ranging from 27 to 58 years : 1) Six otherwise asymptomatic patients presented an inflammatory demyelinating polyneuropathy (IDP), acute in 1 case and subacute in 5. CSF showed pleocytosis in all cases. In nerve biopsies an infiltration of the endoneurium and/or the epineurium by mononuclear cells, and sometimes microvasculitis, were seen in 3 cases. The 6 patients recovered either spontaneously (4 cases), or with corticosteroids (1 case), or plasmaphereses (1 case). In follow-up from 6 to 48 months, they all have progressed to ARC but none progressed to AIDS. 2) In 5 patients with ARC, we found 1 chronic IDP and 4 distal sensorimotor peripheral neuropathies (DSPN). The neuropathies remained stable, but 2 patients died. 3) Of the 18 patients with AIDS, 2 had a mononeuropathy multiplex and 15 a painful DSPN. EMG studies indicated an axonopathy which was predominant in nerve biopsies in 5/7 cases. Seven patients died within 6 months. The last patient had a polyradiculopathy with lymphocytic meningitis. He died and autopsy found an infiltration of the meninges and the spinal roots by a B-cell immunoblastic lymphoma.

Th.B.P.197 A SYSTEM FOR STAGING THE AIDS DEMENTIA COMPLEX: CORRELATIONS WITH NEUROLOGICAL AND NEUROPSYCHOLOGICAL ASSESSMENTS

Price, Richard W; Brew, BJ; Sidtis, JJ; Sadler, A; Kielp, J; Wolf, W; Birnhak, L. Memorial Sloan-Kettering Cancer Center, New York, NY, U.S.A.

Objective: To assess the utility of a clinical staging system for the AIDS dementia complex (ADC).
Methods: Based on defined criteria of cognitive and motor functional status in daily living, the ADC staging system segregates patients as: 0-normal; 0.5-subclinical or equivocal; 1-mild; 2-moderate; 3-severe; 4-end stage (J. Infect Dis. 158: 1079-1083, 1988). ADC Staging was compared to neurological and neuropsychological assessments in a group of HIV-1-infected individuals at various phases of systemic infection and with various degrees of ADC. Comparisons were made in untreated patients at initial evaluation (n=168), untreated patients including multiple evaluations (n=287), and combined untreated and AZT-treated patients undergoing multiple evaluations (n=473).
Results: ADC Stage was highly correlated ($p<.001$) with salient clinical and neuropsychological assessments in all 3 analyses. For example, at first evaluation, ADC Stage correlated with: clinical cognitive ($r=.77$) and motor ($r=.70$) ratings; clinical ($r=.89$), neuropsychological ($r= .70$) and combined ($r=.84$) impairment scores; ADC-sensitive neuropsychological tests including finger taping ($r=.58$), timed gait ($r=.62$), trail making A ($r=.77$) and B ($r=.70$), grooved pegboard ($r=.71$), digit symbol ($r=.66$), Trial 5 of the Rey verbal learning test (.71) and the Benton visual retention test ($r=.71$).
Conclusion: ADC Staging provides a relatively simple but useful method of patient classification for epidemiological, natural history, pathogenetic, and therapeutic studies as well as for clinical practice.

Th.B.P.198 PHARMACOKINETIC ANALYSIS OF THE ENHANCED DISTRIBUTION OF ZIDOVUDINE INTO RABBIT CEREBROSPINAL FLUID CAUSED BY PROBENECID.

Sawchuk, Ronald J. and Hedaya, M.A.
University of Minnesota, Minneapolis, Minnesota, USA.

Objective. The resolution of AIDS-related neurological dysfunction during zidovudine (AZT) therapy provides a clear rational for the importance of antiviral drug therapy in treating AIDS dementia complex. The objective of this work was to study the kinetics of AZT distribution into the rabbit CSF and to examine the effect of probenecid on this distribution process.
Methods. In this study two groups of rabbits (n=3) received a single IV dose of 10 mg/kg AZT in the absence (control) and presence of a continuous IV infusion of 30 mg/kg-hr probenecid. Plasma and CSF samples were obtained frequently over a period of 3.5 hours, and analyzed for AZT and probenecid by HPLC.
Results. Probenecid coadministration caused a 7-fold increase in the AZT AUC_{CSF} in probenecid-treated rabbits when compared with controls. The AUC_{CSF}/AUC_{plasma} ratio increased from 0.152 ± 0.023 in controls, to 0.568 ± 0.222 in probenecid-treated rabbits. The CSF/plasma AZT concentration ratio during the postdistributive phase increased from 0.24±0.05 in controls to 0.65±0.12 in the probenecid-treated rabbits. A linear pharmacokinetic model, which assumes first-order transfer rates between plasma and CSF, was used to describe distribution of AZT between plasma and CSF. Analysis of intercompartmental clearances showed that the CSF exit rate constant decreased from 0.028±0.01 in control to 0.015±0.006 in probenecid-treated rabbits.
Conclusion. The results indicate that probenecid enhances AZT distribution into the CSF by decreasing its CSF to plasma clearance.

Th.B.P.199 TRANSFUSION-RELATED HTLV-I NEUROLOGICAL DISEASE: A PUTATIVE MARKER OF DISEASE ACTIVITY AND RESPONSE TO THERAPY

Brew, Bruce J; Hardy, W; Poiesz, B*; Ehrlich, G; Larimore, K**; Gold J; Bhalla R; Schwartz M; Price RW. Memorial Sloan-Kettering Cancer Center, NY, *State University of New York, Syracuse, **Centers for Disease Control, USA

Objectives: To report two cases of HTLV-I neurological disease including a putative marker of disease activity, and response to therapy.
Methods and Results: A 65 year old caucasian male, resident in the US, developed HTLV-I associated myelopathy (HAM) 6 months after multiple transfusions for fulminant pancreatitis. Investigations were remarkable for raised concentrations of β_2 microglobulin (β_2M) (Pharmacia, Sweden) greater in CSF than serum. Treatment with azidothymidine and later with plasmapheresis was ineffective, whereas corticosteroids lead to minor improvement. The clinical response to therapy was reflected in a fall in the β_2M concentrations. The second patient, the sexual partner of the first, was transiently positive by ELISA and is now positive only by polymerase chain reaction. Her illness began 3 months after her partner's and consisted of a mild transient peripheral neuropathy.
Conclusions: This is the first documented case of transfusion-related HAM in the US. The changes in CSF β_2M suggest that it may be useful as a marker of therapeutic response. The second case illustrates the difficulties in serological diagnosis and suggests that peripheral neuropathy may be an early manifestation of HTLV-I.

Th.B.P.200 NEUROPSYCHOLOGICAL FOLLOW-UP OF 1787 PARTICIPANTS IN THE MULTICENTER AIDS COHORT STUDY

Visscher, Barbara R.*; Miller, E.*, Satz, P.*; McArthur, J.**; Selnes, O.**; Cohen, B.***; Becker, J.****; English, P.*; and Nance-Sproson, L.**
*University of California, Los Angeles, California; **Johns Hopkins University, Baltimore, Maryland; ***Northwestern University, Chicago, Illinois; ****University of Pittsburgh, Pennsylvania, U.S.A.

Objective: To determine the frequency and severity of neurologic involvement in HIV infection in MACS participants.
Methods: 1787 homosexual/bisexual men were enrolled in the Neuropsychological substudy. 299 were enrolled in Baltimore and 238 in Chicago in 1986, and 209 in Pittsburgh, and 1041 in Los Angeles in 1987. A 25 minute screening battery of neuropsychological (N-P) tests and a 22 item questionnaire on neurologic symptoms were administered at each visit, approximately 6 months apart.
Results:

	% Outliers on N-P Screen				Mean # of Neurologic Symptoms	
Status	N	Visit 1	N	Visit 2	Visit 1	Visit 2
Seronegative	787	2.3	603	1.2	0.6	0.5
Seropositive	616	2.6	439	2.1	1.0	0.7
Seroconverter	122	2.5	77	1.3	1.3	0.65
AIDS	75	8.0	46	10.9	1.9	2.28

Conclusions: Asymptomatic seropositives and seroconverters did not differ from seronegatives on the N-P tests either at Visit 1 or Visit 2. The AIDS group had significantly more failures on the N-P screening tests as well as reporting more neurologic symptoms at each visit.

Th.B.P.201 THE EPIDEMIOLOGY OF AIDS-RELATED NEUROLOGIC DISEASES

Wilson, Mary Jess*; Lemp, GF**; Neal, D**; Payne, SF**; Vlamis, A**; Ferguson DD**; Rutherford, GW.**
*California Department of Health Services and **San Francisco Department of Public Health, San Francisco, California, U.S.A.

Objective. To describe the epidemiology of diseases of the central nervous system (CNS) in AIDS patients in San Francisco (SF).
Methods. We analyzed the demographics and transmission categories of 5834 AIDS cases reported in SF from 1981 through 1988 with respect to CNS diagnoses of toxoplasmosis, primary lymphoma of the brain, progressive multifocal leukoencephalopathy, cryptococcal meningitis, and HIV encephalopathy. Median survival was calculated using the Kaplan-Meier product-limit method.
Results. 415 (7.1%) AIDS patients were initially diagnosed with a CNS disease. CNS diseases as an initial diagnosis rose significantly from 1.9% of total cases in 1982 to 9.4% in 1988 ($p<.001$). 770 (13.2%) AIDS patients had a CNS disease at some point during their illness. The mean age of AIDS patients aged $\geq$ 20 with CNS disease was 39.2 years compared with 37.5 years for persons without ($p<.001$). Heterosexual intravenous drug users were more likely to have a CNS disease (26.9%) than gay men with (15.5%) or without (12.5%) intravenous drug use ($p<.001$). There were no significant differences in gender or race/ethnicity distribution among patients ever having CNS disease vs. those without. Median survival for AIDS patients with CNS disease (6.8 months) was significantly shorter than that for patients without (12.9 months) ($p<.001$).
Conclusion. CNS diseases are increasingly common among AIDS patients. AIDS patients who develop CNS disease are more likely to be older and be intravenous drug users. Survival is shorter for AIDS patients with CNS disease.

Th.B.P.202 NEUROPSYCHOLOGICAL FOLLOW-UP IN PATIENTS WHO HAVE PROGRESSED TO AIDS: THE MULTICENTER AIDS COHORT STUDY (MACS).

Selnes, Ola A.*; Miller, E.N.**; McArthur, J.C.*; Cohen, B.***; Becker, J.T.****; Saah, A.*; Multicenter AIDS Cohort Study, *Johns Hopkins Medical Institutions, Baltimore, MD; **UCLA Neuropsychiatric Institute, Los Angeles, CA; ***Northwestern University, Chicago, IL; ****University of Pittsburgh, PA, USA

Objective: To evaluate changes in neuropsychological (NP) performance in participants in the Multicenter AIDS Cohort Study (MACS) who progressed from asymptomatic (CDC group II/III) to AIDS (CDC group IV).
Methods: Standardized NP testing was available for 76 participants in the MACS Neuropsychological Study who had developed AIDS. Of these, 26 had at least one previous NP evaluation prior to developing an AIDS-defining illness. The performance of those participants was compared with that of 26 age and education matched seronegative (SN) controls. NP testing included tests of attention/concentration, memory and new learning and psychomotor speed, previously shown to be sensitive to HIV-related encephalopathy. Individual performance was classified as impaired if scores on two or more tests were below 2 standard deviations based on SN controls. 10 of the participants with AIDS were taking Azidothymidine (AZT).
Results: The average number of months between initial and follow-up testing was 12 months (range 4.7 - 24.5 months). At the initial visit, 3/26 (12%) participants had impaired NP performance, as compared with 4/26 (15%) at the follow-up visit with AIDS. Comparison of group means at initial and follow-up testing revealed slight, non-significant decline in only 1/6 tests (Grooved Pegboard, non-dominant hand). There was no significant difference between the performance of SN controls and participants with AIDS on any of the NP tests at either visit.
Conclusion: These findings demonstrate that progression to AIDS in this self-selected cohort was not associated with significant decline in cognitive functioning as measured by standardized NP testing. Therefore, although severe immunosuppression may be necessary for the development of HIV-related encephalopathy, it may not be a sufficient condition.

Th.B.P.203 NEUROLOGICAL INVOLVEMENT IN GROUP IV HIV+ PATIENTS: NEUROPHISIOLOGICAL AND CLINICAL DATA.

Mazzotta, Francesco*; Grippo A. **; Di Pietro, M. *; Colao M. G. *; Bartolozzi, D. *; Ghidini, P. **; Pinto, F. **.
*Div. Mal. Infettive Ospedale Careggi; ** Dipart. Mal. Nervose e Mentali Università degli Studi; Regione Toscana. Firenze, Italia.

For purposes of prognosis and therapy, we sought to identify the initial site where HIV begins to exert its deleterion effect. The subjects, all asymptomatic from the neurological point of view, where 8 IVC1 and 20 IVC2 or IVA patients (pts.). The spinal and cortical SEP responsis were recorded during tibial nerve stimulation. The electrophysiological results were compared with clinical assessment and serum and CSF HIV markers. In both groups we observed a slowing of nerve conduction along the entire afferent pathway. While this was not significant at the level of the peripheral nerves, it becames marked and higly significant at the CNS level for about 1/3 of the IVC2 or IVA and for 2/3 of the IVC1 pts.. The major part of the delay occurred in the mid and lower medullary tract. This results agree with neuropathological finding from post-mortem examination of AIDS pts. similar to that described for other lymphotrophic, slow and oncogene viruses. The higher incidence of electrophysiological alterations in the CNS of group IV has already been described in pts. with neurological deficit; however, it has not been satisfactorily documented in neurologically asymtomatic HIV+ pts.. Our findings point to the possibility of using our approach to identify those HIV+ pts. who might best benefit from early treatment.

Th.B.P.204 EFFECT OF MANNITOL IV INFUSION ON DISTRIBUTION OF ZIDOVUDINE BETWEEN PLASMA AND CEREBROSPINAL FLUID IN RABBITS

Wang, Yanfeng; Hedaya, M.A., and Sawchuk, R.J.
University of Minnesota, Minneapolis, Minnesota, USA

Objective. This work was performed to examine the effect of intravenous infusion of mannitol on the penetration of zidovudine (AZT) into the cerebrospinal fluid (CSF) of rabbits, and to study the kinetics of AZT transfer between plasma and CSF.
Methods. Rabbits were assigned either to a control group (n=3), receiving a single IV dose of 10 mg/kg AZT alone, or to a mannitol-treated group (n=4), receiving a single IV dose of 10 mg/kg AZT as well as a continuous IV infusion of 1.5 g/kg-hr mannitol following a bolus of 10 ml/3kg of 25% mannitol. Plasma, CSF and urine samples were obtained frequently over a period of 3.5 hrs, and analyzed for AZT by HPLC.
Results. The results showed that the AUC_{CSF}/AUC_{plasma} ratio increased from 0.152 ± 0.023 in the control rabbits to 0.459 ± 0.089 in the mannitol-treated rabbits. The CSF/plasma AZT concentration ratio during the postdistributive phase increased from 0.24 ± 0.05 in control to 0.68 ± 0.24 in the mannitol treated rabbits. A linear pharmacokinetic model, which assumes first-order transfer between plasma and CSF, was used to analyze the data.
Conclusion. This analysis demonstrates that changes in CSF/plasma AZT concentration ratios caused by mannitol coadminiation can be explained by alterations in intercompartmental clearances of AZT.

Th.B.P.205 CRANIAL NEUROPATHIES IN AIDS PATIENTS

Edwin M. Lewis, S. Mahawar, A. M. Wesley, D. E. Bredesen
UCSF, San Francisco, California, U.S.A.

Objective: To assess the frequency and differential diagnosis of cranial neuropathies in AIDS patients, thereby improving diagnosis and treatment of associated conditions.
Methods: 2370 medical records were reviewed including admissions to UCSF affiliated hospitals from inception of the epidemic through 2/88 (4.3% of all U.S. AIDS cases).
Results: 98 of 2370 patients were diagnosed with cranial neuropathies. The distribution of cranial nerves involved was: 77 seventh, 13 sixth, 13 third, 10 twelfth, 9 fifth, 8 eighth, 3 second, 3 sixth, 2 fourth, 2 ninth and 2 tenth. There was multiple nerve involvement in 33 patients (33.6%).
Probable diagnoses were:

Toxoplasmosis:	34		
AIDS Dementia Complex (ADC):	18	CMV Encephalitis:	4
CNS Lymphoma:	10	Non-Hodgkins Lymphoma:	3
Cryptococcal Meningitis:	10	Bacterial Meningitis:	1
PML:	8	Brain Stem Glioma:	1
Aseptic Meningitis:	4	Cerebrovascular Accident:	1

In addition, 15 had peripheral neuropathies, and 15 had no CNS diagnosis.
Conclusion: 98 patients had cranial neuropathies, 33 of whom had multiple cranial neuropathies. This represents 4.2% of all AIDS patients and 14.4% of neurologically symptomatic patients. Thus, ADC (by far the most common neurological diagnosis) is associated with cranial neuropathy relatively uncommonly, whereas PML and CNS Lymphoma are associated with cranial neuropathy relatively frequently. Although CNS toxoplasmosis is also over-represented, many of these cases occur with upper motor neuron seventh nerve involvement.

Th.B.P.206 NEUROLOGIC ABNORMALITIES AMONG HIV-1 SEROPOSITIVE INTRAVENOUS DRUG USERS

Royal, Walter, III; Cornblath, D.R.; Updike, M.; Selnes, O.A.; Solomon, L.; Vlahov, D.; et. al., The Johns Hopkins Medical Institutions, Baltimore, Maryland, USA.

Objectives: To study HIV-1 related neurologic abnormalities among intravenous drug users.
Methods: All participants are recruited from a natural history study of HIV-1 infection and screened with standardized neurologic questionnaires and neurologic examination. Individuals also receive nerve conduction velocities (NCV) and autonomic function testing (AFT). Evaluations are performed without knowledge of the serostatus of the participants.
Results: Over a 3 month period, 25 HIV seronegative (SN) controls and 21 seropositive (SP) subjects were screened. The mean age for each group was 36 and 33.6 and the male/female ratio 2.5:1 and 2.1:1, respectively. Of SP individuals, 17 were asymptomatic (CDC Groups II/III), 4 had ARC, and none had AIDS. None was taking azidothymidine. 81% of SP and 76% of SN subjects had one or more neurological symptoms or examination abnormalities. This difference was not statistically significant. Minor electrophysiological abnormalities were detected in 3 of 13 SP and 5 of 26 SN subjects. None had autonomic function test abnormalities.
Conclusions: Among these subjects, the rate of neurologic abnormalities was high for both HIV-1 SP and SN individuals. These preliminary results will be expanded by recruitment of additional participants and longitudinal study.

Th.B.P.207 SUBCLINICAL NEUROPSYCHOLOGICAL AND PERIPHERAL ABNORMALITIES IN HIV+ PATIENTS

Cabo, Pedro*;Mangone,C*;Pérez,H*;Casiró,A*;Dellepiane,C*; Muchinik,G**,et al.
*Hospital Fernández,**IIHEMA,Academia Nacional de Medicina,Buenos Aires, Argentina.

Objective. To define the appearance of subclinical neuropsychological and peripheral manifestations in HIV+ neurologically asymptomatic patients(Pt).
Methods. Forty-five Pt(7 AIDS,38 ARC)were examined with brainstem-evoked responses(BAER), endogenous-evoked related potential(P 300 Wave), sensory and motor nerve conduction velocities, neuropsychological tests for verbal and visual memory(Wechsler's scale), associative learning-language(Wais, Western Aphasid Battery), abstract and rational thought, praxias and gnosias, kinetic family test and H.T.P.test.
Results. P 300 Wave and BAER showed anomalies in all AIDS Pt but not in ARC ones. Ten out of 14 ARC Pt without clinical evidence of polyneuropathy had slowed sural sensory nerve conduction velocity.Word fluency, abstract thought, verbal and visual memory were the most frequently and earliest neuropsychological functions affected. Drawings pointed out psychopathic, paranoic and evasive features.
Conclusion. Subclinical abnormalities found in our study support other evidences that HIV is associated with CNS dysfunctions. P 300 Wave and BAER are not suitable to search for early cognitive involvement, while sensory nerve conduction velocity is a useful neurophysiological technique to detect subclinical peripheral involvement. Both neurophysiological and neuropsychological assessment should be included for all HIV+ Pt.

Th.B.P.208 MULTIVARIATE STATISTICAL DETERMINATION OF INCIDENCE AND CHARACTER OF COGNITIVE IMPAIRMENTS IN HIV PATIENTS.

Brouwers, Pim, Mohr, E., Hendricks, M., Claus, J., Young, M., Pierce, P.
Georgetown University and National Institutes of Health, Washington DC, USA.

Studies of cognitive impairments in HIV patients and specifically those with the AIDS Dementia Complex have used deviations from control values and cut-off scores as their criteria for determination of impairment or dementia. The main objective of this study was to develop instead a multivariate statistical approach based on data of patients with actual neurodegenerative disorders to determine the incidence and character of dementia seen in patients with HIV disease. Discriminant analysis on the neuropsychological data of Alzheimer's (AD) and Huntington's (HD) patients as well as Normal Controls (NC) was used to develop a highly accurate (98.5% correct, p< .001) formula by which patients were classified as 'NORMAL' or 'DEMENTED'. If patients were classified as 'demented' the same technique also indicated with a high degree of accuracy (79% correct; p< .001) whether their impairments resembled more a subcortical (HD-like) or cortical (AD-like) dementia.

Using this rule on patients with Parkinson's disease (PD) indicated a high degree of dissimilarity between the AD and PD patients (p< .005) and a high degree of similarity between the HD and PD patients (p> .40) validating the use of the obtained formula since PD may be considered another example of a subcortical dementia.

The thus validated discriminant function was then used to classify our HIV patients, which indicated that 65% were classified as normal while 35% were classified as demented. Of the HIV patients classified as demented 83% showed a subcortical and 17% a cortical pattern. This distribution was significantly different from the AD group (p< .002) but was similar to the HD group (p> .50).

These data suggested that the HIV dementia has a subcortical character. Additional analyses contrasted the identified HIV subgroups (AD, HD, NC-like) on other cognitive, affective, hematologic and immunologic measures.

(This work was supported in part by a grant from AMFAR.)

Th.B.P.209 PERIPHERAL FACIAL PALSY AS A PREDICTIVE INDICATOR OF HIV INFECTION IN CENTRAL AFRICA.

L. Bélec*, P.M.V. Martin*, E. Vuillecard**, B. Di Costanzo**, E. Schuller***, A.J. Georges*
* Pasteur Institute, BP 923, Bangui, CAR; ** National Hospital BP 943, Bangui, CAR; *** Neuro-Immunological Department Salpétrière's Hospital, Paris, France.

Objective. To study consecutive cases of peripheral facial palsy (PFP) seen in 1988 in Bangui Hospital, paying special attention to HIV infection.
Methods. 10 male and 15 female (average age: 30) who presented with acute PFP were clinically examined, then investigated for HIV antibodies, tuberculin test, T4/T8 ratio, CSF analysis(when possible).
Results. 17 patients (7 men and 10 women, all African) had HIV1 antibody at the time of the onset of the PFP. 1 woman seroconverted within 3 months after first examination. Eleven were healthy HIV1-carriers, 6 had ARC and 1 met the CDC criteria of AIDS. In 6 cases, an influenza-like syndrome was present, associated in 3 cases with Herpes zoster eruption. The other 10 cases resembled Bell's palsy. In 1 case, the CSF was normal while for 1 other case, immunological pattern of meningitis was noted. In 2 cases, typical albumino-cytologic dissociation of CSF, suggesting unusual polyradiculoneuritis was observed.
Conclusion. PFP is an heterogeneous HIV manifestation, happening at any stage of the HIV infection, with various types of presentation, and several physiopathological mechanisms. Moreover, the positive predictive value of PFP in Central Africa (72%), for HIV infection, is remarkably high.

Th.B.P.210 DECLINING INCIDENCE OF AIDS DEMENTIA COMPLEX AND HIV-1 ANTIGEN DETECTION IN THE CEREBROSPINAL FLUID FOLLOWING SYSTEMATIC ZIDOVUDINE TREATMENT

Portegies, Peter *,**; De Gans, J.*; Derix, MMA *; Danner, SA***; Lange, JMA **,***; Goudsmit, J.** Departments of Neurology*, Virology** and Internal Medicine***, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands.

Objective. To determine the incidence of AIDS dementia complex (ADC) and HIV-1 antigen detection in the cerebrospinal fluid (CSF), related to the introduction of zidovudine treatment.
Methods. All patients with symptomatic HIV-1 infection and neurological complaints, who were seen at the AIDS-unit of the Academic Medical Center, between October 1982 and December 31th 1988 were examined by a neurologist. Retrospectively the incidence of ADC was determined for each year. HIV-1 antigen detection in the CSF was compared between two groups: 1. CSF-samples obtained between October 1982 and January 1988 and 2. CSF-samples obtained in 1988.
Results. The number of AIDS-patients with neurological complaints (every year almost 70% of all AIDS-patients in our hospital) increased from 1 patient in 1982 to 88 patients in 1988 (total number n=250). Zidovudine was introduced in The Netherlands in May 1987. The number of patients classified as having ADC increased every year till 1986: 1982: 0/1 (0 of 1 patient examined), 1983: 1/7, 1984: 3/6, 1985: 5/19, 1986: 15/60, remained stable in the first half of 1987 (n=10/30), started to decline in the second half of 1987 (n=6/47), and decreased sharply in 1988 (n=2/88). Between October 1982 and January 1988 CSF-samples were collected from 85 AIDS-patients for HIV-1 antigen detection. Twenty were HIV-1 antigen positive (12 patients with ADC, 8 without). In 1988 82 CSF-samples were available: in only six samples HIV-1 antigen was detectable (2 patients with ADC, none of them was using zidovudine).
Conclusion. While the total number of AIDS-patients with neurological complaints is still increasing, the incidence of ADC and HIV-1 antigen detection in the CSF is declining. The decline started after introduction of zidovudine.

Th.B.P.211

A CASE DEFINITION OF AIDS DEMENTIA COMPLEX FOR USE IN AFRICAN PATIENTS

Perriens, Joseph *; Mussa, M. **; Lusbeya, M. **; Kayembe, K. **; Colebunders, R. ***; Kapita, B. ****.
* Projet SIDA, ** CNPP, Kinshasa, Zaire, *** CDC, Atlanta, USA, **** Mama Yemo Hospital, Kinshasa, Zaire.

Objectives. To develop and evaluate a clinical case definition for AIDS dementia complex (ADC) for use in African patients.
Methods. We evaluated 233 patients, hospitalised in 2 Internal Medicine wards of Mama Yemo Hospital, Kinshasa, Zaire, with a comprehensive clinical and neurological exam, elementary neuropsychological tests, and HIV serology.
Results. One hundred twenty five (54%) patients were HIV(+). Neurologic manifestations associated with HIV seropositivity (p<0.02) were:

Sign/Symptom	% HIV(-)	% HIV(+)	Spec(%)*	PPV(%)**
Personality changes	33	52	67	65
Social withdrawal	21	41	79	70
Difficulty concentrating	9	26	91	77
Slowing of mentation	10	24	90	72
Insomnia	21	39	79	70
Difficulty walking	26	42	74	66
Difficulty dressing	16	33	84	71
Palmomental reflex	13	26	87	70
Tremor of hands/fingers	6	24	94	52
Generalized hyperreflexia	3	16	97	87

* specificity and ** positive predictive value for HIV seropositivity.
A clinical definition of ADC requiring at least 5 of these signs/symptoms had a sensitivity of 23%, a specificity of 94% and a PPV of 83% for HIV seropositivity.
Conclusion. Neurologic manifestations occur frequently among African HIV(+) hospitalized patients. A clinical case definition of ADC had a high specificity and PPV for HIV seropositivity in hospitalized Zairian patients.

Th.B.P.212

NEUROPSYCHOLOGICAL MANIFESTATIONS OF HIV INFECTION: A PROSPECTIVE STUDY.

Chave, Jean-Philippe *; Thuillard, F.**; Assal, G.** and Glauser, M.P.*.
* Division of Infectious Diseases and ** Division of Neuropsychology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.

Objective. HIV encephalopathy is clinically characterized by cognitive, motor and behavioral signs, and is classically observed in full-blown AIDS. However, it has been suggested that cognitive defects might already be present in earlier stages of HIV infection. The objective of this study was to assess the prevalence of cognitive signs in various stages of HIV infection.
Methods. Since 1.4.1986, a neuropsychological evaluation was proposed every 6-12 months to HIV-positive persons cared for at our institution, regardless of the stage of their HIV infection. In addition, all participants underwent general and neurological examinations. Patients with CNS opportunistic, neoplastic or metabolic pathologies were excluded.
Results. Sixty-eight neuropsychological examinations have been performed in 55 persons (23 homosexuals, 26 drug addicts, 5 heterosexuals and 1 recipient of blood products). Moderate to severe cognitive defects have been demonstrated in 23 cases, and were associated with motor and/or behavioral signs in 5/23. The table describes the distribution of cognitive defects recorded during the 68 examinations, according to the stages of HIV infection (in stage IV, a patient may have ≥ 1 disease stage):

HIV clinical staging (CDC classification) :	II	III	IVA+IVC2(ARC)	IVB+C1+D(AIDS)
Number of examinations :	10	17	20	21
Cognitive defects (%) :	3(30)	4(24)	5(25)	11(52)

Conclusion. Neuropsychological signs of HIV encephalopathy could be detected in a significant proportion of the first stages of the infection. Cognitive signs can be easily missed during general medical examination, but could have important socio-professional consequences and could respond to zidovudine therapy. The occurence of such defects in the first stages of HIV infection should be searched for when performing a medical evaluation in HIV-infected patients.

Th.B.P.213

CNS LESIONS IN AIDS:ANALYSIS OF 44 PATIENTS

Roberto Luzzati,E.Concia,L.Bontempini*,M.Malena,R.Mazzi and D.Bassetti.Institute Infectiuos Diseases,Verona *Department Pathology,Verona,Italy

Objective.Central nervous system (CNS) is frequently involved in AIDS.We investigate type and prevalence of CNS involvement in our AIDS patients observed during the period 1984-1988.
Methods.Fourtyfour patients were studied.Diagnosis was mostly based on imaging techniques (CAT,NMR) and on microbiological investigations on CSF.
Results.Of 44 patients,28 (63.6%) had CNS disease.The following conditions were recognized(the cases identified intravitam are indicated in brackets): toxoplasmosis 11(10),HIV encephalitis 10(10),criptococcosis 4(4),lymphoma 3(1), HIV myelitis 2(2),CMV encephalitis 1(0),HSV encephalitis 1(0),tuberculosis 1 (1),PML 1(1),KS 1(0),H.capsulatum encephalitis 1(0).Various associations were observed in 5 patients (3 cases died).Twelve patients with CNS involvement are surviving (42.8%),whereas 11 of the patients without CNS lesions are still alive (68.7%).
Conclusion.We observe high prevalence of CNS conditions and toxoplasmosis,HIV encephalitis,criptococcosis particularly,in our AIDS patients.CNS involvement appears often asymptomatic and the earlier recognition of some curable diseases emerges as target for clinical research.

Th.B.P.214

GUILLAIN-BARRE SYNDROME IN HIV INFECTION: EXPERIENCE FROM AN AFRICAN CENTER

Thornton,Charles; Latif, A S
University of Zimbabwe School of Medicine, Harare, Zimbabwe

Objective.To determine the clinical features of HIV-related Guillain-Barre Syndrome (GBS) in this region.Methods.We prospectively examined 23 consecutive adult patients admitted to the teaching hospitals with inflammatory demyelinating polyneuropathy for serum reactivity against HIV by ELISA. All patients were seen by a neurologist, and had CSF examined. 22 of 23 patients had electromyography/nerve conduction studies.Results.20 patients had GBS, 3 had chronic inflammatory polyneuropathy (CIP). None of the CIP patients were HIV positive. Clinical features of GBS were similar in HIV positive and negative patients, except as shown in table.

GBS patients	HIV neg(n=10)	HIV pos (n=10, all were strong pos)
generalized lymphadenopathy	0	10 (p< .05)
STD in previous 5 years	1	8 (p< .05)
CSF pleocytosis > 5 WBC	1	5
coexistent neurologic diagnosis	0	4(e.g. myelopathy,neurosyphilis)
mechanically ventilated	4	0

Of the 10 HIV positive GBS patients, 8 were previously asymptomatic, none had AIDS. During the period of maximal disability, all GBS patients were unable to walk independently. The only fatality was in a HIV negative GBS patient, 18/19 other GBS patients were followed well into the recovery phase. Conclusion.HIV-related GBS accounts for a significant proportion of GBS in this area, tends to occurs early in the HIV infection, and carries a good prognosis for recovery from the neuropathy.

Th.B.P.215

Long term effects of treatment with zidovudine on neuropsychological function in patients with ADC.

Reinvang,Ivar, Frøland,SS and Lundervold A.J.
Rikshospitalet, Oslo 1, Norway.

Objective: To evaluate effect of zidovudine treatment on neuropsychological and immunological parameters during 10 months of follow-up in patients with ADC.
Subjects: 8 patients with AIDS were studied. According to neuropsychological test results before start of treatment, 6 had ADC and 2 had no manifestation of ADC.
Tests: A psychometric battery was repeated at 5 and 10 months after start of treatment. In addition a special battery of computerized tests was performed at 6-8 week intervals in some of the patients.
Results: A stable level of performance was found in the two initially normal patients throughout the study period. All the ADC-patients showed initial improvement of performance, but a variable clinical course was then seen, with decline of performance to baseline, death before the second follow-up, or continued improvement. The CD4 cell count in blood did not predict neuropsychological response to treatment.
Conclusion: Zidovudine-treatment leads to improved neuropsychological performance in ADC-patients, but the long term benefit is variable with therapeutic failure after 4-6 months in some patients.

Th.B.P.216

PREVALENCE, TREATMENT, AND COSTS OF MENTAL DISORDERS AMONG PERSONS WITH AIDS

Hidalgo, Julia.*; Schaerf, F.**; Larson, D.***
*MD Department of Health and Mental Hygiene, Baltimore, MD, U.S.A.; **Johns Hopkins University School of Medicine, Baltimore, MD., U.S.A.; ***National Institute of Mental Health, Baltimore, MD. U.S.A.

Objective. The prevalence of mental, neuropsychiatric, and addictive disorders among persons with AIDS has been estimated to be high. It is unclear, however, what impact presence of these disorders has upon therapeutic regime and costs of persons with AIDS. This paper applies a model automated AIDS information system to measure use and direct costs of AIDS-related treatment across providers and payers. Methods. Institution and community-based services used by 1,300 Maryland residents with AIDS during the period between 1981-1987 were retrospectively studied. An automated information system made up of longitudinal, person-based files serves as the basis of this study. The system links HIV registry, vital statistics, hospital, long term and chronic care, community-based service, and health insurance claims records to measure the nature, volume, and costs of service use associated with AIDS treatment during the period between diagnosis and death. Results. Incidence of mental, neuropsychiatric, and addictive disorders and co-morbidities are reported and course of treatment is described. Direct costs, charges, source of payment, and mix of general and mental health services are assessed. Factors contributing to use of mental health services such as socio-demographic characteristics, transmission group, severity of illness, and survival time. Conclusion. Findings of this study are useful to policy makers at the local, State, and Federal levels in planning service and financing required to meet the needs of persons with HIV disease.

Th.B.P.217 NEUROLOGICAL DISTURBANCES ASSOCIATED WITH HIV INFECTION: EXPERIENCE AT AN AFRICAN CENTER

Thornton, Charles; Latif, A; Houston S
University of Zimbabwe School of Medicine, Harare, Zimbabwe

Objective.To determine the neurologic disturbances associated with HIV in this region.Methods.Over 14 months, we prospectively examined 74 adults with major neurologic disturbance and HIV infection. HIV serologic testing was by ElISA and, where appropriate, WB. Patients were seen by a neurologist, and brain CT scans obtained when needed. Cases with non-disabling polyneuropathy, uncomplicated zoster, and mild cognitive impairment were excluded.Results.Neurologic disturbance was the presenting feature of HIV in 62 patients, 14 had AIDS at presentation. Diagnoses were:
MENINGITIS(17):cryptococcal 9, aseptic 5, tuberculous 2, pneumococcal 1
MYELOPATHY - ACUTE(5):zoster myelitis 2, bilharzial 1, CU(cause unknown) 2
- CHRONIC(8):coexistent HTLV-I 2, compressive(lymphoma) 1, CU 5
PSYCHIATRIC/DEMENTING(10):Psychosis with organic features 5, presumed HIV encephalopathy 4, parenchymal neurosyphilis (dementia paralytica) 1
FOCAL BRAIN LESION - VASCULAR(5):meningovascular syphilis 2, following zoster opthalmicus 1, intracerebral hemorrhage 1, ischemic stroke CU 1
- OTHER(8):cysticercosis 2, toxoplasma 1, tuberculoma 1, CU 4
PERIPHERAL/OCULAR(19):Guillain-Barre syndrome 10, CMV retinitis 1, retinal vein occlusion 1, cranial neuropathy 7
OTHER(3):Juvenile onset parkinsonism 1, severe postural tremor 1, relapsing-remitting disease of optic nerves and central white matter 1
Conclusion.Neurologic disturbance was a common presenting manifestation of HIV. 3 patients had parasitic disease of the CNS, 3 had neurosyphilis.

Th.B.P.218 EFFECTS OF AZIDOTHYMIDINE ON NEUROPSYCHOLOGICAL PERFORMANCE IN ASYMPTOMATIC AND SYMPTOMATIC HIV-1 INFECTION: THE MULTICENTER AIDS COHORT STUDY (MACS)

McArthur, Justin C.*; Miller, E.N.**; Selnes, O.A.*; Becker, J.***; Cohen, B.A.****; Starkey, D.*; et al
Johns Hopkins Medical Institutions, Baltimore, MD, **University of California, Los Angeles,
*** University of Pittsburgh, PA, ****Northwestern University, Chicago, IL, USA

Objective: To examine the effects of azidothymidine (AZT) on neurological status and neuropsychological performance of homosexual/bisexual men in the Multicenter AIDS Cohort Study.
Methods: Standardized measures including a neurological questionnaire, neurological examination and neuropsychological tests (NP) were administered twice at 6-12 month intervals to 543 seronegatives, 463 HIV-1 seropositives (SP) in CDC Groups II or III and 46 individuals with ARC or AIDS. None was taking AZT at baseline; clinical status, CD4% and AZT use were assessed at follow-up (F-up).
Results:

		Neuropsychological Testing				
		Abnormal Baseline	Abnormal Follow-up	Abnl baseline, Normal F-up	Normal baseline, Abnormal F-up	Change CD4%
Asymptomatic SP						
No AZT	n=437	11%	13%	6%	9%	-0.66
AZT	n= 26	11%	8%	4%	0%	+0.35
Symptomatic SP						
No AZT	n= 26	12%	35%	4%	27%	-0.77
AZT	n= 20	20%	25%	10%	15%	-2.36

Among asymptomatic SP's, 9% of AZT non-users had worsening of NP performance at follow-up compared to 0% in AZT users. Among symptomatic SP's, NP performance normalized at follow-up in 2/20 AZT users compared to 1/26 AZT non-users, and 15% vs 27% showed worsening. No differences were observed in subsequent neurological symptoms, examination findings or CD4%.
Conclusion: These data suggest that NP performance can stabilize or improve after initiation of AZT. These preliminary observations will be expanded by analysis of subsequent data collection.

Th.B.P.219 NATURAL HISTORY OF CENTRAL NERVOUS SYSTEM (CNS) IMPAIRMENT IN HIV INFECTION

M. Gentilini. Christine Katlama, P. Duneton, F. Chieze, H. Agut, P. Brunet,
Hôpital de la Pitié-Salpêtrière - Paris. FRANCE.

Objective. To ascertain the early neurological changes and progression of HIV invasion of CNS.
Methods. Cohort study of HIV infected patients with clinical and neurological examination, biological (CSF study/CD4 cell counts), virological (HIV antibody synthesis, culture and PCR in CSF), neuropsychological testing (NP), electrophysiological testing (EP) and MRI examinations every 6 months. Partial and preliminary results are shown here.
Results. 62 patients have been enrolled since 03/87 : they were (group 1 n=31 : CDC stage II (n=18) or stage IV C2 (n=13) and group 2 n=31 : CDC stage IV C1/D). CSF abnormalities were present in 34/36 (71%) with no difference between group 1 and 2 NP testing was impaired more frequently in group 2 (10/20) than in group I (11/30) although difference is not significative. EP defects were seen in 7/26 in group 1 and 9/19 in group 2. HIV was detected in culture of 4/20 CSF. Intrathecal synthesis and detection of DNA by PCR are under evaluation.
Follow up. 10 patients died with neurological dysfonction in 3 cases ; histological studies are on going ; 10 patients were evaluated at 6e month : stable NP testing (6/10), improvement (3/10) deterioration 1/10.
Conclusion. Evidence of early virological invasion of CNS by HIV is frequent ; mild abnormalities of neuropsychological testing can be transitory ; long term evaluation is required to evaluate the pathogenesis of potential HIV brain damage.

Th.B.P.220 NEUROLOGIC MANIFESTATIONS IN HIV INFECTION. ANALYSIS OF 217 PATIENTS.

Galgani S.**; Piazza G.**;Antonucci G.*; Armignacco O.*; Narciso P.*;
Visco Giuseppe* et al.
U.S.L. RM/10 "S. Camillo" Hospital, Dept.of Neurology** & "L. Spallanzani" Hospital, Dept. of Infectious Diseases*,Rome,Italy.

OBJECTIVE. To estimate prevalence of the nervous system involvement both in different risk groups and as initial manifestation of AIDS.
METHODS.217 patients (pt) with HIV infection at different stages, all presenting neurological symptoms or signs were evaluated through some of the following diagnostic procedures:CSF examination, EEG, CT scans, MRI, EMG, Visual Evoked Potential (VEP), Brainstem Auditory Evoked Potential (BAEP),Somatosensory Evoked Potential (SEP), Single Photon Emission Compiuted Tomography (SPECT).
RESULTS

	Prevalence in risk groups				
	drug addicts	homosexuals	others	total	p
Opportunistic Infections	37 (22%)	11 (32%)	3 (18%)	51 (23,5%)	NS
"HIV related diseases"	69 (41%)	19 (56%)	12 (70%)	100 (46%)	NS
Tumors	11 (6,5%)	3 (9%)	1 (6%)	15 (7%)	NS
Others	49 (30,5%)	1 (3%)	1 (6%)	51 (23,5%)	<0.001

Neurological complication were the first manifestation of AIDS in 61 (29%) of all our AIDS pt with neurological symptoms (212); among them O.I. was the cause in 33 pt (16%), HIV-encephalopathy in 19 (9%) and primary lymphoma in 9 (4%). Other neurological complications (dismetabolic encephalopathy, seizures, etc) were more frequently found in drug addicts (p<0.001). Among "HIV related diseases", peripheral neuropathies were more frequently in drug addicts than in homosexuals and others (p<0.05) but encephalopathy was more common in the non addicts (p<0.05).

Th.B.P.221 NEUROPSYCHIATRIC FINDINGS IN HIV INFECTED PATIENTS AT AN INFECTIOUS DISEASE CLINIC IN KINSHASA, ZAIRE

Kayembe. Kalula *, Luabeya MK *,***, Nussa M *, Kayembe K **, Izzia K **, Kashala TD ***
* Dept of Neurology, ** Dept of Internal Medicine, *** School of Public Health, University of Kinshasa, Kinshasa, Zaire

Objective. To describe HIV related neuropshchiatric disorders in everyday outpatient consultation in Kinshasa.
Methods. A team of neuropsychiatrists examined all HIV+ patients attending an outpatient consultation for infectious diseases at the Kinshasa University Clinics.
Results. Among 42 outpatients seen in one day with various infectious disorders, 16 (38%) were HIV+ (9 males, 7 females, ages 21-54 years). They had the following complaints: vertigo, loss of libido, headache, sleep disturbance, tinnitus, post zoster pain, hearing impairment, gait disturbances, irritability, seizures, paresthesia, urinary sphincter disturbances. Nine (58%) of these had abnormal neuropsychiatric signs such as frontal release signs (5), hyperreflexia (5), memory disturbances (2), bilateral grasping reflex (1), hyperpathia (1), hypoacusia (1), coma (1), neck stiffness (1) and tremor (1).
Conclusions. Neuropsychiatric signs are common in HIV+ outpatients in Kinshasa. Considering the small number of neurologists and psychiatrists in Zaire, detection and early proper management of HIV+ patients with neuropsychiatric disorders is already a major health problem.

Th.B.P.222 MARKERS OF HIV INFECTION IN THE CNS

Sonja Žerjav, Dj.Jevtović,B.Brmbolić,V.Šuvaković, M.Šašić
Institute for infectious and tropical diseases,Belgrade, Yugoslavia

Objective:Paired serum and CSF samples of HIV infected persons(ARC or AIDS) with neurological signs(23) and without NS(10) have been tested.
Methods:ELISA for HIV Ab and Ag,ELISA for beta-2 microglobuline,RID for albumin,globulin(IgG,IgM and IgA),Tibbling-Link index for intratechal synthesis of immunoglobulin,co-culture of Ly-Mo for isolation of HIV.
Results:

		IgG%	Alb/	Alb%	beta-2m/	HIV isol.	ITS IgG
Patiens with NS(23)	S	56%	13%	39%	76%	84%	
	CSF	4%	13%	13%	46%	22%	65%
Patients with-ot NS(1o)	S	60%	10%	60%	80%	60%	
	CSF	0%	20%	0%	20%	0%	0%

Conclusion:
The most Important differences between this groups of HIV infected patients with N S and without NSare in elevated IgG in CSF,reduced albumin,elevated beta-2 microglobuline,more percent of HIV isolation from CSF and proof of intratechal synthesis of IgG in the group with NS.

Th.B.P.223 CYTOKINES AND IMMUNOGLOBULINS (Ig) IN CEREBROSPINAL FLUID (CSF) OF ANTI-HIV-1 POSITIVE, ANTI-HTLV-I NEGATIVE ASYMPTOMATIC MEN.

Klimas, N.G.*, Berger, J.*, Spector, S.**, Friedman, H.**, Ashman, M.* and Fletcher, M.A.* *University of Miami, Miami, FL and ** University of South Florida, Tampa, FL USA.

Objective To determine the presence and amount of IgG and abnormal Ig bands as well as cytokines, interferon gamma (IFNG), interferon alpha (IFNA) interleukin-2 (IL-2) and tumor necrosis factor (TNF), in the CSF of anti-HIV-1 positive asymptomatic men, obtained at baseline for a longitudinal study of the neurological effects of HIV-1 infection.
Methods CFS was obtained from 53 anti-HIV-1 (+), anti-HTLV-I (-) asymptomatic men. IgG was measured by nephelometry, oligoclonal bands by agarose gel electrophoresis and immunofixation, IFNG by RIA and by bioassay, IFNA by bioassay, TNF by bioassay, IL-2 by ELISA.
Results Eighteen (34%) of the samples had elevated IgG (>6.4mg/dl). Thirteen % had abnormalities of CFS Ig protein patterns; 6 had oligoclonal bands and one had an IgG, kappa monoclonal protein. Only 1 sample had measurable IL-2 (2.5 ng/ml); the remainder were < 0.3ng/ml. None of the samples had measurable amounts of IFNG, IFNA or TNF.
Conclusions In these asymptomatic men, prior to any HIV-1 associated neurologic complications, elevations of immunoglobulin G and abnormal Ig bands were frequently present, suggesting either infection within the central nervous system (CNS) or B cell dysregulation. The absence of appreciable amounts of IFNs in the CSF suggests either impaired ability to produce IFN, or lack of appropriate stimulation, such as an infection within the CNS. The absence IL-2 (except in 1 sample) and TNF also suggest either lack of stimulation, or inability to produce these cytokines. (supported by 1 PO1-NS-25569)

Th.B.P.224 SEROTONIN METABOLITE DEFICIENCY IN HIV INFECTION AND AIDS.

Britton, Carolyn B.; Kranzler, S.; Naini, A.; Coté,L.
HIV CENTER, Columbia University College of Physicians and Surgeons, New York, New York, U.S.A.

Objective: To determine if cerebrospinal fluid biogenic amine metabolites are altered in patients with HIV infection or AIDS.
Methods: Biogenic amine metabolites were analyzed in seventeen cerebrospinal fluid specimens from fifteen patients with HIV infection or AIDS using high performance liquid chromatography.
Results: Levels of the serotonin metabolite, 5-hydroxyindoleacetic acid (5-HIAA), were profoundly reduced in 13 samples from 11 patients: range 3.8-17.1 ng/ml; mean 10.1 ng/ml; normal ≥30 ng/ml = 33% normal level. Homovanillic acid levels (HVA, a metabolite of dopamine) were variably affected: range 9.4-59 ng/ml; mean 22.9 ng/ml; normal ≥30 ng/ml = 76% normal level. In four patients, both 5-HIAA and HVA levels were borderline or normal. Four of the eleven patients with reduced 5-HIAA levels had only presumed HIV-related dementia and/or myelopathy and the others: other cerebral infections-3; thoracic zoster-1; stroke-1; cauda equina syndrome-1; syncope-1. One of the four patients with borderline or normal results was treated with phenytoin, a drug reported to increase serotonin synthesis in brain, while one each had toxoplasmosis, pulmonary TBC, unknown HIV status with risk.
Conclusions: The data suggest an early, possibly selective, inhibitory effect of HIV infection on serotonin synthesis. Although HIV is not detected in neuronal cell populations, the presence of the virus in brain may cause alterations in neuronal cellular metabolism and neurotransmitter synthesis that result in the cerebral and spinal cord syndromes attributed to the virus.

Th.B.P.225 INTRATHECAL SYNTHESIS OF FREE LIGHT CHAINS IN HUMAN IMMUNODEFICIENCY VIRUS TYPE 1 INFECTED PATIENTS.

Gallo P., Pagni S., Piccinno M.G., De Rossi A.*, Chieco-Bianchi L.*, and Tavolato B.
Institutes of Neurology and * Oncology,
University of PADOVA, ITALY.

INTRODUCTION. In order to further characterize the humoral immune response within the central nervous system (CNS) in HIV-1 infected patients, we studied the presence of kappa and lambda free light chains (FLC) of immunoglobulins (Ig) in cerebrospinal fluid (CSF).
MATERIALS and METHODS. CSF was obtained from 25 patients, ranging WR1-WR6, with or without neurological complications. FLC patterns were analysed by isoelectric focusing and SDS-electrophoresis followed by protein transfer analysis. Albumin CSF/serum ratio, IgG index, IgG Hyp Funct, HIV-1 Ab,HIV-1 Ag, and clonal distribution of IgG,IgA and IgM, were routinely assessed.
RESULTS. FLC with restricted heterogeneity, in terms of isoelectric point or molecular weight, were the most frequent CSF immunologic abnormality, and were detected in 80% of the samples, even in the absence of oligoclonal IgG. Lambda FLC were more frequently found than kappa FLC. Moreover, FLC dimers showed more heterogeneous and prominent patterns than FLC monomers.
DISCUSSION. The presence of oligoclonal FLC in the absence of oligoclonal Ig might be the expression of a deregulation in Ig production by intrathecally segregated B lymphocytes in HIV-1 infected patients.

Th.B.P.226 ACTIVATION OF THE CELLULAR IMMUNE SYSTEM IN THE CNS OF HIV-1 INFECTED INDIVIDUALS

Sönnerborg A*,**, von Stedingk LV*, Hansson LO***, Strannegård Ö*.
* Central Microbiological Laboratory, Stockholm, Sweden, ** Roslagstulls Hospital, Karolinska Institute, Stockholm, Sweden, *** Danderyds Hospital, Stockholm, Sweden.

Objective. To study the activation of the cellular immune system in the CNS of HIV-1 infected persons.
Methods. Neopterin and beta-2-microglobulin (B2M) concentrations I CSF and plasma were measured in 56 individuals in various stages of HIV-1 infection by RIA or ELISA. Cultivation attempts of HIV-1 from CSF and plasma were performed.
